Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

VOL. XLIII. NEW YORK, SATURDAY, JANUARY 2, 1904. No. 1.

ELECTRICAL WORLD AND ENGINEER

Published weekly by the

McGRAW PUBLISHING CO.

114 LIBERTY STREET, NEW YORK.

TELEPHONE CALL: 7605 CORTLANDT. CABLE ADDRESS: ELECTRICAL, NEW YORK.

EDITED BY T. C. MARTIN AND W. D. WEAVER.

CHICAGO OFFICE - - - - 1139 Monadnock Block.
PHILADELPHIA OFFICE - - - - - - 929 Chestnut Street.
EUROPEAN OFFICE, Hastings House, Norfolk St., Strand, London, Eng.

TERMS OF SUBSCRIPTION.

United States, Canada or Mexico	Per year, $3.00
Foreign Countries, within the Postal Union	6.00
Great Britain and Ireland	25 shillings
Germany	25 marks
France	31 francs
Single copies	.10

Remittances for foreign subscriptions may be made through our European office. In requesting your address changed give OLD as well as new address.

Entered as second-class mail matter at the New York Post Office.

NEW YORK, SATURDAY, JANUARY 2, 1904.

CONTENTS.

ELECTRICAL PRODUCT IN 1903.

In accordance with our usual custom we present herewith an estimate of the production of electrical apparatus in 1903. As will be seen, the figures given below represent a total output of $158,-650,000 as compared with $139,950,000 in 1902. There is good reason for believing that the figures of 1902 were correct, but a little doubt exists as to some of the items last year. As has been clearly shown by the census figures of the last twenty years, the usual rate of increase in electrical manufactures each year has been on an average from 15 to 20 per cent., taking good years with bad. During 1902, which was one of unparalleled activity, there is every reason to suppose that the production increased over the preceding year a full 20 per cent., but we are justified in questioning as large a gain in 1903.

ESTIMATED PRODUCTION, 1903:

Dynamos	$17,000,000
Transformers	5,000,000
Switchboards, for lighting and power	2,750,000
Motors, for all purposes	30,000,000
Storage batteries	4,500,000
Primary batteries	1,250,000
Carbons	2,000,000
Arc lamps	2,250,000
Incandescent lamps	5,500,000
Lighting fixtures	3,750,000
Telephonic apparatus	25,000,000
Telegraphic apparatus	2,000,000
Insulated wires and cables, submarine cables	30,250,000
Conduits, interior and underground	1,750,000
Rheostats, heating and cooking apparatus	2,500,000
Annunciators	250,000
Electric clocks	150,000
Lightning arresters, fuses, etc.	750,000
Measuring instruments	3,000,000
Miscellaneous apparatus	19,000,000
	$158,650,000

It will be seen that the figure of $158,000,000 represents an increase of about 10 per cent. all around during the year, and when it is remembered how sharp a check was sustained by many lines of industry in the year which has just closed it is fair to assume that such a rate may broadly represent the total, even while some of the items may be slightly more or less "off the spot." Telephonic activity, for example, in 1902, by more than one estimate, was represented by about $21,000,000. The past year it is set down at $25,000,000—a gain of 20 per cent. It may have been even higher than that, but there are elements of doubt. Electric motors in 1902 were estimated at $27,000,000 including all kinds. Last year they are put down for $30,000,000, and while this is only an increase of 10 per cent. and may be underestimated, it is undeniable that some of the largest concerns are hardly supposed to have shown a gain superior to that during the year. It will be noted that insulated wires and cables and submarine cables are set down for slightly in excess of $30,000,000, which is a gain of $2,500,000 over 1902. This seems an enormous figure, but it is substantiated by the reports of the companies themselves in 1900, and represents consumption in every other branch of the electrical field. It will of course be understood that such an item appears again in other branches, as, for example, the insulated wire used in dynamos, motors, telephone switchboards, etc., and to that extent it represents a duplication of product, but there is no way of avoiding such a feature in these calculations.

Altogether the showing of the year is quite satisfactory, and we have no reason for doubting that the production in 1904 will fall below this figure. Allowing for errors and possible overestimates in one direction off-set by underestimates in another, it stands to reason that an industry which has already attained a production of $150,000,000 a year in manufactured goods takes its place amongst the leading mechanical industries of the country. It must be recollected that all of this apparatus serves as a constituent of great systems and plants for railway work, lightning, telephony, telegraphy, etc., so that the actual increase in investment represented during the year, including real estate, buildings, line construction, track construction, engines, turbines, etc., may well represent not far short of $750,000,000. The annual increase in capitalization in the street railway field alone is now about $450,000,000 a year, and the other electrical industries grow in proportion, although, unfortunately, capitalization is not always investment.

Arnold Single-phase Electric Railway System.

Elsewhere we print an article by Mr. B. J. Arnold giving a description in full detail of his single-phase electric railway system, a preliminary account of which formed the subject of a communication by Mr. Arnold at the Great Barrington meeting in 1902 of the American Institute of Electrical Engineers. Mr. Arnold will have the sympathy of all who read the account given of the unfortunate series of delays, over a period of almost two years, which prevented a practical public demonstration of his system, and which culminated in the destruction of the apparatus by fire just prior to a public trial that had been set for the opening of the new year—a year which he in common with many others believe will inaugurate a new era in electric traction. Mr. Arnold, in the days when it was heresy to believe in the fitness of alternating current for railway work, took an open stand as its advocate, though, singularly enough, as an equally determined champion at an earlier period of the rotary substation system, and the first, we believe, to lay down such a system on a considerable scale, he had been a prime factor in establishing what for years deterred any attempts at development of alternating-current traction in this country. Believing that the solution of the problem lay in the use of single-phase and not polyphase power, he devised the system described in the article, which was experimentally tested in the early part of 1902. Had it not been for the most unfortunate series of delays, Mr. Arnold would have had the pleasure of giving the first public trial of a single-phase electric railway system operating commercially, and in electric traction would have figured as the pioneer in that art in virtue of such demonstration. The lack of such fortuitous record will not, however, obscure the value to alternating-current traction of his early and constant advocacy of the cause, and recognition of the stimulating effect which the announcement in 1902 of his system undoubtedly had in developing the single-phase situation.

The vital point of difference between the single-phase system of Mr. Arnold and the systems later developed is that all of the latter employ a commutator motor almost identical in construction with the direct-current motor, while the former uses a pure type of synchronous alternating-current motor. Since in this type the relative speed of the armature and field must always be constant, variation of operating speed is obtained by making both these members rotatable. In this manner the condition of synchronous speed with relation to the field and armature is maintained, while any operating speed between zero and synchronism is secured by rotating from an exterior source the field in a direction opposite to that of the armature; or a speed greater than synchronism may be obtained by rotating the field in the same direction as that of the armature. This exterior source consists of a compressed air outfit in connection with the car motor, which stores up energy when the motor car slows down, and gives it forth again when the car starts up; or the air storage can be increased at any time the car is running or is at rest, and the speed can be regulated at will. A salient advantage of the system is that an absolutely constant load can be maintained on the power house regardless of the stoppage of cars, and of the power required in acceleration. This follows from the fact that the car motor is always running, and when not delivering power to the car, is engaged in storing compressed air. The compressed air pumps are only idle when the car is running at synchronous speed; when reducing speed, air is being stored at a rate corresponding at each instant to the reduction of speed at that instant; and when the car is gaining speed, then is an expenditure of the stored energy corresponding to the rate of acceleration. Another advantage of the system is that a car can for a certain fixed period be deprived of any electrical supply and kept in motion by the compressed air auxiliary, as in passing through a town, in the streets of which it would not be advisable to install the high-tension supply conductor.

The disadvantage of the system is obviously the complexity introduced by the compressed air outfit, which doubtless also introduces a weight handicap. As the first practical working solution offered to the single-phase traction problem, this disadvantage was subject to offset by the great advantage of the high-tension current involved over the low voltage of the direct-current system. At present, however, the comparison is with the recent alternating-current systems, and it remains to be seen if their greater simplicity can be overcome by such advantageous features of the Arnold system as are not common to them.

The Telephone.

During the past year there have been no striking developments in the technical side of telephony, but the steady progress in the perfection of details, and especially of the minor ones, which have been so characteristic of the preceding several years, has shown no relaxation, as our weekly review of telephone invention has borne witness. The interest of inventors in automatic telephony has not abated, several new systems during the last year having been patented, and the older automatic systems have undergone steady improvement. The central energy system has become so thoroughly established in the art that an exchange not equipped for its employment may now be considered almost obsolete. A new field recently opened for telephony is in connection with railway working. The telephone, of course, has for some years been of much service as part of the dispatching system of electric railways, but its adaptation to the service of trunk line railroads has been a development of the past few years. Recently an impetus has been given to railway telephony by the perfection of a new and simple system for the simultaneous use of the same conductors for both telegraphy and telephony, and we are informed that a railway department has been established as a branch of the leading telephony organization of the country. This is not an innovation *per se,* since for ten years or more long-distance telephone lines have been utilized for telegraphic purposes. In the early stage and possibly to some extent even to-day, one who leased a private telephone line was not aware that his wires were also leased for two telegraphic circuits.

The advent of new systems and notable improvements in devices are widely heralded, but it is not generally realized what a great part the engineer, as distinguished from the inventor, has quietly played in placing telephony on its present efficient footing with respect to continuity of service, the extension of exchange service and in making possible reduction of rates. As an example, we may mention the use of lead-covered cables, which alone permits of properly distributing subscribers' lines in their present magnitude. Taking the case of great office buildings in the larger cities, each frequently containing several hundred telephones, a pole line of standard construction to feed such a building, assuming it to require 300 lines, would be some 160 feet tall, the cross arms beginning 20 feet from the street. The early types of telephone cable at once reduced the space required for such a number of wires to a few hundred square inches, while with more modern cables only some 16 square inches are required in which to conduct 300 pairs of wires. The step from the early lead cables with their large conductors, fibrous insulation and parafine filling with consequent high electrostatic capacity, to the modern small conductor cable having six or more times the number of conductors in the same bulk, was no small one, and arrived at only after the most careful study and co-operation between engineers and cable manufacturers. The situation in this connection has been still further ameliorated by the beautiful invention of Dr. Pupin, consisting in so distributing inductances along the line as to neutralize the disturbing effects of capacity, whereby transmission through cables of commercial proportions may be brought to equal or even exceed that through standard aerial lines.

A somewhat curious recent development as reflected in patent office issues, is in the provision of means to prevent infection from the mouthpieces of telephones. Since according to the ethics of the medical profession a physician cannot advertise legitimately, a certain class of medical men are prone to seek notice in newspapers by sensational announcements designed to attract to them the attention of the public. One of the subjects which several years ago served for this purpose was the alleged danger of infection from telephone mouthpieces, and since then scarcely a week has gone by without the issue of a patent on a sanitary mouthpiece attachment. Telephone users would, however, doubtless welcome an aurists' newspaper campaign that might lead to thought on the part of telephone inventors toward doing away with the cause that results in the violent "sound shocks" incident to the use of the relay system, which shocks at times are so severe as to be an actual danger to the hearing. The severity apparently has some connection with the temper of the operator, but in any event any improvement which can be made by telephone companies to eliminate this annoyance will most undoubtedly be gratefully welcomed.

THE ELECTRIC RAILWAY.

The single-phase alternating-current railway question has during the past year, and particularly during the latter months of the year, completely overshadowed all other developments in the electric traction field, and the new year opens with an electric railway situation such as has not been presented since the time of the Richmond experiments. The trials at Pittsburg, Berlin and Milan of single-phase systems have all met with a success so astonishing, that in view of the previous dubious status of alternating-current traction, the entirely unexpected outcome has had a dazing affect, and it will be some time before the probable outcome will be clearly evident. One thing, however, seems sure, and tbat is the passing of the rotary converter from a field where, indeed, it has only been tolerated *faute de mieux*. The commutator alternating-current motor is so nearly allied to the direct-current motor that it enters the lists as a competitor to the latter for all traction purposes. Even for urban service Mr. Lamme, who speaks with authority, pronounces in its favor, the disadvantage of extra weight being considered more than compensated for by the absence of rheostatic control.

Another issue brought into the field with the single-phase development is that of the trolley vs. third rail, which bodes ill for the latter, particularly in view of the Zossen experiments, which established the sufficiency of the suspended trolley system for the heaviest service. With the voltage that will be employed with the single-phase system, an ordinary street railway trolley wire would suffice in some cases where now the third rail is required to be used in order to obtain cheaply sufficient conducting cross section. The growing feeling on the part of the public against the third rail owing to its supposed "deadly" character and unreliability in winter weather, may aid in carrying the question beyond its natural limit and make it one of overhead conductors even where in heavy service this means an equivalent of a third rail supported overhead by a substantial structure. Indeed, this appears almost a necessity in the case of the rapidly coming applications of electric traction to railroad terminal service; for the use of the third rail in the terminal yard and at crossings appears to be out of the question, and a combined overhead and third-rail system would inevitably end in the survival alone of the fittest component—and a few derailments would clearly indicate the survivor.

Next in general interest to the alternating-current development has been the announcement of the New York Central of its plans for electric traction, which in outline comprise the establishment of a zone within which all through trains will be handled by electric locomotives, orders having already been given for 30 of these of 2200 hp each, and with a maximum speed capacity of 60 miles per hour, the ultimate number to be about 300; and the handling of all suburban traffic by trains operated on the multiple-unit system. The decision in favor of the direct-current system, coming as it did at a moment when the champions of alternating current felt that they had laid low the adversary, has doubtless been a source of severe disappointment to their sanguine spirit. In due time no doubt the New York Central authorities will make public the reasons for the decision in favor of direct current, and in the meantime it can readily be surmised that this may have little or no connection with the technical superiority of either of the competing systems. In fact, being limited by statute as to the time when electrical operation shall commence, and having to consider the absolute necessity of avoiding any risk of interruption of service such as is apt to be incident to a new and untried system, the decision could scarcely have been otherwise than in favor of a system with absolutely no question as to its fitness for the service required, and involving apparatus with no experimental features inviting delay. Moreover, the question of possible interchange of cars with the New York Subway System, which had already provided for direct-current operation, was no doubt a vital factor in shaping the decision. It is thus quite probable that the selection of the direct-current system depended on considerations largely or entirely of business policy, with perhaps full recognition of the probability of a change over to alternating current before many years.

WIRELESS TELEGRAPHY IN 1903.

In wireless telegraphy the sanguine expectations of a year ago cannot be said to have been realized in 1903 to any marked degree. It is true that Marconi, last January, fulfilled his promise and definitely established the feasibility of wireless communication across the Atlantic; but the effect of this achievement was discounted by the celebrated letter "S" experiment of a year before, and the abandonment of the attempt to maintain a continuous transatlantic service had its depressing influence. Perhaps, however, the greatest blows were those received at the time of the New York fall yacht races through the sad showing there made for syntonic wireless and the malicious interference set up by rival systems, which, in the eyes of the public, not only discredited all of the systems involved but, what is much worse, discredited wireless telegraphy as a whole. The truth is, the mercenary side of the wireless telegraph movement has been made so unduly prominent, the self-advertising which has accomplished the development has been so unblushing, and the squabbles between rival concerns so undignified, that the subject of wireless telegraphy as presented particularly in the newspaper press has well-nigh degenerated to a public nuisance.

To look at the brighter side of the situation, a most encouraging feature has been the practical demonstration during the year of the magnificent possibilities of wireless telegraphy for communication between ships and between ships and shore stations. Its usefulness also to communities physically isolated from the world has been demonstrated in several cases, notably in that of Santa Catalina, an island in the Pacific Ocean, 25 miles distant from Los Angeles, Cal., which, during the summer printed a newspaper having a wireless telegraph news service. In the matter of notable improvements in wireless telegraph systems, little appears to have been done in a practical way so far as recorded, though the patent offices of this country and of Europe have been sending out a constant stream of patents relating to wireless telegraphy. Prof. Lodge has at last come forward to make good his claims as the father of wireless telegraphy by presenting a system devised in collaboration with Muirhead, which has yet, however, to prove its practical merit. Braun claims to have found a method of directing to any point continuous trains of electric waves and also a method of largely increasing the energy emitted by the transmitting antenna. Hewitt has proposed a form of oscillator which seems to contain much promise. Tesla, Stone and Bull, as well as others, have made additions to the already long list of syntonic systems awaiting practical demonstration, and Fessenden and De Forest have put forth several new devices. In the purely scientific field much good work has been done in the investigation of the principles involved in wireless telegraphy in general and in the action of the fundamental details of apparatus in particular. The controversy concerning the nature of the etheric propagation of waves has continued to rage, with the advantage in the favor of those offering simple explanations based upon the work of Maxwell and Hertz, as opposed to brand new theories devised to fit the new phenomena developed.

An ominous happening of the year was the gathering at Berlin of an International Wireless Telegraph conference having for its purpose to lay down international regulations for the control of wireless telegraph communication. Aside from the baneful effect of governmental meddling with anything that does not directly relate to affairs of state, there is a particular menace in the case of a new development, which should not be trammeled at a period when every freedom of action is desirable. The part of wisdom would have been to allow a free development, and then deal with evils in the future as they arose. Our government has unfortunately become a party to this mischievous interference and it is much to the credit of England and Italy that representatives of those countries did not sign the protocol, with its hampering provisions. In this connection it is significant that in France the government has taken possession of all wireless telegraph stations, which will probably mean that instead of an inventor of a meritorious system or improvement having a free field for its development with willing capitalists to assist, he will be discouraged from proceeding owing to the bureaucratic barriers set in the way.

Curious Vacuum Tube Phenomena.

Elsewhere we print a communication from Mr. W. J. Hammer giving an account of a curious phenomenon he has noted in connection with a damaged Röntgen-ray tube. As will be seen, the tube, after having for a time been connected in an induction coil circuit, gave forth when disconnected a musical note for a considerable period with apparently no exciting cause exterior to the tube. Since the tube when removed had stored in it a considerable quantity of heat at the anode plate, the first thought is that the cause of the sound can be ascribed to some heat vibratory action, the Trevelyan "rocker" effect coming to mind in this connection. Mr. Hammer, however, appears inclined to refer the action to a condition of resonance established with respect to some etheric vibration, previous excitation of the tube having rendered it sensitive to such an etheric influence. Mr. Hammer also refers to his observation of the lighting up of a vacuum tube with apparently no exciting cause, which phenomenon has also lately been observed abroad. Both of these phenomena deserve careful study, for a complete explanation will not only be of the greatest interest *per se*, but may have an important bearing on etheric phenomena generally.

The Progress of Electric Lighting.

Electric lighting has long passed the apologetic stage of its history. It has assumed an importance so commanding that it would be scarcely worth while if it were possible to recount the details of its forward march. But they have on the whole been of about the same kind to which we have been accustomed. The student of electrotechnics as a rule finds little of a sensational character striking his attention. Yet there are dominant tendencies even if no radical changes. In the power station there has been a steady and conspicuous increase in the use of turbo-generators, which must have a salutary effect upon station economy, and now the gas engine is coming forward for recognition. We do not here propose to raise the moot point of turbines vs. engines. That will have to be fought out by the champions of the respective machines in the arena of strenuous competition. But we do wish to point out that particularly in stations of moderate size the light load conditions, always a source of anxiety, are greatly ameliorated by the introduction of turbines. Whatever the ultimate economy of the turbine may be, it undeniably has very small friction losses, and these are what count in the evil hours when there is no load to speak of and the plant must still be kept in operation. In methods of distribution there is a steadily increasing use of alternating current as might be expected, but no striking advances save in output.

The most interesting feature of the year's advance is in the direction of new illuminants. Of these the most striking is the mercury arc, which now has begun to work its way into commercial use. Its color bars it for general use in interior lighting, although improvements are promised; but this very failing makes it extraordinarily conspicuous when used for advertising purposes, a legitimate and growing branch of electric lighting. A mercury arc stops the passer-by almost as effectively as a sentinel with a fixed bayonet at charge, and its capacity for bizarre effects gives promise of continued usefulness even after the original novelty has worn off. Some very interesting experiments on its application to street lighting have been tried during the past summer, and the verdict seems upon the whole to be rather favorable, particularly where incandescents or widely spaced arcs would otherwise be used. A useful technical field has begun to develop in the application of this light to commercial photographic processes. In blue print shops and in photoengraving work the new light has already proved its usefulness, and a more recent application is in the printing rooms of photographic studios. It is found that platinum prints can be very quickly and conveniently worked off by the mercury arc, which is a great convenience in dull winter weather.

The arcs with composite electrodes of various compositions have also passed from a mere laboratory existence to tentative use outside, and while the results cannot yet be called decisive they are at least encouraging. As is probably known to our readers, some arcs of this class have given by far the highest efficiency yet attained by any artificial illuminant, even as high as four or five candle-power per watt, and the color effect is excellent. A certain tendency to smudginess seems to be the chief objection to the class in its present stage of development, but how serious this really will prove to be one can hardly say. Certainly the hope of so great efficiency will spur on experimenters to determined efforts. It is even reported that an out-and-out vacuum tube lamp is ready to pass from the experimental to the tentatively commercial stage, but this can hardly belong to the past year's record. The Nernst lamp itself, by no means now a novelty, has been quietly pushing its way into more considerable use and it really looks as if by another year the new illuminants will begin to cut some figure in the statistics of the art. Our old friends, the incandescent and the enclosed arc are still, however, doing business at the old stand and will not put up their shutters at the rumor of competition.

TESTING LARGE ALTERNATORS.

The rational design and construction of alternating-current generators depends upon the accuracy with which machines can be subjected to tests and experiments by which their properties and their behavior under different loads can be ascertained. It is not sufficient to be able to test machines after they are installed, because it is not only desirable but essential for the manufacturer to know whether the machine meets the specifications before it leaves the shop; and as usually the machines are put into service immediately after installation, the station engineer is loathe to sacrifice time and expense for tests which to him appear unnecessary and useless, being satisfied if they do the work for which they were intended. Now, it need hardly be remarked that a machine may well answer the requirements of a station without meeting the specifications according to which it was to be designed. With increased competition, it becomes incumbent upon the consulting engineer to satisfy his client and himself that the machines purchased are actually in accordance with the specifications, and that they do not evade some of the points at variance with the manufacturers' standard shop practice. It is from such considerations of the commercial importance of accurate tests on large alternators under full load conditions, and from the engineering interest of such tests, that the matter of testing large alternators is deserving of the most careful attention.

The primary points to be ascertained in the testing of alternators are the heating of the armature core, armature and field coils, and the regulation of the generators, under all possible conditions of load. Small alternating-current generators, up to 200 and 300-kw capacity, can generally readily be tested in the testing departments of the large manufacturing concerns. There are in most cases machines available of approximately the same output and voltage which can be operated as synchronous motors from the generators which are to be tested. If two machines of the same size and type are available, a test can be made on them which is a logical extension of the principle of the method of circulating power, originated by Dr. John Hopkinson in 1886 and applied to the testing of a pair of direct-current machines. While in Dr. Hopkinson's test of direct-current machines the relative position of the two armatures, which are rigidly connected, is immaterial, in circulating power between two alternators, it is this relative position of the two armatures or the two revolving fields which determines the power circulated. The greater or less difficulty in setting up two alternators and connecting them rigidly at a certain angle has limited the application of this method in practical work. Mr. William M. Mordey suggested in 1893 the feasibility of circulating power within a single machine. The Mordey alternator had a single rotating field coil, and the armature consisted of radial projecting coils, which were connected in series. By connecting more than one-half of the armature coils in series with the remaining coils, Mr. Mordey succeeded in circulating wattless current through the armature.

Applying the principle of this ingenious suggestion to the modern revolving field alternator, we have, in addition to Mordey's method of connecting armature coils in opposition, the other possibility of leaving the armature connected in series and of connecting the field coils in opposition, so that a larger number of field coils opposes a smaller number. While there is no theoretical flaw in this arrangement, the method becomes in actual practice impossible on account of the unbalanced magnetic pull produced by the armature current strengthening the fields that act as motor, and weakening the fields that act as generator. To overcome this difficulty, it has been suggested to split the revolving field into four sections, so as to distribute the disturbance uniformly over the circumference. This method seems to be but a make-shift requiring a number of connections inconvenient to make, and involves four places on the periphery of the armature at which the distribution of magnetism is different from normal. It has, moreover, the main disadvantage that the maximum induction to which the core is subjected is not the same as that in the generator when running. Another method consists in connecting the two halves of the same number of coils of the field in opposition, each half carrying the same current. There will thus be no e.m.f. generated in the armature coils, and by supplying direct current equal to the full-load current of the alternators, the current losses in the armature can be made up. In a polyphase generator tested in this manner, the direct current flowing through the armature coils produces a magnetic pull which is stationary, whereas the magnetism of the revolving field rotates with an angular velocity corresponding to the frequency of the alternator. The revolving field, therefore, with the closed exciting circuit and other closed circuits as field collars and dampers, cuts through this stationary armature field, thus leading to additional losses of a magnitude which cannot be calculated. This method, therefore, does not recommend itself, especially if we bear in mind that the accompanying conditions of armature reaction are altogether different from the actual working conditions of the generator, although it is possible by changing the connections of the armature to destroy almost completely this armature field.

Neither of the above-mentioned methods of testing large alternators permits the determination of the regulation. A modification and improvement of Mr. Mordey's method has recently been suggested by Mr. Behrend. Mr. Behrend's method consists in dividing the field of a revolving-field generator into two opposing halves, and in using different exciting currents in each half. The armature of the generator is short-circuited, and therefore no special connections have to be made excepting a lead from the common point of the field to the shaft or to a slide ring thereon. The advantage claimed for this method is its simplicity and the accuracy with which the full-load conditions are represented by artificial conditions. The experiments seem to have established the fact that the core loss in this method of testing is equal to the core loss under full load, and to the core loss on open circuit for the same terminal voltage. The method is also applicable to the determination of the regulation, as the conditions of armature reaction are almost identical with the conditions under full load at a power factor of zero Excepting the disturbances produced on a diameter by the opposing fields, there is no difference between the actual conditions and the artificial conditions for a power factor of zero. In machines having many poles, the error produced by this disturbance on a diameter is negligible, but it becomes considerable in machines in which the number of poles is less than eight. On all machines the testing of the regulation by this method is limited to the regulation for a power factor of zero.

Mr. Mordey suggested in his paper of 1893, "On Testing and Working Alternators," to supply the current in the armature from an external source. An improvement on this suggestion is found in Mr. Burnand's method, which we publish in this issue. Mr. Burnand divides the armature circuit into quarters so as to abolish the unbalanced mechanical stresses, and he forces alternating current of the same frequency as that of the generator through the armature coils. It is plain that in this manner the relative phase of the armature current in regard to the revolving field can be adjusted. The method, however, does not seem to be free from defects. In the first place, the number of field disturbances is again increased to four, and in the second place, the method is rather difficult to carry out in the testing room. It must be remembered that most commercial alternating-current generators are polyphase machines, and the splitting of the armature coils is a rather inconvenient operation. The field disturbances must affect the determination of the regulation, and, therefore, this method appears to have no advantage over that of Mr. Behrend, excepting that there are four field disturbances in Mr. Burnand's method, against two in that of Mr. Behrend. With the advent of the steam turbine generator, the number of poles in large units will be greatly reduced, and while 60-cycle engine type generators for 3,000 kw and 75 revolutions have 96 poles, the coming turbine generator has for the same output only 12 poles. For 25 cycles an engine type generator of this capacity has 40 poles, while a turbine generator has only 4 or 6 poles. The methods of test, therefore, which have been developed for large alternators of the slow-speed kind, will have to be adapted to the high-speed generator, and new methods originated which permit the satisfactory testing of high-speed alternators under full-load conditions. Meanwhile, all the various methods proposed will be put to test and the method which survives will finally be recognized as the fittest for the manifold conditions that must be satisfied.

The International Electrical Congress of St. Louis This Year.

Now that we open the year 1904, the prospect of the International Electrical Congress enlarges and takes definite outline. The evidences are gathering to show that the success of the Congress will be marked. The number who have in writing already accepted membership in the Congress is over eight hundred. European engineers are now being invited to join. Until quite recently the invitations to join the Congress have been restricted to Americans, in order to make sure that a fair start could be obtained before asking foreigners to participate. It is not to be expected that a very large number of foreigners will attend the St. Louis Exposition or the International Congress, but it is quite likely that a number of European electricians will naturally desire to join the Congress in order subsequently to secure copies of the *Transactions,* since these *Transactions* already promise to have great electrotechnical value, and the expense of obtaining them independently at a later date is naturally liable to be greater than by original adherence to the Congress.

Some of the best electricians in Europe have already promised to contribute papers to the sections in September, and all of the papers to be read are to be by special invitation. The result of this policy of the Committee of Organization should be to produce at least as fine a set of papers, discussions and transactions for electricity as the Physical Congress of Paris in 1900, whose volumes have world-wide recognition as marking the universal knowledge and status of each branch of physics at the end of the nineteenth century. A number of prominent American writers have also promised to contribute papers, so that the representation that America can offer in the world's electrical knowledge and applications is not likely to be deficient. The State Department at Washington has also promised to espouse the cause of the Congress, and is believed already to have taken action on the invitations of foreign delegates.

There now remains to arrange the details of the plans of co-operation with electrical organizations who may desire to participate in the Congress, collectively as societies or associations, as well as individually through their respective members. Notably this is the case with the American Institute of Electrical Engineers whose membership has a large representation in the Congress, and whose president is the chairman of the Executive Committee of the Committee of Organization of the Congress. Ten members of the Board of Directors of the Institute are also officially connected with the Congress. It is hoped that the Institute, which is interested in the work of most of the Congress sections, may take an official representation in the Congress and participate in the proceedings. Invitations are being forwarded to various other physical and electrotechnical societies, asking them to join in the official representation and participation at St. Louis. It is, therefore, to be hoped that the proceedings of the Congress will represent the best available papers, and also the best available work of individuals and of societies, scientific, electrochemical, electrical engineering and electrotherapeutic, all over the world. Ample accommodation has been promised within the precinct of the Exposition for the Congress. In fact, the accommodation offered will not only be ample for all the Congress sections working simultaneously, but also for such other electrical organizations as may desire to hold a convention in St. Louis simultaneously with the Congress.

The Progress of Electrical Theory During 1903.

No noteworthy discovery in electrical theory has received prominent notice during the past year, but steady progress in electrical science has been made. In particular, the electronic theory has steadily advanced. That is to say, the theory is gaining ground steadily that electricity is indissolubly connected with the component parts of an atom of matter; or, what may be the same thing, that atoms are composed of electricity, or are disturbances of ether corresponding to minute electric charges. Every year that passes extends the scope of the science of electricity, which is only another way of expressing the fact that the various sciences are approaching unification. Optics became a department of electricity when, by the labors of Maxwell and of Hertz, the electromagnetic theory of light was established. Similarly, there is now laid in the electronic hypothesis a basis for an electrical theory of matter in general, and of dynamics in particular.

It is by no means yet clear that the inertia of matter, the inertia of a billiard ball, for example, is due to the self-induction of electricity in the ball, and the opposition which self-induction sets up to an electric current or moving electric charge. But it now seems to be clear that there are large aggregate electric charges bound up in some intro-molecular way with the ivory or composition, of which the billiard ball is formed. It is also known that such electric charges must resist being moved or stopped, by the self-induction law, according to the same law as mechanical inertia; that is to say, according to the second differential of the distance with respect to time; or, in ordinary language, in proportion to the acceleration. There seems, therefore, to be no escape from the proposition that at least a part of the inertia displayed by a billiard ball is due to self-induction. The real question is whether there is enough electricity, on the whole, in the matter of a billiard ball, to account for all of the inertia. An electrified pith ball, for instance, is supposed to have a small amount of extra inertia, due to its electrification; but so little extra, that it has never been made evident. The total charge stowed away molecularly in a billiard ball must be immense, in order to account for all of the inertia electrically. If all the atoms carry the same charges that they carry in electrolytic processes, the electrical share of the inertia of a billiard ball would seem to be very minute. But if, according to the electronic theory, there may be numerous electrolytic atomic charges stowed away in an atom, then it would be possible to account for all of the inertia by self-induction.

The suggestion is strong, therefore, that dynamics is now a department of electricity; or that electricity is a department of dynamics; or that there is no longer any fundamental division of science into electricity and into dynamics; but that both are branches of a yet more fundamental knowledge, bringing to mind the time-honored remark of the French King to his son departing to ascend the throne of Spain: "The Pyrenees no longer exist." The signs of the times are that in this way each science will extend over the borders of its neighbors, until, when it has conquered them all, it will have destroyed itself, and all the sciences will be one and the same. This tendency to merging unification and desectionalizing is steadily pervading every human interest.

RECENT ELECTROCHEMICAL DEVELOPMENTS.

Under this title we have presented weekly concise analyses of current electrochemical patents, which latter collectively may be said to represent the only available authoritative literature on the newest developments in this branch. On the other hand, in electrochemistry—as in other departments of applied science—patent specifications are apt to represent rather the inventor's hopes than real accomplishments. A summary review of the present actual condition of the electrochemical industries may, therefore, not be without interest at the present time. The year 1903 has not witnessed any developments on remarkably novel lines, yet there has been a very considerable activity, and conscientious and persevering work along certain lines has resulted in some new additions to the art and considerable improvement in some of the established branches. Thus in electric furnace work, the apparently very simple reaction between silica and carbon in a furnace became with Acheson the starting point for the gradual development of the industries of carborundum, artificial graphite and more recently "siloxicon." The principal point established is that the decisive factor determining the product of the reaction is the temperature. While at the time of the advent of the electric furnace the desideratum was the production of the highest possible temperature, now the end is so to design a furnace that the temperature can be held uniform and can be exactly regulated within given limits. Acheson's siloxicon furnace and Tone's silicon furnace illustrate this development during the past year.

In one special line the electric furnace has made important advances, especially in Europe, and that is the metallurgy of iron and steel. It is true that we have here but the beginning of a development, but it is a branch which promises to become of great importance. At present ferro-alloys and special steels are commercially made in the electric furnace, and there is a greatly increased interest in the electric furnace metallurgy of rare metals. It is in the manufacture of the most expensive special steels that electric furnace methods appear to have the best prospect, and it seems probable that in a few years "crucible steels" will no longer be made in crucibles. One of the chief advantages of the electric method is easy control and cleanliness, there being no contamination from the fuel gases. In this connection it is interesting to note how electrochemical inventors strive to avoid contamination from the presence of carbon electrodes. Heroult and Keller use carbon electrodes which do not reach into the fused metallic mass, an arc jumping from the carbon to the mass and another arc back from the mass to the other carbon—a slag at the top of the mass protecting the fused steel from contamination. Kjellin is still more radical, since he dispenses any electrodes entirely, his charge forming the secondary of a transformer. The developments in this line are of particular interest to the electrical engineer owing to the bearing on the production of steel with special magnetic properties.

While the calcium carbide industry continues in a satisfactory state, its expansion depends upon increased uses of acetylene, and in this the development is somewhat slow. In this connection we may recall a remark of the late Luther Stieringer, who expressed the hope that, owing to the beauty of its light, he might have an opportunity to light an exposition with acetylene. The aluminum industry being now relieved of the uncertainty of status existing during the long patent litigation recently closed, is now in a position to strike out more vigorously in new directions. The use of aluminum for electric conductors increased largely during the past year, and its employment as a reducing agent in metallurgy for producing very high temperatures locally and almost instantaneously, has been developed by Goldschmidt into a new branch of engineering, aluminothermics. The electrolytic production of metallic sodium and potassium continues to increase annually, and their use is largely extending in the cyanide process of recovering gold. In this country the precipitation of gold from cyanide solutions is still mostly done by zinc shavings, but the electrolytic method continues predominant in South Africa. The production of caustic soda and bleaching powder by electrolysis of sodium chloride has become a very extensive electrochemical industry and in this field the new electrochemical methods have attacked, and in some cases finally conquered, old and firmly-established chemical industries. The variety of this electrochemical method is well illustrated by the fact that three essentially different processes are commercially successful in the same field in this country, namely, the Castner-Kellner mercury cathode process, the Acker process for the electrolysis of fused salt, and the diaphragm cell process. Unfortunately, the market is utterly demoralized at present, and the hope for better conditions rests in a mutual understanding concerning selling prices now said to be under consideration by the manufacturers.

An interesting development in the New England States is the installation by the larger paper and pulp mills of their own electrolytic plants for making the bleach required in their works. The general use of apparatus for making hypochlorites or bleaching liquors, while increasing in Europe, has not made much headway in this country, although it should here have a good future in bleaching finer linens and in laundries. In refining copper this country easily ranks first, and the industry is in prosperous condition. The United States now produces 85 per cent. of all the refined copper of the world. A very promising beginning in the refining of lead has been made in the Betts process, and gold is being electrolytically refined in the Philadelphia Mint. There is little doing commercially in the electrolytic production of metals from their ores, although the Browne process, which has been successfully used for several years in Cleveland for separating copper and nickel from the Sudbury ores, will be employed on a larger scale by the International Nickel Company upon the completion of a new plant now under way. In electroplating—the oldest branch of electrochemical engineering—

there is to be observed a pronounced tendency to get rid of the old rule of thumb, which has afflicted this particular industry to an extent that greatly handicapped its progress.

Perhaps the most interesting development in electrochemistry has been with respect to processes involving electric discharges through gases. The production of ozone from air and the use of ozone for sterilizing water have proven successful in Europe; whether they will obtain commercial importance in this country is simply a matter of dollars and cents, but the technical difficulties may be considered to have been overcome. The most promising development in this line is, however, the Bradley process for the fixation of atmospheric nitrogen, although no new developments have been recorded concerning it during the last year. In the battery field there has been again great activity, though confined principally to the patent office; and as in the past, but few of the inventions in this line there recorded give promise of any future. The lead accumulator's position seems assured as an auxiliary for light and power purposes. On the other hand, the future of the belated Edison nickel-iron accumulator seems very bright for automobile purposes. The old dream of electrochemical inventors of a carbon cell that will revolutionize the generation of electrical energy still remains a beautiful dream, and it is with regret that we have to state that there are no signs yet that it will soon be realized in practice. If aspiring inventors in this line would, before commencing to invent, make themselves thoroughly acquainted with the role that thermodynamics pl ys in electrochemical action, much waste of effort would be spared—and no inconsiderable sensational copy lost to the newspaper press.

A Year of Extreme Radioactivity.

No branch of physical science has, in the last twelve-month, been prosecuted—we had nearly said persecuted—with so much vigor as the investigation of the curious phenomena of radioactivity. The greatest interest has naturally centered about the remarkable discovery of Mde. Curie that radium salts seem able normally to maintain a temperature slightly above their surroundings—that is, they give out heat spontaneously to a very perceptible amount—and several of the year's researches follow directly along this line. As a preliminary to any discussion of this curious fact, it is well to remind the reader that in nearly all the popular articles and many scientific ones, radium is a word used to denote not the metal of that name, but its chloride or bromide, generally the latter. In a similar slipshod fashion the photographer sometimes refers to the silver in an emulsion, meaning thereby the bromide or chloride of silver. Radium, the metal, is as yet unknown, although a pretty good guess may be made as to its more general properties, but whether it is itself radioactive remains to be seen. So when the statement is made that radium decomposes or gives off emanations, or rays, it is wholesome to remember that the bromide of radium, generally quite impure, is the substance having these properties. As to the amount and character of the impurities referred to, it would be unwise to hazard a guess. Madame Curie, like her distinguished husband, is far more cautious and conservative in statements about radium than those whose knowledge is derived merely from a few decigrams of the stuff in a sealed tube. Her study of the atomic weight of radium showed steadily increasing values, for preparations of increasing purity up to her last figuring 225. Some rather reliable spectroscopic evidence indicates an atomic weight exceeding 250, so there is good reason to suspect that even the purest radium bromide yet obtained is by no means pure in the chemical sense, while the best commercial preparations are of much lower quality.

The spontaneous evolution of heat from radium is far from having a satisfactory explanation. The hastily jumped-at conclusion that radium breaks up into electrons with evolution of energy in enormous amounts, is hardly in accord with the physical and chemical stability shown by the spectroscope, and in the preparation of the substance. We fancy that as time goes on less and less will be heard of computations regarding the stored energy of radium in kilowatt-hours per milligram, and of the spontaneous formation of radium out of nothing in particular required to account for its continued existence. The hypothesis of Madame Curie, reinforced by Kelvin, that radium receives radiant energy of a kind usually neglected and gives it out as heat, is much more nearly in line with the ordinary facts of physics, but must wait for its proof until various problems in obscure radiations have been solved. The striking and beautiful work of M. Blondlot on the N-rays bids fair to throw much light on this phase of the subject, since these rays present many of the attributes of radioactive emanations and yet obey the ordinary laws of radiant energy, being reflected, refracted and polarized in the usual manner. The recent announcement that radium gives off an emanation that acts like a heavy gas (or is one!) which later spontaneously decomposes with probable evolution of heat and certain evolution of helium is, from a purely scientific standpoint, of much greater importance than even the thermal anomaly just discussed. The first chemical step toward the comprehension of an unknown substance is its resolution into known products of decomposition. Of course, in the case before us the next question to be asked is with what the resultant helium was combined to form the heavy gaseous "emanation." We do not like this word emanation—it smacks of the days of "caloric" and "dephlogisticated air." If impure radium bromide gives off a heavy, unstable gas, why not state the fact in so many words? The immediate inference, that radium must be regarded as a condensation of helium, is immensely important—if true.

The first step toward a proof would be to show that the heavy gas is a condensation and not a compound of helium. The spectrum of this gas is reported as of unknown character, but should, on investigation, show its kinship to helium or to something else, and thus answer the question one way or the other. Certainly the present evidence is a very slender foundation for the announcement of the transmutation of elements as an accomplished fact, although we believe that at least one stock company for modern alchemy is already being exploited on the strength of it. Unhappily, radium is extremely scarce and separated only with great expense, so that it is at present almost impossible to study it by ordinary chemical methods. Possibly pending a better source of radium a concentration of attention on thorium, which is far more accessible and has very similar properties, would tend to the advancing of our knowledge of radioactive phenomena. Radioactivity as such, now that attention has been called to it, seems to be a rather common thing, so common that it is hazardous to conclude from its appearance that any of the well-known radioactive substances are concerned in the phenomenon. It may even turn out that one should think of radioactivity as merely a quality rather than the result of the presence of an unusual substance. Experiments with the metals which furnish radioactive salts are likely to be of particular value in settling questions of this sort. Experiments like those of Bàskerville, who found that radium was greatly increased in activity by mixture with a powdered natural silicate of zinc, are also likely to be fruitful. Radioactive substances have been studied too exclusively from the electrical standpoint, and the important advances of the past year have been notable for the wholesome tendency to seek other kinds of evidence and to study the phenomena by the light of other branches of scientific research. The facts are now being accumulated rapidly, and we hope before another year is passed that generalizations of some value will be possible. And we are disposed to think that the whole subject will be greatly simplified when the phenomena are seen in their true relations.

The Government Printing Office—The Electrical Equipment of the Largest Printing Office in the World.—I.

INTRODUCTORY.

NOT only with respect to external dimensions and floor space, but in regard also to number of employees and extent of output, the Government Printing Office at Washington, D. C., is fully entitled to claim the distinction of being the largest printing office in the world. The American love of mere bigness is gratified in every figure that one can cite about it, while in equal degree the American passion for doing everything by machinery and mechanical appliances is manifested there in every respect save one, namely, the use of typesetting machines—but that is another story. To the visiting electrical engineer it is more than gratifying to note how with remarkable boldness, but with corresponding judgment and discretion, electricity has been called upon to discharge all the vital functions of light and power, as well as to furnish heat in novel and convenient manner. The display of the flexibility and resourcefulness of electricity in all parts of the plant is, indeed, a fascinating study. The work here done is done in such a way that he of all men whose heart it would most have rejoiced was at once this country's typical printer and pioneer master electrician—Benjamin Franklin himself.

Standing in a section of the city that is otherwise devoid of large buildings, the Office looms up in dominating proportions that gain by the clear vistas, and its huge red pile is a notable landmark of the National Capital. Many of the public offices in Washington suggest by their exterior a bureaucratic nature and a devotion to clerical work; but whether by design or not, the Printing Office wears a utilitarian air that well befits it without marring its quiet and unostentatious dignity of aspect. The building of red brick, with terra cotta and sandstone trimming, has a front of 175 ft. on North Capitol Street and a depth of 408 ft. on G Street, and has a height of seven stories, exclusive of deep basement and loft. It is nearly a hollow square, as shown by one of the floor plans in this article, so that the interior spaces of the vast area get their share of outside light. All told, there is not less than eight acres of floor space, and of this six acres is available for actual working purposes. The interior court is 30 ft. wide and 167 ft. long, and the power house at the northwest corner completes the rectangle. The framework is of steel, over 12,000,000 pounds having been employed, and the stories all 16 ft. apart from floor to floor, with an approximate distance of 12 ft. from center to center of the window spaces. The iron and steel structural work is covered chiefly with fire brick, and the substratum of all the floors is brick and concrete. Upon this in working areas is generally laid 1¼-in. maple flooring; and there is 210,000 sq. ft. of wood block floor, 300,000 sq. ft. of cement floor, and 15,000 sq. ft. of tile and mosaic. The main entrance on North Capitol Street is of richly ornamental character in gold, tile, mosaic and marble panelings and stairways, with a pedestal at the main stair flight to be occupied in all probability by a heroic bust of Franklin. It is at this point that interior decoration is concentrated, and but a few steps away everything is sternly and severely strong, for use, not show. There are numerous wide halls and stairways throughout the building, all strictly fire-proof, in steel, slate, etc., and there are over a dozen elevators which also afford means of entrance and exit for the 4,000 employees under Public Printer Palmer's administration, as well as for the vast quantities of material handled. It is quite needless to emphasize, even in passing, the necessity even on an ordinary basis, for careful and elaborate plans of wiring in advance; but it must be borne in mind that almost on every floor of this solid, rock-ribbed construction special circuits have had to be run to some piece of apparatus or line of machines. Hence, for complexity of distribution, it would be hard to match the building under consideration, whose daily consumption of current compares with that of many a large central station system.

FIG. 1.—VIEW OF THE EXTERIOR OF THE GOVERNMENT PRINTING OFFICE, WASHINGTON, D. C.

In dealing with an institution of the scope and character of the Government Printing Office, it is impossible to bring to notice, and undesirable to do so, many features of great interest; and the present article is necessarily restricted to topics falling within the purview of this journal. But in order that the reader should understand what electricity is called upon to do, certain items must be noted before a detailed description of the plant is taken up. The data are perhaps unrelated, but all bear upon the subject. At first glance the annual expenditure of $6,500,000 annually here on government printing may seem fabulous, but a brief analysis of the work done and stock carried by the Office reveals conditions and capacity that attest the extraordinary practical importance of the plant as one of the elements of national diffusion of intelligence. When we find over 4,000 employees, to say nothing of visitors and business callers, we appreciate the necessity for the 8 electric passenger elevators, all of which could handle the whole crowd from the first to the top floor every twenty minutes. When we learn that the annual consumption of paper, for book printing alone, is 100,000 reams flat, and 110,000 reams in rolls; that 3,000,000 sheets of Bristol and cardboard are used; that 1,700 reams of cover paper, 35,000 reams of writing paper, 1,700 reams of typewriter paper, 4,700 reams of manila and tissue paper, and 10,000 reams of coated book paper are used up each year—then we grasp the utility of the five big freight elevators, all electric. One of these at the sidewalk, to carry paper from basement to first floor, will lift 6,000 pounds 100 ft. a minute. Another of the freight elevators has a capacity of 10,000 pounds 150 ft. a minute. The other three will each handle 5,000 pounds 350 ft. a minute. It will be seen at once that the Office in elevators alone has the capacity of a good-sized electric railway for passengers and freight, and needs it all.

Looked at from the other standpoint of output, and disregarding the other items of work within the Office as a self-sufficient organism, it will be seen that the data are again extraordinary. A consumption of 30 to 35 tons of paper daily on the presses all run by electric motors tells the story in one way. The fact that 700,000 volumes of departmental reports are carried in store, ready for distribution, tells it in another, for each volume has to be composed, proofread, printed, folded, bound, labeled and followed through to storage or to the proper depositories and channels of distribution. Then there are such incidental items as the *Congressional Record,* with a daily circulation of 23,000, while Congress sits, a single issue having reached 192 pages. The edition hereafter will run much higher, but the last copy must be off the press to catch the morning mail trains around 5.30 A.M. Such regular work is intensified by sudden demands for special printing required by Congress, to meet which all the resources of the Office are strained and the electrical plant is driven to its limit. The issuance of the famous report on the blowing up of the *Maine* is an instance. Consisting of 298 pages of text, 24 full-page engravings, and one lithograph in colors, and the manuscript being received at 6.30 P.M. one day, a copy lay on every desk in the Senate and House next morning at 10 A.M. As to the speeches of members of Congress printed in pamphlet form from the *Record,* they run into the tons and the millions. Moreover, there are other daily issues that must come out on time, hot from the press, as any "yellow," and even the United States Supreme Court has its daily with a select circulation of some three-score copies. Bills again use up a tremendous lot of paper and ink and electricity, for the passion to regulate everybody else by legislation never wanes, as evidenced by the ghastly fact that in last Congress there were printed 8,025 Senate bills and resolutions and 18,420 from the House, of which 1,384 became law, when at least one copy to be filed with the Secretary of State had to be printed by special motor-driven presses, on parchment. Every week the electrical field is brought into close touch with the work of the Office by the issuance from it of the electrical patents just out of the United States Patent Office and the weekly number of that Liebig's extract of invention, the *Patent Office Gazette;* while once and again come other reminders in the shape of Census Bulletins on street railways, electric lighting, etc. The Printing Office has had at one time 20 tons of fine type and rule work standing for the United States Census Office; while its ability to respond to calls for new editions, etc., is shown by its storage vaults under the sidewalks, with a capacity already pretty well occupied in the new building, for 2,000,000 electrotype plates, every one of which has been, or will be, made by the Office's own electrical equipment. Facts of this kind could be piled one on the other, column after column, but the data now quoted will probably suffice to illustrate at once the scope and quantity of the work accomplished as well as the absolute confidence placed in electricity as the actuating medium.

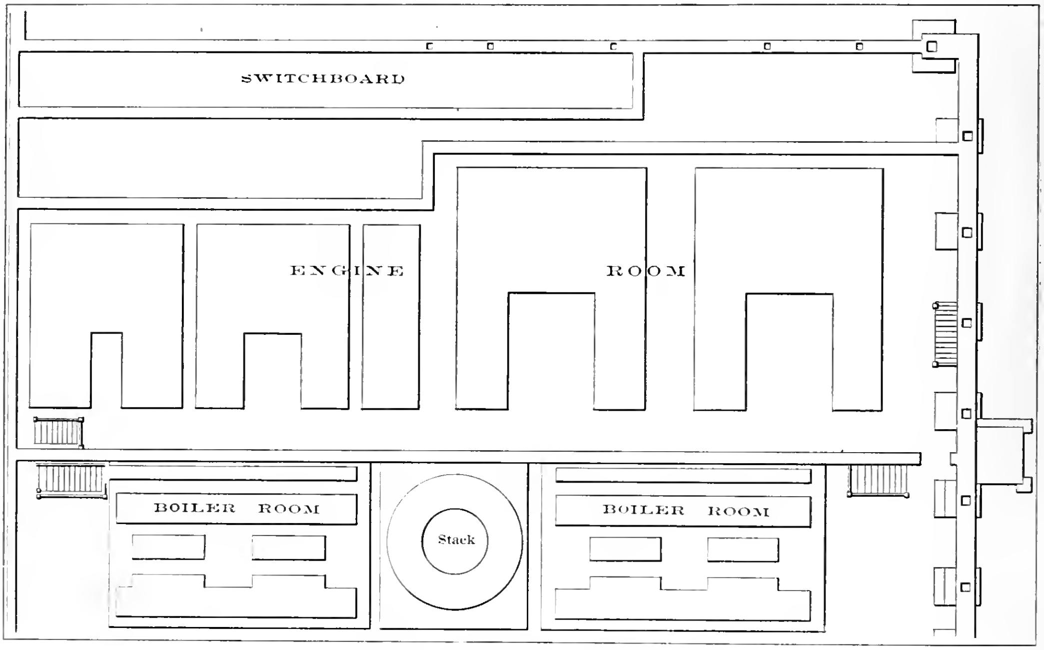

Fig. 2.—Plan of Engine Room, Dynamo Room, etc.

POWER PLANT.

The power plant of the Government Printing Office constitutes, as already noted, a part of the interior quadrangle, being flanked by the old and new wings, which together form the present establishment. The power house is a brick building 112 x 134 ft. in plan, and is divided longitudinally between the engine and dynamo room and the boiler room, as indicated by one of the line engravings herewith, which shows the foundation plans of the two sections and of the stack. While in a sense of evolutional growth, the plant is essentially a well-planned unit as it stands. The first plant was put in some years ago in the old building, and proving successful, but outgrown, it was abandoned and a new power house was erected. The work of moving was a difficult undertaking, as it had to be done without interfering with the operation of the plant. It was effected, however, very smoothly by Mr. W. H. Tapley, the chief electrician and electrical engineer, and Mr. H. K. Collins, the chief engineer. The plant then installed was adequate to the requirements of the old Office and consisted of one 300-kw, 125-volt generator, running at 150 r.p.m., and one 125-kw generator of same voltage and speed, both dynamos being built by the Crocker-Wheeler Company, of Ampere, N. J., and both engines by the E. P. Allis Company, of Milwaukee. When extensions to take care of the new office came up, one of the most important problems was that of continuing the lower voltage or of adopting 250 volts. It was finally decided to adhere to the old pressure of 125 volts, and the additional contract was placed for two additional Crocker-Wheeler generators of 600-kw capacity, 100 r.p.m., and two Allis engines of corresponding

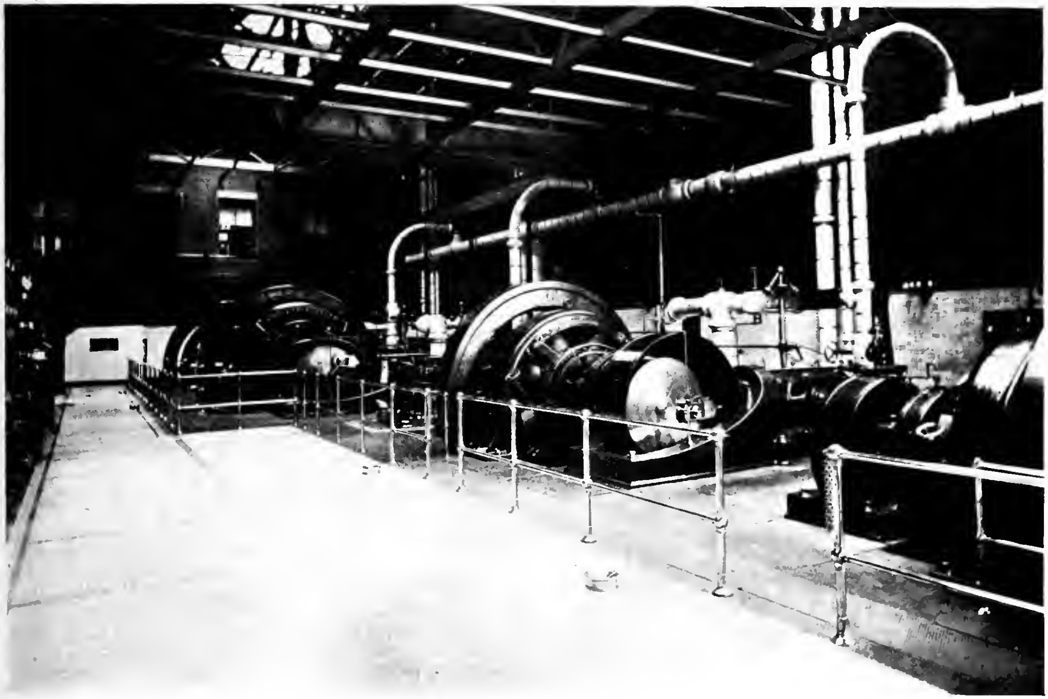

FIG. 3.—GENERAL VIEW OF ENGINE AND DYNAMO ROOM.

capacity. These generators, of the multipolar type, were required to be overcompounded 5 per cent. at full load, with series coils so proportioned as to overcompound by regular equal increments proportional to the output between one-quarter and full load, with a maximum variation at generator terminals not exceeding 1½ volts when running within 1½ per cent. of standard speed; this overcompounding being reduced in the regular operation of the plant to 3 per cent. by the use of German silver shunts in the service fields. The compounding is also so arranged as to permit the generator after having "built up" and when running at standard voltage, being thrown in circuit without taking any of the load or being reversed; and to run thus indefinitely, if necessary. The dynamos have a guaranteed efficiency of 94 per cent. at full load, and will withstand an overload of 25 per cent. continuously for four hours, as well as momentary overloads of 50 per cent. At 25 per cent. overload, the efficiency is 93½ per cent.

Special features of the machines are the internally-flanged frame, giving a very smooth outside appearance and great rigidity. The brush rigging consists of a circular cast-iron ring held in place by supports bolted to the frame and holding the brush [illegible]. The brush holders themselves secure the brushes by means of a [illegible] side of which is held tightly against the brush. Four sets of copper leaves carry the current from the brush box to the arm, and their position is such that the movement of the brush on the commutator is always radial. Hence, there is no necessity of changing the seating after the brush is once worn to place. The spiral spring with the thumbscrew attachment secures the proper brush tension, and the copper leaves, carrying all the current, relieve the spring of any such duty. In spite of the great capacity of the apparatus, its compactness is also a notable feature. The large air-gap tends to reduce field distortion and consequent sparking under heavy loads. The units have been in operation for several months and, as usual, they run very quietly and without heating.

The four Allis engines furnished by the Allis-Chalmers Company are all cross compound direct-connected, the smaller ones being respectively 10 x 19 x 30 and 16 x 30 x 30; while the two new larger ones are of the same size, namely, 22 x 44 x 42. The small machines are arranged to run 150 r.p.m., and are supplied with steam at 125 pounds pressure, exhausting into Knowles barometric condensers. The engines are fitted with the regular Reynolds Corliss automatic valve gear, and have separate eccentrics for operating the steam and exhaust valves on the low-pressure side. The regulator is of the standard heavy weighted type, operating the cut-off cams of both engines, and having in conjunction a safety stop, which guards the engine in case of the breakage of the governor belt. A variation of less than 2 per cent. is guaranteed between no load and full load.

In addition to the governor belt safety stop, there is provided an extra governor which operates a stop valve placed above the throttle valve in the steam pipe, so that if the engine reaches a speed of five revolutions above normal, this valve is released and closes, thus shutting off all steam to the cylinder. In view of this relatively high rotative speed, the steam passages are liberally large, so that the velocities are kept low, and all wearing parts are also amply large for smooth and satisfactory operation.

The engines are fitted with metallic packing, and are adequately provided with oil guards and fittings for due lubrication and cleanly operation. One of the requirements of the contract was a 30-day continuous operation without undue heating or wear of any part. A steam guarantee of 15½ pounds of water per indicated horse-power was also given when operating with steam of 125 pounds and a vacuum of 26 in. The normal rating of these two larger engines is 800 hp and of the two smaller ones 450 and 250 hp, respectively, so that the ratios to the dynamos are 1 to 1, 1.11 to 1 and 1.18 to 1, but it does not appear that the high rotative speeds of the small engines has militated against them in any way.

As will be noted by the engravings, all these handsome generator units are generously spaced with plenty of elbow room, within the brass rail that divides them off from the rest of the spacious hall and from the switchboard, a view of all being commanded by a broad gallery from which stairs run down to the main floor. Each generating unit foundation contains an opening by which an attendant can reach the anchor bearing plate and end of the bolt, and, indeed, the clear basement space affords freest access all around the foundations, which, by the way, are solid to a degree and remarkably free from tremor. The receivers between the cylinders of the engines are in the basement, but the piping connections of the low-pressure cylinders are, as will be noted, largely above the engine floor. The exhaust pipe between the high-pressure cylinder and receiver is also in the basement, but rises into the engine room, where the passage of steam to the low-pressure cylinder is controlled. The live steam connection to the low-pressure cylinder leads into this pipe and has a stop and a reducing valve. The exhaust pipe line from each engine runs in the basement to the partition wall and rises in each case to an independent condenser above the roof, being fitted with a back pressure relief valve for the escape of steam in case the corresponding condenser should be out of commission. The Knowles syphon condenser is used, with 27 in. vacuum, and, as seen, there are thus three lines of piping that rise against the wall at the rear of each engine, one the exhaust, one for the injection water from the District supply lifted to the condensers by the supply pressure, and one for the discharge from the condenser, going to a hot well tank in the basement, whence it is pumped to six attic tanks for house and toilet flushing, an aggregate capacity of some 4,000 gallons being thus furnished.

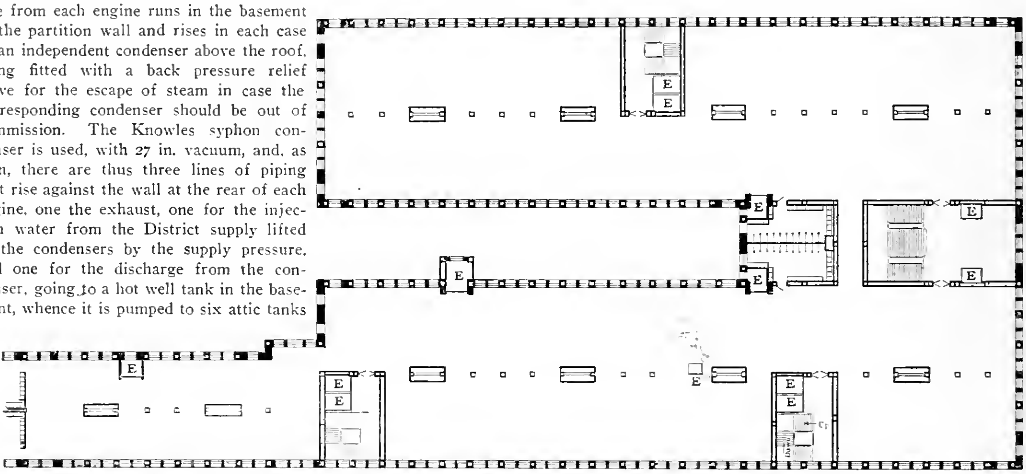

Fig. 4.—Typical Plan of Floor in New Building for Government Printing Office. E. Elevators.

The oiling system for the generating plant consists of overhead reservoir tanks, pipes to and from journals and bearings, a filter for return oil and a centrifugal pump for lifting it back again. The Warden filter is located in the engine room basement and empties into two tanks connected together, in one of which submerged is the pump driven by a direct-connected 3-hp Northern Electric motor. This pump delivers to three overhead tanks in the boiler room, with a capacity of 500 gallons. The oiler piping system is of brass. The steam piping throughout is protected by Keasbey & Mattison magnesia sectional covering, and its appearance in the engine room where so much of it is in sight is greatly enhanced by the white canvas brass-banded jackets.

BOILER ROOM.

Before passing to consider other details of the dynamo room, note must be made here of the features of the boiler plant, which is of somewhat unusual type in this class of work, and which comprises eight 300-hp marine type Scotch boilers furnished by I. P. Morris & Co., of Philadelphia. These boilers were built for a working pressure of 150 pounds, under the direction of United States supervising inspectors for steam boilers, and steam is supplied through an 8-in. dry pipe and nozzle to the main line of steam pipes. The plant is herewith illustrated, Fig. 8.

Each boiler is 12 ft. mean diameter, 13 ft. long from outside to outside of heads and 14 ft. 1 in. over all, with two 45-in. inside diameter Morrison furnaces, each 9 ft. 6 9/16 in. long with one combustion chamber common to the two furnaces, and containing 168 3-in. diameter standard tubes and 68 3-in. diameter No. 6 B.W.G. in thickness, screwed end stay tubes, the length of all tubes being 9 ft. 2 in. between tube plates. The thickness of material is as follows: Shell, 1 3/32 in.; heads, 15/16 in.; combustion chamber, sides and top, ⅝ in.; combustion chamber, back, 9/16 in.; combustion chamber, front or tube sheet, ⅝ in.; furnaces, 9/16 in. The longitudinal seams are double butt-strapped and triple-riveted with 1 3/16-in. steel rivets and 1¼-in. drilled holes, which gives a percentage for the strength of plate of 85.04 and for rivets 96.06.

Using the percentage of plate, which is 85, and figuring the tensile strength at 55,000 pounds per square inch, we get a factor of safety as follows:

$$\frac{1\ 3/32'' \times 0.85 \times 55{,}000}{72'' \times 150} = 4.734,$$

factor of safety at 150 pounds pressure per square inch.

The circumferential seams are double-riveted with 1¼-in. drilled holes and 1 3/16-in. rivets. The boiler heads are braced with twelve 2½-in. diameter boiler brace steel braces between and below the tubes. The top of the combustion chamber is braced with fourteen double-crown bars, spaced 7 in. center to center, each having four 1⅜-in. diameter steel studs for carrying the sheet. The back and sides of the combustion chamber are braced with 1⅜-in. diameter screw-stays. Over the front of each boiler and supported on steel framework is an economizer 85½ in. mean diameter, 8 ft. 10½ in. between tube plates, which contains 306 3-in. diameter tubes. The bottom of this economizer is connected to the smoke box of the boiler, so that the gases when leaving the boiler pass through the economizer and thence to the smokestack. The system of feeding these boilers is to combine the feed water with the dead water which is taken from the extreme bottom of the boiler, and pump this water into the bottom of the economizer; taking it from the top at a point low enough below the surface of the water to insure that no scum will go with it and then delivering the water to the boiler. The object of combining the dead water from the bottom of the boiler with the feed water is, first, to force a circulation in the boiler, and, second, to assist in heating the feed water so that it will not make the tubes in the economizer sweat, as it is likely to do if the feed water is low in temperature. Each boiler is connected to the main smoke flue by an oval connection 4 ft. x 2 ft. 6 in. The large diameter of the smoke flue for the eight boilers is 6 ft. 3½ in. The boilers are equipped with McClave shaking grates 7 ft. 2½ in. long.

The boilers are set in two rows facing each other across an aisle 21 ft. wide, and the boiler room is itself 53 ft. 2 in. wide. The floor is vitrified brick and the brick walls are whitewashed. A system

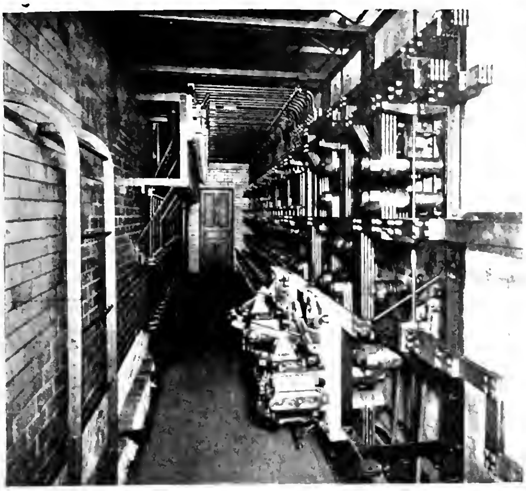

FIG. 5.—BACK OF SWITCHBOARD.

FIG. 6.—PUMPING OUTFIT.

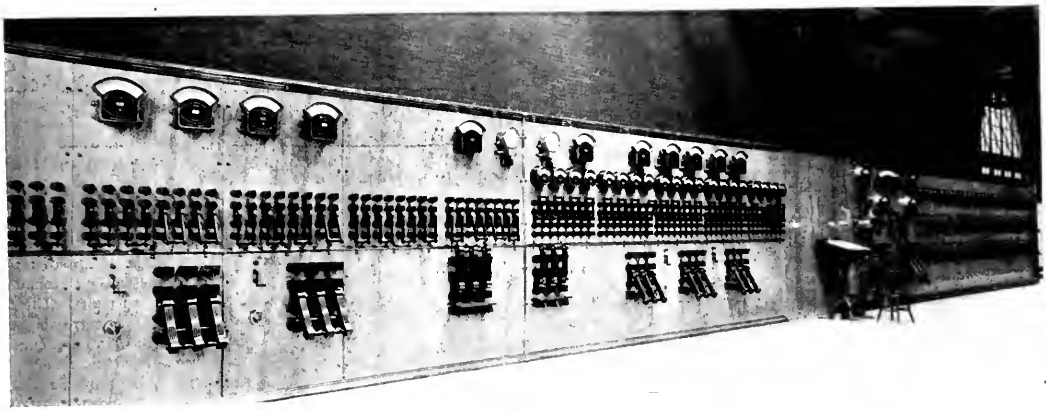

FIG. 7.—GENERAL VIEW OF SWITCHBOARD.

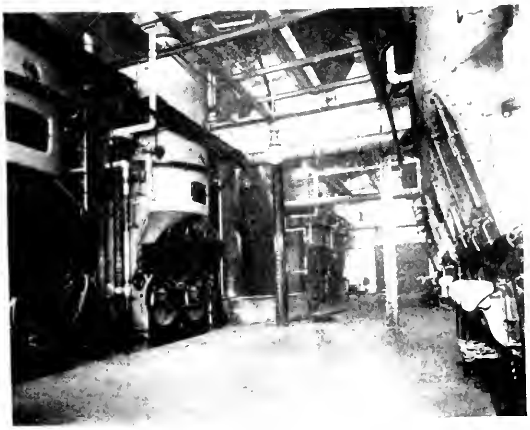

FIG. 8.—BOILER ROOM.

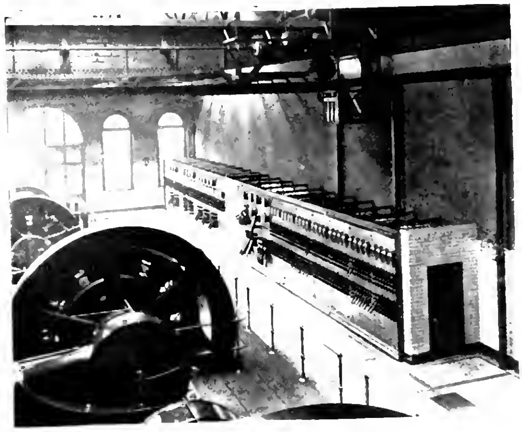

FIG. 9.—ELECTRIC CRANE, DYNAMO ROOM

THE GOVERNMENT PRINTING OFFICE, WASHINGTON, D. C.

of light galleries runs around the upper part of the boilers, giving access to the valves, which have their stems disposed vertically and upward. Of this gallery there is about 750 ft. The main steam outlet from each boiler connects into a horizontal main by means of a 180 bend of copper pipe, 8 in. inside diameter and 5/16 in. wall, with a single valve in the branch pipe. The main system of steam piping comprises two parallel lines of 12 in. extra heavy wrought iron, one line forming the steam header in the engine room and the other line running along the outside wall of the boiler room, with four cross lines of the same piping as connections between the two parallel lines. This rectangular steam loop has dimensions of about 50 x 103 ft. but as the expansion even in the longer direction of the piping does not exceed ¼ in. no expansion joints have been used. Any boiler can be cut out or in at will, and each of the four cross connections has two valves, so that in case of need the pipe could be cut out at both ends. Along the side walls of the boiler room the steam mains are supported by cast-iron wall brackets, spaced an average distance of 8 ft. The smokestack is built up of steel plate, 150 ft. high and 9 ft. diameter at the top, and is self-supporting. It is mounted on a brick pier with granite coping, 24 ft. square and 19 ft. deep, and at the anchor bolts at the bottom the stack flares out to 17 ft., while it is lined with fire brick for 120 ft. up. Its cap carries a ring of incandescent lamps, which make a conspicuous beacon on special holiday occasions. The boilers are hand-fired with West Virginia bituminous coal, evaporating 10 pounds of water per pound, with steam at 120 pounds pressure, and water delivered to the economizer at 180° F. Coal storage to the extent of about 1,200 tons is provided in the basement of the new building. Feed water for the boilers is taken from two return tanks in the basement below the boiler room, the supply being furnished from the District supply, the condensers of the refrigerating system and from the heating returns. The steam for the feed pumps is taken from an auxiliary set of steam mains. There are eight Worthington feed pumps and eight Worthington circulating pumps, all set on glazed brick piers; the feed in the basement, and the circulating in pairs at the ends of the two rows of boilers, each pair cross connected for interchangeability. The exhaust from the feed and circulating pumps is utilized in two Baragwanath closed feed water heaters overhead in the boiler room. The fittings throughout the system referred to above were made specially of cast steel by the

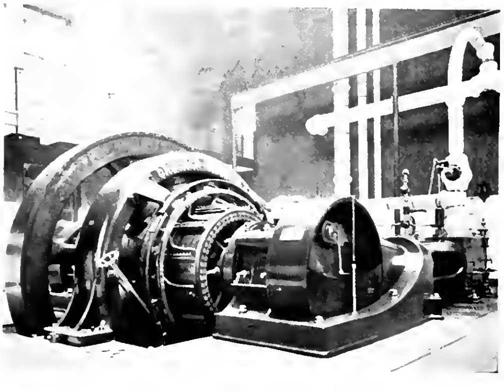

FIG. 10.—ONE OF THE GENERATING UNITS.

Bethlehem Steel Company, and the valves, like the rest of the steam plant, were designed by Mr. Collins.

Other pumps not noted above, but distributed around the power plant or adjacent in the basement, are all driven by electric motor. The vacuum pump for the steam heating system is operated through single-reduction gear by a 15-hp, 120-volt General Electric motor, and the plunger pump for elevating the discharge from the vacuum pump to a tank elevated 10 ft. above it is driven by a double-reduction 3-hp motor of the same make. The pump for supplying water to the spirojector condensers has a double-reduction 20-hp General Electric motor; and the two fire and house pumps, each of 1,000-gallons capacity per minute, with a pressure of 100-130 pounds at the pump, are driven by single-reduction 90-hp General Electric open multipolar motors, shown in one of the engravings. The cooled and filtered drinking water distributed all over the building to some 70 aluminum bronzed iron fountains recessed in the walls is furnished by means of a Knowles triplex pump driven by a 5-hp Crocker-Wheeler motor; and as indicative of the average North American thirst in summer it is interesting to note that the plant cools down daily not less than 4,000 gallons, or not less than a gallon to every parched employee in the Office. The time-honored, hard-worked "growler" of the printing office of one's youth is, indeed, remote and out of date.

THE SWITCHBOARD, ETC.

The main features of the boiler, engine and dynamo equipment having now been considered, it is time to speak of the other not less

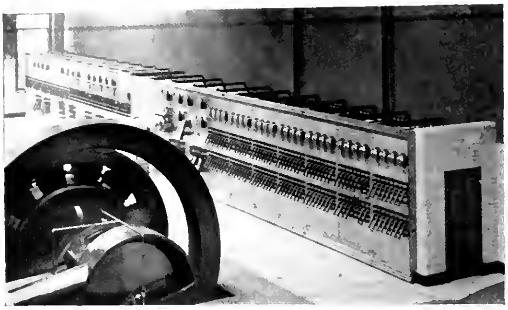

FIG. 11.—VIEW OF SWITCHBOARD FROM GALLERY.

important parts of the plant, such as the switchboard, which itself constitutes a striking element of the ensemble. It will have been gathered from what has been said that the Printing Office is one of the show places of Washington, and the power house is a part which visitors always take in. The handsome skylighted room is very light, not only because of the glass monitor roof, but on account of the interior lining of glazed white brick to a height of 9 ft., with red-faced brick above. The gallery floor and that of the engine room in front of the switchboard and around the side is of marble mosaic in figured panels; while within the brass railing around the generating units the floor is composed of cast-iron plates. The roof trusses and the traveling crane are painted in an agreeably cool shade of green, and the total effect of the room is excellent, the machinery and the switchboard being set off in artistic relief. The crane is an electric one of 25-tons capacity, built by Pawling & Harnischfeger, of Milwaukee, and supported by columns of 6-in. heavy wrought-iron pipe filled with concrete set about 14 ft. apart. The girders are braced to the structural framework of the building and these lateral braces support the steam header in the room.

The switchboard here shown is of a pinkish gray Tennessee marble, 82 ft. long and 9 ft. high, standing about 6 ft. from the wall and accessible from both ends. There are two sets of bus-bars, one for light and one for power, and this subdivision of service is maintained throughout the building, although the generator switches are double-throw, so that any generator can take care of either set. These switches are also double-pole, the equalizer switches being separate. A 5,000-amp. tie-in switch has also been provided of the circuit-breaker type without the automatic tripper, for connecting the two sets of busses together. There is likewise a large single-pole, single-throw switch for connecting together the light and power equalizer busses, in case two generators should be operating one on light and the other on power, with the tie-in switch closed. Each of the feeder switches are double-pole, double-throw, so that they can be independently thrown on either set of bus-bars. The board is virtually in two sections, the latest section for control of supply in the new building having been built by Albert & J. M. Anderson Manufacturing Company, of Boston, and consisting of nine panels, with a length of 34 ft—two generator panels and seven feeder. Here the feeder switches are in two rows. One set of busses extends along the middle of the panels in the rear of the board, with connections to feed both rows of switches, the upper ones when the switches are in the down position and the lower ones when the switches are in the up position. The other group of bus-bars is subdivided into two sets, one for the upper position of the upper row of switches and the other with less copper being installed only as a safety or emergency provision for the lower position of the lower row. All the feeders are protected by I. T. E. circuit-breakers mounted on marble panels at the rear of the board, and the generators also are protected by I. T. E. circuit-breakers behind the board, which can be thrown by means of push buttons on the front of the board. These breakers were supplied by the Cutter Electrical & Manufacturing Company, of Philadelphia, whose contract called for two 5,000-amp., double-pole circuit-breakers, 28 double-pole, breakers of 300 amp., and 28 double-pole, 600-amp. breakers. The Anderson contract on the new board called for the two 5,000-amp., double-throw knife switches; two 5,000-amp., double-pole, single-throw knife switches; one 5,000-amp., single-pole, single-throw and 56 600-amp., double-pole, double-throw knife switches, all of which are of special design, hand-finished, while the clamping nuts, bus connections, etc., have ground contacts.

The new section alone of the board carries about 25,000 pounds of copper exclusive of the measuring instruments, which include two illuminated dial voltmeters 0-150 volt, one illuminated differential voltmeter, two illuminated ammeters 0-6000 amp., one illuminated ammeter, 0-5000 amp.; 20 round pattern ammeters, 0-500 amp., and eight round ammeters 0-750 amp. All these were made by the Weston Electrical Instrument Company, of Waverly, N. J., and are finished in copper and black. The leads of the two large generators are also brought out to two Thomson recording wattmeters furnished by the General Electric Company, each with a capacity of 5,000 amp. at 125 volts. A tell-tale panel of all wattmeters is placed also in the office of Chief Electrician Tapley, who has spacious quarters, with filing cases and other adjuncts, on one of the main floors near by. A daily log is carefully kept of current output, based on 15-minute readings, and checking up each branch of supply. Some idea of the work done can be formed from the fact that the recent daily load in December, when the new building had hardly got into shape, has been from 8,200 to 8,900 kw-hours daily, and that during November the total output was not less than 167,000 kw-hours.

The board itself is bound by handsome heavy copper moulding, with iron framework, and angle-iron braces, cable carriers, etc., all of which was given two coats of the best asphaltum paint. Every detail of the board has been most carefully planned out for safety and perfect finish. No electrolytic copper was allowed, all being pure Lake (Calumet & Hecla) rolled hard-drawn, or soft-drawn, according to the part. Bolts used in making the electrical connections are made from hard-drawn brass rod, with solid heads and all flanged nuts are of pure cast copper. All finish on the front of the board, of switches, brackets and connections, is "drawn file finish"; all surface contacts are made with ground joints, and all edges are champered 3/64 in. Standard requirements in every respect pushed to their limit have been deemed none too good for the board and its accessories, in view of the imperative necessity of maintaining service at all times under all contingencies.

Back of the board extends a rubber-covered walk and a ladder drops down to the engine room basement, where the system of distribution from the board may be said to begin. The conductors as they leave the board and enter the iron conduits against the outside wall of the power house being shown in one of the cuts herewith.

Lighting the Tuileries.

Reports from Paris state that the lighting of the Tuileries Garden is not yet an accomplished fact. There have been differences of opinion between the State, the owners of the property, and the authorities of Paris as to which of the powers should direct the works. The question is now decided in favor of the State, and though the city engineers are actually conducting the operation of laying down the wires, it is under the superintendence and direction of the French Government. A further difference arose over the design to be employed for the lighting standards. The model submitted to the State architect by the municipality was rejected as bearing the arms of the city, and M. Redon has now himself designed and had cast a very artistic candelabra, which will be adopted. The new lamps are of the style known as "Art Nouveau," and are far finer than those proposed by the city. They will bear comparison with the four beautiful standards which now adorn the four corners of the Place de la Concorde, or with those others, different but equally handsome, around the Opéra.

Testing Large Alternators.

By W. E. Burnand

THE tests mainly required on alternators are for efficiency, regulation on unity and lower power factors, and for heating under load. Two methods appear to be available for making these tests; first, by the rather barbarous method of loading up the machine with resistances, choking coils, etc., or, second, by more scientific methods which may be said to have had their commencement with Hopkinson, in which the machine under test and other apparatus connected with it are supplied only with the amount of power lost in the system. Unfortunately, the second method as hitherto practiced seldom gives results strictly comparable with what will occur in actual use with the machine, and so though it may be said to be scientific, if by science is meant measurement, it is hardly so if by this is meant measurement of the thing you want to measure. The first method, however, is so cumbersome and expensive that in the case of really large alternators, it becomes quite

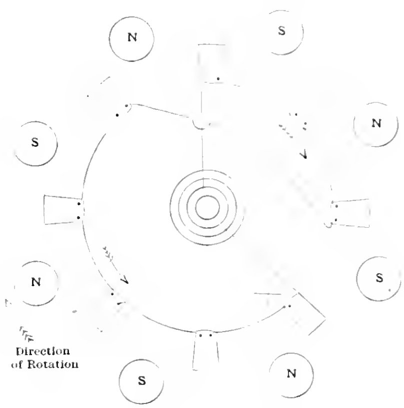

FIG. 1.—DIAGRAM OF COIL CONNECTIONS.

impractical, and the machine either has to go untested or some modification of the second class made, and the results that will occur in use with the machine deduced therefrom.

When two machines of equal capacity are available, they may be coupled together and the Hopkinson test pure and simple carried out, the power factor of the load being varied as desired by manipulation of the field strengths. As a rule, however, two machines are seldom available and recourse must then be had to opposing half (approx.) of the armature to the other half and circulating current through the windings in the manner described by Mordey, Behrend and others. But the methods that I have seen described have always been open to some great objection, such as, when the armature is the rotating part, putting great unbalanced strains on the machine, causing vibration which in some cases endangers the integrity of the machine, and also, in the majority of cases, the armature reaction and consequently the core losses and regulation observed are entirely unlike what will occur in actual use and, therefore, vitiates the results obtained as tests for regulation, efficiency or heating under full-load conditions. It seems to the writer that these objections can be overcome in a simple manner by the following methods:

First, as to the unbalanced strains in the machine, the cause of this will be readily understood by reference to the diagram, Fig. 1. Fig. 1 represents an eight-pole alternator, connected so that three coils oppose the other five. Connected thus, the five coils circulate a current round the armature against the e.m.f. of the three coils, the strength of which can be regulated by the field strength or by means of a rheostat in circuit. Thus half (approx.) of the armature will oppose the rotation of the machine, and the weaker half will help it, the difference in rotative effort plus friction having to be supplied from an external source. The arrows in Fig. 1 show the direction of this effort exerted by the two sides of the armature, from which it will be seen that both tend to force the armature in the same direction. If the armature is stationary, this is not usually of any great consequence; but if the armature is rotating, the effect is just the same as if a heavy weight were located at the point marked *x*, which naturally tends to put severe strains on the framework of the machine. This could be balanced by a weight on the opposite side, whose value could be calculated from the apparent horse-power of the machine, the peripheral speed, diameter and power factor; but a much better way would be to prevent these strains altogether, by dividing the armature circuit into quarters instead of halves, as shown in Fig. 2, coupling *A* and *C* in series, opposed to *B* and *D*. By this means the stresses, which are indicated in the figure by arrows, balance themselves round the circumference of the armature, leaving no unbalanced strains to be transmitted through the shaft to the framework of the machine.

Having got over this difficulty, there still remains that of armature reaction. The difficulty here results almost entirely from the great lag or low power factor of the currents circulating round the armature, when the current is caused to circulate by a higher e.m.f. in one-half of the armature than in the other half. Thus, the current in the coils is nearly at its maximum when they are directly opposite the pole pieces of the machine, whilst with a power factor of unity the current is zero in this position, the conditions being reversed again in the midway position, i. e., the lagging currents are nearly zero here, whilst the power factor current should be at its maximum. It is evident that this must have a great effect on any test for regulation or efficiency. The power factor having comparatively little influence on the poles, whilst with currents lagging nearly 90° the coils on the weaker half have a powerful tendency to help the magnetic field, and on the stronger half a powerful demagnetizing tendency, thus giving rise to induced currents in the magnetic system, and also affecting the core losses of the machine. The mechanical strains also are not those met with in use; there is more tendency to vibration, and less of a straight pull or push backwards on the coils than is the case under load, when the current through the coils is at a maximum at the point midway between the poles; hence, in a position of maximum effect.

The effect this has with a current lagging about 90° is that for

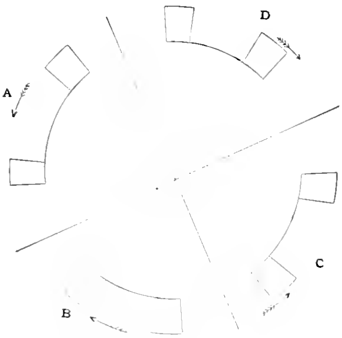

FIG. 2.—DIAGRAM OF ARMATURE CONNECTIONS.

every time a coil passes a pole-piece it is first subjected to a force in a backward direction till it gets opposite the pole and then in a forward direction till in the midway position. Thus there is a severe racking strain backwards and forward at the rate of four times the frequency of the machine, whereas with a current in phase with the e.m.f., the strain is always in one direction, either backward or forward considered with respect to the direction of rotation, according as the current circulates with or against the e.m.f.

The method devised by the writer to overcome these difficulties is to connect up the armature as in Fig. 2, the number of coils in the quarters *A* and *C* being equal to those in the other two quarters, *B* and *D*, so that the e.m.f of two quarters opposes and balances the e.m.f. of the other two quarters, and to circulate an alternating current through the armature from an external source of the same frequency as the machine under test, and whose phase with relation to this machine may be readily adjusted. This external source may consist of a small alternator with the same number of poles as the machine under test, and coupled to the same shaft; or it may be a machine of a different number of poles, driven from the shaft through chain or spur gearing. This machine, of course, may be in circuit with the large one, either direct or through a transformer, and need only be of a size capable of supplying the electrical losses in the large generator and connections. By this arrangement practically all the effects of full load can be simulated, in a manner to get practically reliable results. The auxiliary alternator can be so driven with relation to the machine under test as to circulate a current of leading, lagging or any desired power factor.

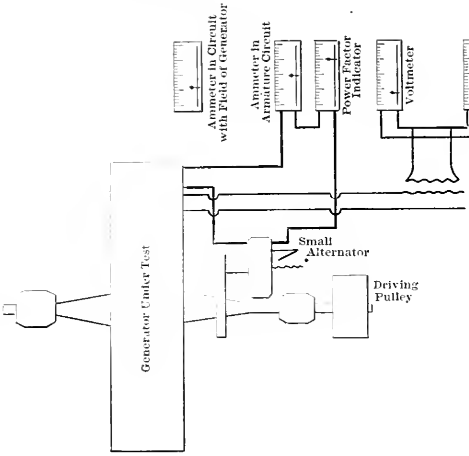

FIG. 3.—DIAGRAM OF TESTING APPARATUS.

The heating can, therefore, be determined for any of these conditions, and the regulation likewise. The efficiency can be determined from the balance of power required to drive the machine at its working speed with full load current circulating through the armature (at any desired power factor), after subtracting the power lost in the outside connections, the auxiliary alternator and the gearing driving it, all of which can be easily determined with an accuracy near enough to give materially correct results for the machine under test.

Fig. 3 shows the manner of testing the regulation of the machine, the voltmeter and power factor indicator being in connection with the half of the machine in which the current flows in the direction of the e.m.f.; the frequency meter being connected any convenient place, say in parallel with the voltmeter.

A reading is first taken with no current passing through the armature; afterwards a reading is taken with full-load current passing, the power factor of which can be regulated by causing the auxiliary alternator to lead, lag or keep in phase with the e.m.f. of the machine under test, the amperes being readily adjusted by a rheostat in the field of the small alternator.

Assuming the speed kept constant, the difference in the two voltmeter readings gives the drop in half the armature. If the machine is designed to work with the armature coils all in series, the regulation is, of course, double this value; if the two halves are to be in parallel the regulation is direct as given by the voltmeter readings. Should it not be possible to get the speed quite the same as when unloaded, the effect of this can be calculated from the difference in frequency—the e.m.f. being proportional to this at constant excitation.

A variation of this method might be to have a voltmeter on each half of the armature, the difference in the readings with full-load current passing giving the regulation; but the first method is probably preferable for a generator, as the armature reactions in the half referred to more nearly approach those of practice than is the case in the other half of the machine in which the current circulates against the e.m.f. as in a motor.

German Telegraphs.

Data to hand show that domestic telegraph business in Germany in 1902 was 43 per cent. above 1892, but it is said that business of Stock Exchange houses fell off 18 per cent. This may be due to the official restrictions on speculation.

Electrical Plant of the Lackawanna Steel Company.

THERE is now in process of completion, with part of the plant already in successful operation, a modern steel plant in which the electric current finds extensive application. The installation will serve to show the great strides being made in the use of electric current as an aid to the metallurgical engineer. Many of the applications are of especial interest to the latter because of the use of electrically-operated machinery where formerly the steam engine was almost exclusively employed. Other applications are of greater interest to the electrical engineer as having necessitated the solution of purely electrical problems. The plant further embodies features which are representative of the highest type of industrial engineering. It is true that all the advantages of an admirable site and ample capital are available. Nevertheless, the design embodies features which will conduce to the lowest operating cost consistent with a wise initial outlay.

The Lackawanna Steel Company was incorporated in 1902, with a capital of $40,000,000, to absorb the Lackawanna Iron & Steel Company and the Lackawanna Coal & Coke Company, the latter owning bituminous coal properties. The former operated a plant at Scranton, Pa., for the manufacture of steel rails, billets and merchant iron, and also several blast furnaces at various points. A site was purchased at Buffalo, N. Y., with a view to the removal of the Scranton plant to that point.

The output of the plant will consist of finished steel made by the Bessemer and open-hearth processes. As the produce of the plant is produced from raw material exclusively, the process will involve all the operations of coking, smelting, Bessemer and open-hearth steel making and the rolling of rails, billets, shapes and plates. The manufacture of the steel will further necessitate the storage and handling of very large quantities of ore, pig iron and coal, and the production, distribution and application of various systems of power and an auxiliary plant for the maintenance of the buildings, equipment and tools.

The tract of land acquired is about 3½ miles in length and nearly one-half mile in average width, on the south shore of Lake Erie, a short distance from Buffalo. The land adjoins the extremity of the United States breakwater, which affords a safe and commodious landing at the south end of the property. Here a ship canal 200 ft. wide, 21 ft. deep and 4,000 ft. long has been excavated parallel to the shore to afford entrance to ore-carrying vessels. On the opposite side of the property a railroad has been built to connect with the trunk and branch roads entering Buffalo.

The governing principle in the design of the plant has been the arrangement of the various buildings and equipment for the several processes in comparatively long and narrow areas parallel to each other and to the ship canal, such that the material in the various stages of manufacture is advanced progressively with the least expenditure of time and labor. To aid in this a system of longitudinal and belt tracks has been installed throughout the entire plant. Adjacent to the shore of the lake and extending to the ship canal is a complete coke plant, consisting of 940 by-product coke ovens with a capacity of 4,000 tons a day. To the south of this is a coal storage plant and yards for coal trains. Coal is received by rail and about 150,000 tons will be stored for emergency use in circular piles commanded by electrically-operated revolving locomotive cranes. Parallel to and approximately 75 ft. from the ship canal is located an ore dock which is about 270 ft. wide and ultimately will have a length of 2,500 ft. This consists virtually of a pocket about 13 ft. deep lined with concrete and supported on piles. The ore dock has a capacity of 750 tons of ore per linear foot, which will be piled on it to the height of about 70 ft. in the middle. The ore is unloaded from vessels and transferred to the former by five ore-unloading machines made by the Wellman-Seaver-Morgan Company, which travel from end to end of the ore dock, and are electrically-driven. Three ore-reloading machines of the same make, also electrically-operated, transfer the ore to steel bins set along the opposite side of the ore dock. Here the various grades of ore from different mines are deposited in separate steel bins.

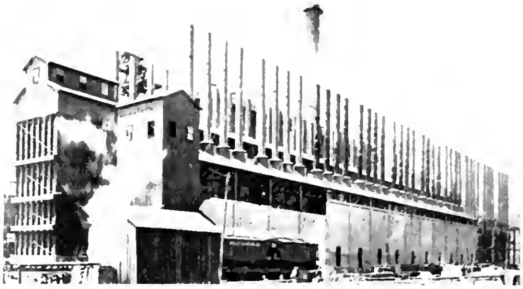

FIG. 2.—GENERAL VIEW OF BOILER HOUSE NO. 2.

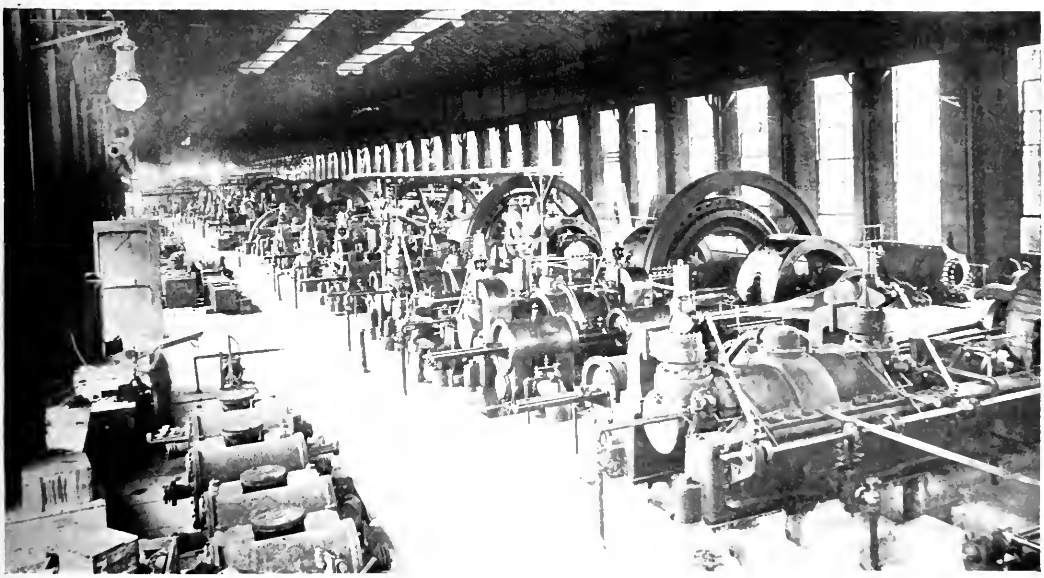

FIG. 1.—VIEW OF POWER HOUSE NO. 1.

After being discharged from these and weighed, the ore with the required amount of coke, limestone, etc., is then hauled by a cable up a steep incline and the contents of the car discharged by an Otis automatic electric machine into the top of the blast furnace. These furnaces extend in a row parallel to the ore dock and storage bins. At present two 300-ton furnaces are in operation, while four others of a capacity of 800 tons are in process of erection. The boiler and engine houses then follow, being arranged in a parallel group about 300 ft. wide and 3,000 ft. long. These separate the steel furnaces and rolling mills from the rest of the plant. Starting east from the lake shore in the various divisions enumerated, the materials are moved transversely in process of manufacture. The Bessemer works are in line with a mill for blooming and finishing heavy rail sections and one for making commercial billets, beyond which are two other rolling mills for light rails and for spliced bars and shapes. The most easterly division will contain the open-hearth furnaces, which are in line with three sets of heavy roughing mills delivering to other mills making finished plates and structural shapes. In these divisions the molten iron is received at the north end, and, passing continuously south without being interrupted or reversed, is carried in a long straight path through all the processes of manufacture. The finished steel is delivered for shipment or temporary storage at the southern extremity of the plant. In the northeast corner, adjacent to the steel furnaces, are located the foundry, machine shop and various auxiliary shops and buildings for the construction and maintenance of the plant.

The general scheme of power supply for such a large steel plant is one requiring a comprehensive treatment of the problems involved, which are not only of an engineering, but economical nature as well. As in the layout of the buildings and of the equipment, such methods and apparatus are adopted as will result in the lowest operating expense consistent with the least investment. The predominating principle, however, considered in the operation of the plant is that of certainty of operation, and the design consequently is affected to that extent. Economy is of minor importance, although receiving

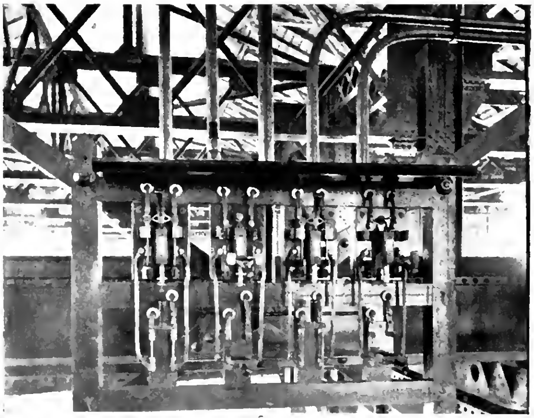

Fig. 3.—Switchboard for Transfer Table, Bessemer House.

attention wherever possible. As a consequence, the utilization of by-products has affected the problem materially.

The installation is of unusual interest, as affording a means for the study of the various motive powers as applied in a steel plant which is being erected under the most favorable conditions at the present time. The steam engine will be used exclusively for the roughing and blooming mills, as rolling mill service has been held to be too severe for the electric motor. The gas engine, not being readily reversible, is not available for this class of work. The steam engines will be run condensing, a practice not heretofore adopted in this country, although triple-expansion condensing engines are in use in such service in Europe. Gas engines of 1,000 and 2,000 hp, utilizing blast furnace gas, are employed to drive the blower engines of the blast furnaces. Although engines of the same type, but smaller capacity, have been employed in similar service in Germany, this is the first instance of their use in this country. What would otherwise be a waste product is thus utilized to advantage and at a greater economy in the gas engine than if used in the boiler plant, and its energy finally made use of in the form of electric current for driving blower engines. The investment required for any given capacity is without doubt also materially reduced.

It will thus be seen that the steam and the gas engine are employed at all points which are vital to the carrying out of the various processes for the production of the finished steel. Furthermore, it will be found that the aggregate horse-power of these greatly exceeds that of the hydraulic, pneumatic and electric machinery employed. The electric drive, however, will be extensively employed for live operations, and more especially in that part not directly concerned in the production of the finished product, as in the coke and ore-handling and the auxiliary plant. The electric installation, furthermore, is of especial interest, as both direct and alternating current are used, the former for crane and variable-speed motors and the latter for constant-speed work. Hydraulic and pneumatic machinery is installed

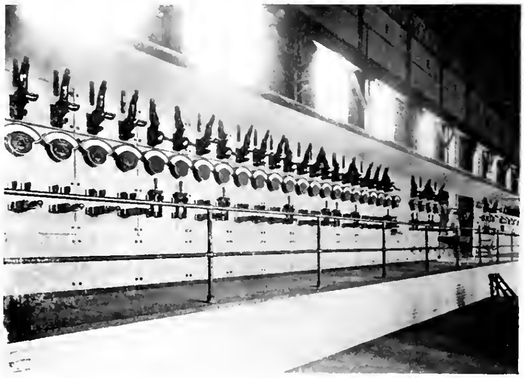

Fig. 4.—Switchboard in Power House No. 1.

under such conditions as are most favorable for its use or where absolutely necessary, as for instance, in the use of compressed air for the starting up of the gas engines.

As a consequence, one large central power house has not been erected. Each pair of blast furnaces is served by its own power plant operating the blower engines. Boiler houses are being erected at such points as will most economically supply steam to the steam engines located in the various mills. The main power house, which contains the electrical plant, as well as a pumping station which supplies the entire plant with water, receives steam from one boiler house which is located a short distance from both. Part of the boilers in the various boiler houses are fired with blast furnace gas. To insure against interruption of service and possible break-downs, the various boiler houses are interconnected by an equalizing steam main. This will also serve to take care of any sudden excessive demand at any point in the plant. This same principle is also pursued in regard to the supply of gas for the gas engines located in the various power houses. The plant when completed will also contain a producer gas plant from which the gas will be piped to the various gas engines for use in cases of emergency. As already stated, certainty of operation has been considered paramount in the design and operation of the plant.

Boiler house No. 2, which is the larger one of those at present constructed or contemplated, presents several interesting features. Although this contains Cahall vertical water tube boilers of a total capacity of 20,000 hp, a 250-hp size has been adopted, each boiler having its own independent stack, as will be seen in Fig. 2. Another feature which is of interest in the comparatively small coal storage capacity which has been provided, as coal is readily obtainable from the coal storage yards located near the coke plant. The capacity of the bins is merely such as to tide over any irregularities in unloading. Special precautions have been taken to prevent a shut-down. The main steam heater consists of a ring main with branches for power house No. 2 and the pumping station taken off at two points. Valves have been installed at various points such that one-quarter of the total number of boilers can be cut out at any time without in any way interrupting the service.

The boiler house is of the steel skeleton brick curtain wall type of construction. It is 68½ x 460 ft. in size, and contains 80 Cahall vertical water tube boilers arranged in two rows facing each other in batteries of four each; 48 of these are equipped with Roney stokers, whereas 32 will be gas fired. As the surplus blast furnace gas will be utilized in this plant, the boilers are equipped with grates for hand firing. This will be resorted to whenever the supply or the quality of the gas is deficient. It is also necessary for starting up a boiler. The blast furnace gas is not purified, although pockets are provided in the supply pipes at the boilers for the deposit of any dust contained in the same. It may be mentioned here that this will be the only plant requiring coal as a fuel, as the others will be gas fired exclusively.

As the steam header is more than 500 ft. in length, it has been anchored at the center of each side of the boiler house. A double bend is provided in each line, connecting a battery with the main header to take care of expansion. A very long elbow is provided at each boiler, which, by closing two valves located between the header and the former, can be entirely removed to permit the removal of tubes. A monitor in two halves of a larger diameter than the boiler is bolted to the roof over each. This can be entirely removed for repairs of whatever nature, and also serves as a ventilator. All steam valves 12 in. long or larger are by-passed. Drips under operating conditions are exposed, and 8-in. cast-iron pipe is used for blow-offs in the ground leading to the sewers. Compressed air is used for blowing out and feed water for washing out boilers. The stacks are 28 in. in diameter and 75 ft. in height above the grates. A boiler pressure of 125 pounds is carried, but this is reduced to 80 for some of the old machinery.

The coal storage plant consists of a tower to the south of the boiler house. This contains two bins, one of the 200-tons capacity called the service bin, and a reserve bin of 300-tons capacity. The coal in the latter is available for use in the boiler house only on being discharged and re-elevated to the service bin. The coal is discharged from railroad cars and delivered by a scraper conveyor from the hopper underneath the track to the flight conveyor, which in turn elevates the coal to either bin. A traveling coal pocket equipped with two 7-ton coal bins, receives its coal from the service bin and conveys it to any required point. This is in the nature of a [illegible] crane, and its character can be readily understood from Fig. [illegible]. The ashes are discharged in the basement into a pocket of a capacity of 28 cu. ft., which travels on an overhead trolley. From this the ashes are dumped into a skip, which elevates them to the ash bin, from which they are automatically discharged into cars as desired. All of the machinery is operated by direct-current motors. The coal handling and ash-conveying systems were designed by Heyl and Patterson, of Pittsburg.

Boiler house No. 1 in its general features is similar to the one already described. This contains 16 Cahall boilers, which are provided with grates and gas fired. Coal is used whenever the blast furnace gas is of an inferior quality. Boiler house No. 3, which is south of the pumping station, is 65 x 184 ft. in size. This will contain 32 Cahall boilers gas fired, and will furnish steam to several engines in the Bessemer rail mill.

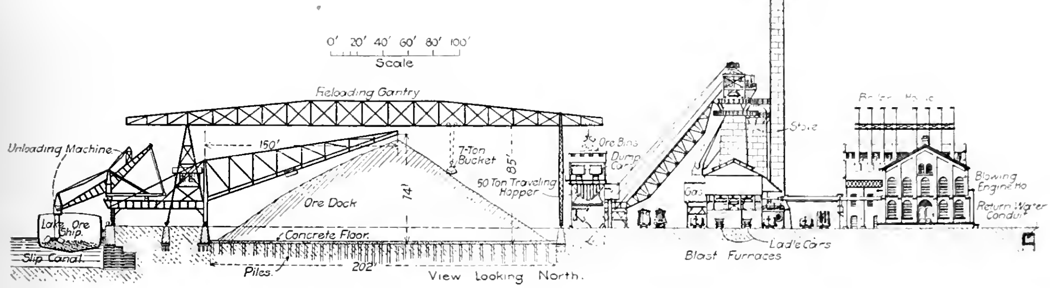

FIG. 5.—SECTION THROUGH ORE DOCK AND BLAST FURNACES.

As already stated, each pair of blast furnaces will have its own power house, containing an equipment of gas engines for driving blower engines. By utilizing the blast furnace gas in gas engines a saving is obtained as compared with burning gas under boilers, which has hitherto been done exclusively. Only one-third to one-fourth the gas is required by this method as compared with the other, and a further saving is made possible by the omission of the boiler equipment with its attendant cost of operation. The gas engines are of the Korting type, and made by the De La Vergne Refrigerating Machine Company. The engines are operated in pairs, each one being one-half the capacity of the unit and are of the double-acting, two-cylinder type. They differ to a great extent from the gas engines made in this country. The gas used in the engines is taken from the top of each blast furnace through three Downcammer flues leading to a dust collector. After being purified in centrifugal washers operated by induction motors, and its temperature reduced to about 80° F., the gas is delivered to the mains at a pressure of about five ounces. Each engine is equipped with an electric speed governor. A Monarch engine speed limit switch is belted to the engine shaft. This switch, when the engine exceeds a given speed, closes a battery circuit in which a solenoid is connected. This sole-

FIG. 6.—ELECTRIC ORE UNLOADER IN OPERATION.

noid operates a multi-point switch, which short-circuits magneto igniters of the engine, and consequently there are no more explosions in the engine cylinder until the speed falls to normal.

Blowing engine houses Nos. 2 and 3 will contain eight 200-hp engines each. As each pair of blast furnaces is operated as one unit, and as the utilization of the excess at any other point would involve an expensive pumping plant, besides introducing complications, it is self-evident that such a course is the most economical one to pursue. The blowers in blowing engine house No. 1 are operated by steam engines which were in use at the Scranton plant. Boiler house No. 1, which supplies the steam for these engines, has already been described. The use of the steam engine was resorted to in this instance because new machinery of the required type could not be obtained in time. The gas engine plant will probably displace the present one at some time in the future.

A pumping station which supplies water for the entire works has been built south of boiler house No. 2, from which it obtains its supply of steam. This contains at present two 50,000,000-gallon Wilson-Schneider direct-current, triple-expansion pumps. The pumping plant has its own Weiss counter-current condensing plant, built by the Southwark Foundry & Machine Company. The circulating and air pumps are operated by Porter-Allen engines. A 100,000-gallon water tank has been installed, from which 14 16-in. lines radiate. The water is obtained through a concrete tunnel from the lake.

Power house No. 2, the first to be built, was used during the early construction period, and is held in reserve at the present time. Power house No. 1 is the most centrally-located and the most important. It contains the electrical plant, the air compressors, the hydraulic pumps and several blowing engines for the Bessemer plant; in fact, all of the power plant which it has not been considered advisable to install in separate power houses. It contains all machinery for the generation of power which is to be distributed in small units over the entire area of the works. The power house is 77 x 725 ft. in size, and of the same type as employed for all buildings, namely, steel skeleton with brick curtain wall construction. A 25-ton electric traveling crane built by the American Engineering Company commands the entire floor space. It is heated by the Buffalo Forge Company's hot blast system.

Compressed air for the various pneumatic tools used throughout

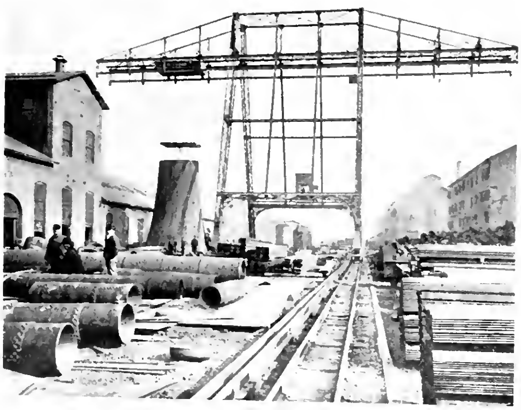

FIG. 7.—LARGE ELECTRIC GANTRY CRANE.

the works for operating the bells of the blast furnaces, for starting the gas engines and for many minor purposes, is supplied by four 14 x 16-in. Ingersoll-Sergeant cross-compound air compressors, each rated at 950 cu. ft. of free air per minute at 100 pounds pressure. Pneumatic machinery for tilting converters, manipulators, etc., is operated by water at a pressure of 450 pounds, three accumulators being installed in the building. There are two Snow and two Knowles 20 x 9 x 36-in. duplex pumps and seven 29 x 9½ x 36-in. Worthington pumps. The boiler feed pumps for power house No. 2 are also installed in the building. There are one Blake and three Knowles 30 x 16 x 24-in. pumps. The blowing engines housed in the power house supply air to the converters in the Bessemer steel department. There are four of these, two of these having engines 52 x 60 x 60 in., and two 50 x 54 x 60 in., made by the Allis-Chalmers Company. The engines are condensing. A 9,000-hp Weiss counter-current condenser has been installed. The exit pipe located in the basement is a built-up riveted wrought-iron pipe, which increases in size from 24 to 66 in. The circulating and air pumps are operated by Porter-Allen engines. The condensing water is supplied by the pumping station.

The electrical equipment of the power house presents several interesting features. The size of the generators has been limited to 500 kw, as gas engines of a larger size than 1,000 hp were not considered practicable at the time the plant was designed, although as already noted, engines of 2,000-hp capacity are being installed at present in the blowing engine houses for the blast furnaces. Another

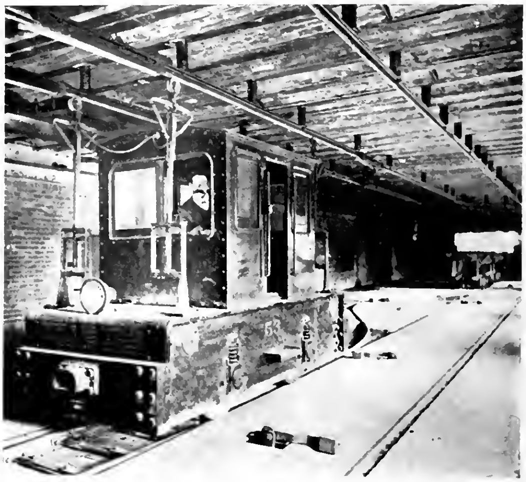

FIG. 8.—ELECTRIC LOCOMOTIVE, BESSEMER HOUSE.

feature is the use of both direct and alternating current in the plant. This course is more than justified when it is considered that large units were impracticable, and further that there are five direct and five alternating-current units of 500 kw each. Nine of these are driven by gas engines, whereas the other, a direct-current generator, is driven by a 36 x 48-in. Porter-Allen condensing engine. This unit is held in reserve for use in case the supply of gas is deficient or should fail entirely. The alternators are three-phase, 23-cycle, 440-volt machines of General Electric make, whereas the direct-current generators are 250-volt Sprague machines.

As gas engines are employed to operate the alternators, a somewhat unusual condition, these are guaranteed to operate successfully in parallel on condition that the maximum variation in speed of the revolving fields shall not exceed .2 of an angular degree on either side, of uniform speed, and to operate without cross currents should a means be adopted for mechanically coupling together when in place. There will be some thousand motors eventually, of a rated capacity of about 32,000 hp. The gas engines driving the generators are similar to the 2,000-hp units already described. These engines have cylinders 23¾ in. in diameter with a stroke of 43¼ in., being operated at 100 r.p.m. The generators are mounted on a crank shaft between the two engines. The cooling water for the cylinders is circulated by centrifugal pumps made by the Lawrence Machine Company, driven by Westinghouse induction motors. The engines are started with compressed air from the compressed air lines. There are three exciter sets, each consisting of a General Electric 125-volt, 37½-kw generator, direct-connected to a 10 x 10-in. Harrisburg Foundry & Machine Company's engine. There are also three 115-light, 6.6-amp. Brush series direct-current arc light machines, direct-connected to 1,000-hp General Electric induction motors.

The switchboard (Fig. 4) is simple in its design and substantial in its construction. It is built on a slightly raised platform, commanding a view of the electrical machinery. There are three sections, separated from each other, there being an alternating and direct current and a series arc board. The direct-current switchboard consists of five generators, one load and 14 feeder panels, the latter containing two circuits each. Each circuit is equipped with one double-pole, double-throw switch, a 2,000-amp. ammeter and a circuit-breaker in one leg of the circuit only. The bus-bar copper has been figured on a basis of 800 amp. to the square inch at normal load. Although all circuits are protected by circuit-breakers, this is done nevertheless in such a manner that certainty of operation is assured, and at times a piece of apparatus may be sacrificed in maintaining an uninterrupted service. The alternating-current board contains five generators, one exciter, one load and 20 feeder panels, each of the latter containing two circuits. These are provided with instruments and switches, as in case of the direct-current circuits. Each circuit will eventually be equipped with an integrating meter. The alternating and direct-current switchboards were built by the Westinghouse Electric & Manufacturing Company, in accordance with the company's designs and specifications.

All feeders and mains are run in conduits, lead-covered paper-insulated cables being used. The conduit is built of tile in the usual manner, but on account of the mucky soil, special expedients have been adopted to maintain alignment. At intervals of 30 to 35 ft. a couple of piles are driven on 4-ft. centers, which are capped, and serve to support concrete steel cantilever arches, which in turn carry the current. In building the underground system, the ground is removed to the contour required, thus saving the expense of forms for the concrete arches. In the design of the distributing

FIG. 9.—PIG IRON MAGNET.

system the limiting condition was not the drop in potential, but rather a five-watts loss per duct-foot in the underground system. All cables for direct-current circuits are 1,000,000 circ. mils single-conductor cables, made by the National Conduit & Cable Company. Those for alternating current are three-conductor No. 0000 cables of Standard Underground Cable Company's make.

The yards are lighted by series direct-current arc lamps, for which ornamental cast-iron posts have been erected at various points. The buildings and shops are lighted by constant-potential arc lamps and incandescent lamps. The former are placed two in series on a 220-volt, direct-current circuit. Current from the 440-volt alternating-current circuit is stepped down by means of transformers for incandescent lighting. As 25-cycle currents are employed, three lamps connected between the different phases are installed near each other, thereby obviating any disagreeable physiological effects.

The electric motor, as already stated, was considered not able to meet the severe and fluctuating demands of rolling mill service. The steam engines used for this purpose are of the reversing twin-cylinder type, geared about 1 to 2. To provide an elastic medium between the engine and the load, recourse has been had to a fly-wheel whose rim is driven by means of heavy springs from a spider keyed to the driving shaft of the mill engine, the spider and the inner shaft of the fly-wheel having a number of corresponding toothed projections. Then engines are operated by [illegible] entirely, although equipped with link motion. The ma[illegible] times will reach 6,000 to 8,000 hp, and because of the num[illegible] passes the load will fluctuate from nothing to a maximum [illegible] 30 to 40 times in one minute. A continuous-indicator diagram may be likened to an alternating-current diagram, the amplitude being largest at the beginning and then increasing as the number of passages increases, this cycle of operations being repeated several times in a minute. The engines in this case will be condensing, a course not hitherto pursued in this country, although triple-expansion condensing engines are in use in such service in Europe. Each rail mill will be equipped with its independent Weiss counter-current condensing plant.

The use of hydraulic and pneumatic machinery throughout the works is practically limited to such conditions as are most favorable to use of either as against electrical machinery, although the division line is not always clearly drawn, depending to a great extent upon the variability, accessibility, etc., of either. Compressed air is used for various pneumatic tools in the shops, for operating the bells of the blast furnaces, for starting the gas engines, and similar purposes. Hydraulic machinery is used for tilting converters, furnaces and mixers, for operating car pushers, hoists and transfers in the rolling mills, and in such places where a large amount of power is to be exerted with certainty within the range of a piston stroke. Although the use of the hydraulic motor is confined to the operation of cranes, hoists, shop tools and auxiliary machinery in the various processes, it nevertheless occupies no insignificant position in the operation of the works. As already stated, the application of the electric motor in many instances is of unusual interest to the metallurgical engineer, although not in itself having necessitated the solution of any new electrical problem. In many other instances electrical methods have been introduced in the various processes. In other cases original electrical problems of unusual interest to the electrical engineer have been solved. The alternating-current motor is used only for continuous service, where ordinarily a shunt-wound, direct-current motor would have been installed. The use of the alternating-current motor in such cases possesses inherent advantages, as the absence of a commutator, its dust-proof character, etc., are too well known to require extended comment. The direct-current motor of the series, compound and shunt-wound type is used for all cranes and intermittent service necessitating frequent reversals.

The application of the electric motor to the driving of roller tables in the various mills has also required the solution of a difficult problem, which has been done in a most satisfactory and simple manner. The conditions in this case are similar to those met with in the operation of the engines driving the various mills, which has been described.

Another problem, which was successfully solved by Mr. E. D. Edmonston, the electrical superintendent, was the design of an electromagnet, which would successfully handle pig iron as thrown promiscuously in piles. Such conditions, of course, are not conducive to the handling of material on as economical a basis as in the case of plates and similar material. The electromagnet shown in Fig. 9 weighs $3\frac{1}{2}$ tons and has a lifting power of $1\frac{1}{2}$ tons. The features of the design are the use of adjustable poles which allow the picking up of the iron in any position. These are bi-polar and separated some distance, so that the flux will penetrate the pole to a great depth. To separate the poles such a distance in an electromagnet of such a size requires very large and deep windings, for which it is necessary to provide special facilities for ventilating, which is accomplished by inserting fibre rods. Being used under all sorts of conditions, the magnet has been designed in such a manner as to be protected in all kinds of weather, and to permit of ready repair. It furthermore combines mechanical strength with excellent electrical features, to withstand the rough handling to which it necessarily will be subjected.

The installation of electric traveling gantry cranes in the yards required the placing of the conductor at such a point as not to interfere with the conveying of material in any position to any point in the yard. On account of railroad tracks which cross those of the gantries, a continuous conductor, furthermore, was not feasible, as an exposed third rail could not be adopted, on account of the danger of shocks to the workmen and the possibility of a ground or short-circuit through the throwing of material across the tracks. The system finally adopted comprises a bare (Fig. 8) trolley wire stretched between strain insulators placed in a trough formed by two hardwood pieces insulated from the ground. All crossings are bridged by a cable carried in a conduit. In this way it is not possible to make a ground, the trolley wire being placed below the level of the top of the wooden strips, and surface leakage is entirely prevented. The cost of construction is small, and repairs can be readily made. As the two collectors placed on the gantries bridge any opening, excessive sparking is prevented by the collector leaving one section.

Certainty of operation being the most important consideration, and the service required being of the most severe character, special precautions have been taken to prevent interruption of the latter. This is well shown in the case of a system of electric locomotives for haulage which has been installed in the Bessemer plant. There are three Baldwin-Westinghouse locomotives, each equipped with two 35-hp motors, railway rating. The controllers, four in number, are of a very flexible nature, permitting of their movement both in a horizontal and in a vertical plane to allow of the locomotives taking curves readily, as very sharp corners are made. A very substantial trolley construction has been adopted. This consists of a 2½ x 2¾ x ⅜-in. T-iron, insulated from the ceiling I-beams by vulcanized asbestos plates and washers. The trolley wire proper consists of a sheet of copper 18 x 2⅛ in., riveted to the iron. The solid construction adopted throughout is further illustrated at the switchboard, Fig. 3, one of several installed in the Bessemer house,

FIG. 10.—COAL-DISTRIBUTING CRANE, BOILER HOUSE NO. 2.

and which controls several transfer tables operated by series direct-current motors. All wiring is run in Sprague conduit, for which special fittings are employed.

Several interesting applications of electrical methods are in use about the plant. One of these is a mixer valve regulator for controlling the temperature of the hot blast on the blast furnaces. This apparatus consists of a regulating pyrometer with an extended pencil room, on which a fibre cup filled with mercury is fastened, a relay, a magnet and a globe air valve. As the pencil room of the pyrometer moves up and down it makes and breaks a battery circuit at the mercury cup. In this battery circuit is connected the relay which opens and closes a power circuit in which a large magnet is connected. This magnet controls a compressed air valve, and this compressed air valve in turn controls a large mixer valve.

Another application is that of an electric burner for blast furnaces. In the case of "freezing" of tuyeres, cinder notch or iron notch, the obstruction is removed by means of an electric burner. Formerly an oil burner or kerosene blow pipe was used for this purpose. The electric burner equipment consists merely of a brass clamp holding a 2-in. x 72-in. round carbon. A long wooden handle is fitted into this clamp, in order to apply the burner when in operation. A cable is tapped into this clamp, carried through a water rheostat and connected to one side of the direct-current power circuit. The other side of the circuit is grounded to the iron framework of the furnaces when it is necessary to use the burner. A current of from 500 to 1,000 amp. at about 80 volts at the arc is required to remove the obstacles.

The ore-unloading machines already mentioned and shown in Fig. — are electrically operated. In these the walking beam truck, walking beam and movements of a ten-ton bucket are controlled from the inside of the leg of the walking beam by means of small operating controllers connected with Electric Controller & Supply Company's magnetic switch controllers, which are placed adjacent to the motors for this work. It is thus possible to control the movements of the unloader without carrying the heavy power cables down into the leg of the walking beam, where the operator is stationed, and it is thus necessary to run only small flexible wires between the magnetic switch controllers and the smaller operating controllers.

It is impossible in an article of this scope to describe fully the various applications to which the erection of such a modern steel plant gives birth. This is further rendered impossible by the fact that a large part of the plant is still in course of construction, and increased confidence and the experience gained at present may lead to the further use of the electric motor and electrical appliances.

Mr. Henry Wehrum is general manager in charge of the Buffalo plant, and of the other properties of the Lackawanna Steel Company. Mr. F. du P. Thompson is the chief engineer of the company, who, believing that organization is essential to success, has gathered about him a most efficient corps of engineers. It has thus been possible to successfully carry into execution even to the minutest detail the general policies which have been outlined in regard to the construction and the operation of the extensive works. The mechanical engineering department is divided into four divisions—the engineering, the construction, the repairing and construction of shops, and the power and operating division, which is in charge of a mechanical and an electrical superintendent of power. The engineering division, under Mr. A. G. Hamilton, the assistant engineer, designs all of the various plants, buildings and equipment required. Under the former are nine division engineers, each one of whom has his own force of draughtsmen and inspectors, who inspect all work under construction designed by their respective departments.

Commercial Long Distance Telephony.

In discussing the commercial aspects of long-distance telephony, the *Wall Street Journal* remarks: "The consolidation of the 4,000 independent telephone companies in the Middle West, and a connecting up of the toll line system, will be the first real competition that the Bell Company has had in the long-distance service, although the independents have done a large short service business within their respective territories. The weakness of the various independent systems has been in the fact that they had no connection with the hub of the West, Chicago. This established, their position will be greatly strengthened. An authority on telephony says that the profit on long-distance service, excluding that between New York and Boston, is meagre for a distance in excess of 150 miles, and that on account of the extraordinary quality of construction and high standard of maintenance necessary, and regardless of rate the New York-Chicago lines cannot handle a sufficient amount of telephone business to make any profit. It must be remembered that it takes the exclusive use of two heavy copper wires to talk from New York to Chicago, and while a five-minute conversation is going on (to say nothing of loss of time in getting the subscribers together) the telegraph companies with their "quads" and a much lighter wire can transmit in five minutes 40 telegrams, at 50 cents, amounting to $20, as against $9 for a telephone call. Then the cost of maintaining of the lighter telegraph service along side of the railroads is from 25 per cent. to 50 per cent. less than the long-distance wires over the highways.

"Another important fact is that telegraph wires are not transposed, as are telephone wires about every 15 poles. This transposition is very expensive and increases cost of maintenance, as splices and tying to insulation is more frequent. The transpositions in a line of 30 or more wires is enormous, for the position of the wires upon the insulators the entire distance from New York to Chicago is changed about every 15 poles, and if another circuit is added, more transpositions are necessary. Successful service upon highway lines necessitates constant patrol at large expense."

Protection of Electrical Apparatus From Lightning and Other Destructive High Potentials.

By HOWARD R. SARGENT.

ELECTRICAL apparatus installed on lighting, railway, power and high-potential transmission circuits is subjected to abnormally high potential strains through various causes, such as lightning, switching, cables, governor troubles, differences in elevation between different portions of the circuits, etc.

Lightning is, in all probability, the worst of these conditions to be taken care of, and up to the present time we have not heard of any form of arrester which will entirely take care of a direct stroke. When a lightning discharge strikes any part of a circuit, the portion struck is generally damaged to a considerable extent at the point where the stroke takes place, and in a great many cases, if the stroke is near the station, the insulation of the apparatus in the station suffers in addition to the local trouble. We have seen numerous cases where, with the best possible protection, poles have been splintered, lines broken and short-circuits started, which have done considerable damage to all kinds of apparatus.

It is possible to take care of high potentials which are induced on lines through discharges from cloud to cloud, discharges from clouds to earth in the vicinity of the lines, or high potentials which have been merely induced by the presence of thunder storms. It has been observed that these induced charges in circuits may produce high potentials not only between lines and the ground, but between line and line in the same circuit, and it is, therefore, advisable to make arrangements to equalize these high potentials not only from line to ground, but from phase to phase.

Some districts are much more open to atmospheric disturbances than others, and it is often necessary to take greater precautions in some localities than in others, due to this reason. In the Southern States about 70 thunder storm days per year are experienced, while throughout the entire country there is an average of approximately 30 such days per year. Some of the installations in the mountainous States in the West have suffered to a considerable extent through the numerous atmospheric disturbances which occur in that district.

On high-potential circuits of considerable capacity, an arc produced by switching, circuit-breakers, fuses or short-circuits, causes an electrical oscillation of extremely high value. Voltages of more than double normal potential are often produced when connecting a circuit of considerable capacity to the generating system at no load. These high potentials subject the apparatus momentarily to enormous strains, and it is well to have some low break-down path in which the dynamic arc will be immediately ruptured, so that these high potentials will equalize themselves from line to line without damage to the apparatus.

In laying out circuits, it is frequently necessary and desirable to dip underground when passing through cities, or under rivers, etc., and in these cases some form of metal-covered cable is generally used. It has been noticed from numerous installations that high potentials invariably occur where these underground cables are used, due to resonance effects and these high potentials are often of sufficient value to break down the cables themselves, or the insulation of apparatus installed on the lines. The strains very often produce pinhole punctures in the insulation of underground cables and thus relieve themselves temporarily; they may, therefore, remain unnoticed for a number of months until the insulation becomes very much impaired, ultimately resulting in a complete break-down.

Whenever lines contain both inductance and capacity in noticeable quantities, high voltages which endanger the insulation of the whole system, and which it is impossible to detect on ordinary switchboard instruments, may exist. We, therefore, frequently find such abnormal voltages in circuits containing a combination of underground and overhead circuits, and in long-distance transmission lines.

A great many cases have been noted where engines and water wheels have raced, caused by the governors becoming inoperative and high potentials have resulted, which have caused serious breakdowns in insulation. This has generally occurred when a considerable load has been switched off from a circuit.

Particular mention was made at the recent general meeting of the A. I. E. E. at Niagara Falls of the abnormal high-potential strains which have been noted on long transmission lines running through mountainous country where considerable differences of elevation occur between different portions of the circuits. These differences in potentials, are, without a doubt, due to difference in magnitude of the atmospheric electrical potential at different altitudes, and in some cases the condenser effects of the line produce potentials considerably in excess of the line voltages.

In laying out protection against the troubles enumerated above, it is necessary to provide discharge paths from phase to phase and discharge paths from lines to ground with suitable ground connections, except when the circuits are entirely underground, when the ground connections may be omitted. In view of the fact that it is necessary to take care of considerable quantities of current from line to earth when lightning discharges take place, it is advisable to have an arrester of as large current-carrying capacity as possible, and with this in view it is often advisable to install a number of arresters in multiple where the conditions are particularly severe. With regard to potentials between phases, which are more of a static nature, these can generally be equalized with small flow of current.

In discharging a line to ground, the simplest form of discharger would be one single gap, or a series of small gaps with a break-down point just above the voltage of the circuit. Although it has been found that a single gap will discharge a line effectively, the single gap, of course, will not rupture the dynamic arc when it is once started by a high-potential discharge.

With a number of short gaps, it has been found that if a sufficient quantity is used, under certain conditions, the dynamic current is ruptured by chilling the arc down between the numerous cylinders; also due to the fact that in some of the gaps the value of the alternating wave is zero, and, therefore, after a high-potential discharge has passed, the dynamic arc does not start again. This arrangement of a large number of small gaps in series is, however, out of the question as far as practical use is concerned, as enormously high break-down voltage is necessary to overcome the gaps, resulting in injurious strains on the insulation of the apparatus. Under certain conditions of inductance, capacity, etc., a discharger of this construction will not interrupt the dynamic arc.

With a fixed length of spark-gap, a certain number of gaps are necessary before break-down will occur at a predetermined point above the voltage of the line, and this number of gaps has the power of interrupting a dynamic arc formed by a limited current value at the line potential. With this in view, it is necessary to place a determinate resistance in series with the gaps, in order to limit the current to this point. An arrester constructed in this way with non-inductive resistance is the simplest arrangement which can be made, and affords the best protection which, up to the present time, it has been possible to devise.

High potentials between lines or phases occur much more frequently than in the case with lightning, and it is advisable to increase the non-inductive resistance in series with the gaps to considerable extent, as this renders less liable the possibility of short-circuits, and as stated above, these high potentials between phases can be equalized through high resistances as well as through low resistances. A further reason for placing a considerable amount of resistance in series with the gaps when placed between lines is that in case of discharge from phase to phase, if the resistances are low, the circuit-breakers or other automatic devices on the line open, causing temporary shut-down, and this, of course, is inadvisable as well as annoying.

It is advisable to have all of the spark-gaps, resistances and operating parts of high-potential alternating-current arresters entirely in view of the operator, as this enables him to make immediately any changes or repairs which may become necessary during operating hours, and with this in view, it is always advisable to install switches in the lightning arrester circuits so that the lightning arresters may be isolated in case immediate repairs become necessary.

Although considerable doubt has existed as to the advisability of installing reactive coils in connection with lightning dischargers, it is believed by many prominent engineers that reactive coils are of considerable value in connection with the proper protection of apparatus. Without a doubt, the frequency of lightning disturbances varies greatly in different cases, although, as a whole, it is probably high. Inasmuch as the action of the reactive coils is not dependent on the voltage or frequency of the line, it is inadvisable to design a large number of coils having different reactances, and it is evident that a coil can be designed with ample current-carrying capacity, which may be used on a number of voltages, provided it has sufficient insulation for the highest voltage determined upon. In this connection air insulation is preferable between turns and layers, as other forms, due to minute discharges, gradually deteriorate and change, becoming partial conductors.

Protective wires have been used in a great many cases by different transmission companies with varying success, although the experience gained, as a whole, has been in favor of this form of protection. A great many of the troubles encountered through the use of this wire have been due to the selection of improper materials in making the installation. Barbed wire has been used in a great many cases, but the commercial barbed wire purchased on the open market is of very poor quality and has a tendency to hold water in the joints and interstices.

In Kalamazoo, Mich., different forms of protective wire have been used, placed in various relative positions with regard to the circuit wires, and it has been found that plain iron wire installed directly below the transmission wires furnishes practically as good protection as barbed wire installed over the transmission.

As a matter of fact, there are few reasons why this should not be the case, provided the iron wire is properly grounded at every third or fourth pole, as the disturbances which this form of protection is supposed to take care of are generally at considerable distance from the transmission wires. While this form of protection may help out in the case of a direct stroke of lightning, it is not to be presumed that it will prove entirely efficient under this condition of affairs.

While the experience of the above-mentioned company has been that a wire placed below the transmission is as satisfactory as if placed in any other position, it is as well to string it above the transmission lines at an angle of approximately 45° to the outside transmission wires, as without a doubt, this locality will aid in taking care of direct strokes of lightning.

With the improved lightning protective devices on the market, the grounded protective wire need only be resorted to where the most severe conditions exist, and then it should be put up in the most thorough manner with regard to the size and quality of the material used and with regard to grounds.

For direct-current work the general principles of construction mentioned above hold good, but in view of the fact that it is much more difficult to rupture a direct-current arc than an alternating-current arc, some other means are necessary of breaking the arc after a discharge has taken place.

Arresters with moving parts have been made for this purpose, but it will readily be appreciated that an arrester with moving parts is more of a menace than a protection, as many lightning discharges are immediately repeated over approximately the same course, and in this case the moving element is in the wrong position to take the second discharge, in which case the apparatus suffers. In addition to this, it has been found that the enormously high potentials, due to lightning, cause arcing and disintegration, so that the moving elements refuse to assume their normal positions of rest after a number of discharges.

After exhaustive tests in the laboratory and under practical operation the magnetic blow-out has been found to give most excellent satisfaction under all conditions, and the most satisfactory form of direct-current arrester is one consisting of a single spark-gap with sufficient resistance in series to shunt a portion of the dynamic current around the coil, so as to cause a strong magnetic field about the gap. The lightning discharge passes directly through the resistance and the spark-gap to the ground and the strong field immediately blows out the dynamic arc which follows, thus preventing damage to the arrester and to the apparatus.

In the installation of lightning arresters it is very undesirable to endeavor to effect a saving by cutting down the expenses connected with making proper ground connections, as fully 75 per cent. of lightning arrester troubles can be traced directly to this source. The connections from the line to the arrester and from the arrester to the ground should be as free from angles and bends as possible, and where turns are absolutely necessary the wire should never be bent at an angle, but in a curve of long radius; care should be taken that no inductive loops are formed by the complete arrester and its connections.

When the use of an iron pipe at the foot of a pole is considered advisable for the protection of the ground wire, a plug should be put in the top of the iron pipe and the wire soldered to it; otherwise the reactance of the ground wire surrounded by the iron pipe will impede the discharge.

Copper should be used for the ground, thick enough to prevent wasting away and having at least four square feet surface. The ground wire, which should not be less than 3/8 in. diameter in cross section and preferably in flexible strip form, must be carefully soldered and riveted to this plate, the joint covered with asphaltum, and the plate then buried in powdered coke in soil which is always damp.

Dry, sandy soil should be kept wet by artificial means if this is the only soil available for the ground connection, and it is advisable to dip several trenches radiating out 50 ft. from the main ground wire, in which ground wires are buried so as to get a large surface for the dissipation of the discharges. Where plates are buried in streams of running water or dead water, they should be buried in the mud along the bank in preference to merely laying them in the streams; and streams with rocky bottoms are to be avoided unless as a last resort. Where there are metal flumes, pipes or rails, it is advisable to rivet and solder the ground wires to them in addition to the connections to the copper plates, and when rails are utilized they should be thoroughly grounded.

In view of the fact that it is advisable occasionally to examine the underground connections to see that they are in proper condition, it seems advisable when the ground plates are installed to lay out exact plans of the locations of the plates, ground wires and joints, with slight descriptions of the same, so that at any future time the data may be referred to.

Revived Electrical Prosperity in Germany.

In the course of a report on returning trade prosperity in Germany, U. S. Consul-General Mason Says: "At length, after two years of anxious waiting and hoping, the crises in German industrial values which began in the spring of 1901 is definitely past, and a general recovery has not only begun, but has progressed so far as to have all the outward indications of permanence. To what extent the values of the prosperous period which preceded the collapse have been regained will be illustrated by the following table, which shows the market values of certain standard German industrial stocks on the 17th of April, 1900, when the general prosperity was at its height; on the 26th of September, 1901, when the depth of depression had been reached; on the last day of 1902, when recovery had definitely begun; and on the 20th of the present month, when the effects of returning activity had become manifest in the values of industrial securities. The exhibit includes electrical manufacturers, iron and steel works, iron ore and coal mines, and the Great Berlin Street Railway Company.

Company.	April 17, 1900.	Sept. 26, 1901.	Dec. 31, 1902.	Nov. 20, 1903.
General Electric Company	253.90	169.50	180.75	220.00
Siemens & Halske	176.00	145.00	120.10	140.00
Schuckert Electric Company	216.40	100.00	79.50	112.50
Electrical Enterprise Company	150.25	91.30	84.60	105.00
Electric Light and Power Company ..	114.25	96.75	93.75	109.75
Great Berlin Street Railway Company.	232.75	194.10	200.50	204.75

These companies may be taken as representative of the electrical industries of Germany. The foregoing comparison shows that while not one of them has recovered—in respect to the open-market value of its shares—the high-pitched prosperity of the early months of 1900, all have recovered in an important degree from the depressed prices of September, 1901, and each one now rules from 10 to 50 points higher than it did at the close of 1902.

An important element has been the fact that several of the leading electrical manufacturing companies—which have recently combined to avoid competition—have secured some important contracts for lighting and power plants, street railway installations, etc., in foreign countries, notably Mexico and South America. At a recent meeting of representatives from all the electrical manufacturing companies, it was found that they were, almost without exception, running on full time and with orders booked that will keep them occupied for several months to come. Many of these orders have been taken at what would seem in America low prices, but the German electrical industry is enormously developed, is equipped with up-to-date machinery, has an abundant supply of cheap, docile, skilled labor, and can turn out electrical machinery, cables, and all that class of work at minimum cost.

The Arnold Electro-Pneumatic Railway System as Employed on the Lansing, St. Johns and St. Louis Railway.

By B. J. Arnold.

As many of your readers know, I have persistently advocated the use of the alternating current directly in the motors for electric railways for several years (see *Transactions* American Institute of Electrical Engineers' joint meeting with the British Institution of Electrical Engineers, Paris, August 16, 1900; Niagara Falls Convention, August 24, 1901; Great Barrington, Mass., June 19, 1902, and New York, September 26, 1902). By referring to the discussions which took place at these meetings and to the technical papers, it will be found that there were few, if any other advocates, in this country of the alternating-current for railway work until recently, and that those who supported it abroad advocated the use of three-phase currents until within the last few months. Since my announcement of the principles of my system before the Great Barrington Convention, the development of the single-phase alternating-current railway motor has made remarkable strides, both in this country and abroad, and while at that time it had few friends the development has been such since, that it now seems destined to take its place as the leading railway motor, thereby effecting a revolution in electric railway work.

Many of your readers also know that, since announcing the principles of my system before the Great Barrington Convention, I have refrained from giving out any further information regarding it, giving as my reasons therefor my desire to test the system thoroughly before making further public statements regarding it, and then to present a full and complete description of it, together with the results of its operation, in the form of a paper before the American Institute of Electrical Engineers. Consistently pursuing that policy I have conducted my experiments privately and at my own expense, and had so perfected my apparatus that I had hoped to be able to celebrate the incoming of the year 1904 with a public demonstration, over 20 miles of railroad, which would conclusively prove that the single-phase electric railway is not only operative but efficient, and less in first cost and operation than any system now in vogue, not meaning to imply thereby that the system which I have developed was necessarily the only system or the best system, for only time can prove the correctness or incorrectness of such statements, but that it was a system which would successfully do the work, and the system which was first developed and first to be put in actual operation upon the first electric railway in the world, especially built for single-phase alternating-current motor operation.

That I would have made a demonstration on January 1 was a certainty to me until December 18, when I learned by telegraph, while in New York, that the car houses, located at Lansing, Mich., of the road upon which I had been experimenting, were completely consumed by fire at 4 o'clock that morning. The fire apparently originated from a stove in the engine house, and was communicated so rapidly to the car houses that it destroyed a steam locomotive and two new cars built for my system, as well as my experimental locomotive, thus leaving me unable to make the demonstrations as I had planned. In view of the fact, however, that the single-phase electric railway is now receiving so much attention at the hands of engineers and inventors in many parts of the world, and that I believe that the year 1904 will be an epoch-making one, marking the revolution from the direct-current to the alternating motor for railway work, as well as the beginning, on a large scale, of the displacement of the steam locomotive on railways by the use of a substantial form of overhead construction rather than the third rail, and from the further fact that I cannot get another machine ready in the near future, I have concluded that I will give to the technical press a record of my work up to the present time, in order that it, and the system which I have developed, may be properly weighed in comparison with the work and systems of others, leaving the more complete description of the system and the results of its operation to be presented at a later date before the American Institute of Electrical Engineers.

In January, 1900, I rode over the country between Lansing and St. Louis, Mich., a distance of about 60 miles, with a party of gentlemen who desired to build an electric road between these points. This trip resulted in my advising them that the territory was such that I believed the road should be built as economically as possible, and, inasmuch as they desired me to assist financially in its construction, I told them I would do so provided I was allowed to construct the road in accordance with certain ideas that I then had in mind, for by such construction the first cost of the road could be kept sufficiently low to warrant its construction, and that if it were built on any one of the systems, standard at that time, the advisability of building it was questionable. The result was that on April 23, 1900, a contract was entered into wherein I undertook to build and equip the road. Engineers were at once placed in the field to locate it, and after the plans were sufficiently completed the grading, bridging and track work of 20 miles of the road followed, and this much of the road was completed, to such an extent, that steam trains were put in regular operation over it about November 15, 1901.

For financial reasons the completion of the road was delayed, and, in the meantime, the development of my system was taking place and the parts being perfected in different offices and shops.

Since it was my intention to experiment with pressure as high as 15,000 volts on the working conductor, all of the line material had to be specially designed, but the work progressed to such an extent that the overhead and line work of 20 miles of road was practically completed and ready for operation about December 15, 1902, and the power installed, so that experiments began in March, 1903. On June 15, 1903, two trips were made, each about 3 miles long, with my first experimental machine, shown in Fig. 8 of the accompanying description. On the first trip seven persons were carried, and on the second trip thirteen persons were aboard,

The result of the experiments with the first motor proved the correctness of the theory and that the machine would work. Inasmuch as it consisted of but one somewhat crude electropneumatic motor, it was impossible to get full and efficient tests of the system, and it was thought best to conduct no further experiments until a complete new double equipped truck could be perfected. Not being connected with manufacturing establishments I have been compelled to develop this system under trying circumstances, necessitating the construction of parts in different shops and assembling them at far distant points with crude facilities. This fact, combined with the financial difficulties that have arisen, and the necessity of my having to give the main part of my attention to other matters, have been the causes of the delay in completing the road and the system.

A new double-motor equipment, in the form of a locomotive, was finally built and brought to perfect working condition on the evening of December 17, and it was this locomotive with the necessary instruments for testing purposes that was destroyed by fire the following morning. Since it is going to be impracticable for me to get a new one constructed for some time, I have thought best to state the facts as outlined above, and give to the technical press a description of the apparatus and the road, reluctantly omitting the records of operation and the tests which I had hoped to have accompany any future statements I made, but which, through "the irony of fate," must now be left for the future. Below will be found some particulars of the road and system:

ROADBED AND TRACK.

The Lansing, St. Johns & St. Louis Railway was originally projected to extend from Lansing, the capital of Michigan, northward through St. Johns, Alma and St. Louis, a distance of about 60 miles, but up to the present time only that portion extending from Lansing to St. Johns, a distance of 20 miles, has been constructed.

This road was built in accordance with steam railroad practice, with easy grades and curves, so that steam locomotives could be operated over it until such time as electrical equipment could be put upon it: the idea being to complete the road in such a manner that it could be utilized for both freight and passenger service, and thus secure all the business available from the territory through which it passes.

The road is equipped with 67-lb. T-rail, laid on ties spaced 2 ft. apart between centres, and as alternating high-tension current was to be used but one of these rails was bonded with 38-in. 0000 bonds, extending entirely around the splicebars.

Since it was impossible to secure rails from the rail manufacturers in time, rails and splice bars were secured from one of the leading steam railways, and this necessitated the adoption of a supported joint and a long bond, as there was not room under the splice bars for concealed bonds.

The road as at present constructed between Lansing and St. John has no grades exceeding 1 per cent, and no curves exceeding 7 degs., except in the cities themselves, where the terminals of the road run over the streets and make such curves as ordinary street cars make, the minimum radius being 50 ft. At each city a terminal was planned so that all freight would be diverted to connecting steam roads, thus making it unnecessary for the freight service to pass over the city streets or curves.

At the Lansing end it was necessary to pass over the steam railway tracks of the Pere Marquette Railroad, and this necessitated the construction of a bridge with pile approaches. The grade, as approached from the Lansing end, being 4 per cent for a distance of about 700 ft., and after passing over the bridge the descending grade is 2.3 per cent for about 500 ft. At the St. Johns end there is a grade on the principal street of the town averaging about 2 per cent for about 1,500 ft.

OVERHEAD CONSTRUCTION.

Considerable care was taken in planning a suitable insulator for carrying the trolley wire, and Fig. 1 shows the construction of the annealed glass insulator used.

Fig. 2 shows a typical arrangement of the straight line overhead construction, and it will be noticed that wood is used for the pole, cross-arm and braces, and that the insulator is supported by means of a short span wire from iron brackets secured to the wooden cross-arm. This construction insured a high insulation at a low first cost, the entire line having been constructed for but a slightly increased expense over the cost of standard construction, and at the same time so built that in case of failure of the alternating-motor system the standard direct-current motor system could be put into service without changing any parts. Even holes for the pins for carrying the extra feeders which would be required were provided, as shown.

It will thus be seen that the line and track work were constructed in such a manner that no expense was incurred for any parts which would not be required for standard construction in case it became necessary to ultimately adopt the standard direct-current motor system; the entire idea in the construction of the road being to save first cost and to invest all that was invested in such a manner that all material purchased would be utilized in case either system were adopted, and should the alternating system prove successful the additional investment for a direct-current motor system need not then be incurred.

The working conductor was placed 22 ft. above the top of the rails in order that trainmen, when standing upon the tops of the freight cars going over the road, could not come in contact with the working conductor.

It was planned to operate the entire road from a single 00 trolley wire, and with one rail bonded as hereinbefore mentioned; this amount of copper being sufficient to operate four 40-ton cars at an average speed of 30 m. p. h., with power house located 1½ miles from one end of the line, and operating with from 6,000 volts to 10,000 volts on the working conductor.

The power house is located at one end of the line, owing to the electric company, from which power is purchased by the railroad, having a water power at this point. Current is transmitted to the nearest end of the line over two No. 3 wires. The power is furnished from a 300-kw rotary converter, generating at 380 volts at 25 cycles, the energy from which is stepped up to the working pressure of the line. It was the intention, after experimenting a sufficient length of time to determine the best voltage for the working conductor to have the generators for the permanent plant constructed so as to generate at this determined voltage, and it was for this reason that a temporary rotary converter was first installed to conduct the experiments with.

During the preliminary experimental period upon the apparatus, hereinafter described, all power was transmitted from the above-mentioned power house to a point about 2 miles distant, where were located the car houses in which the preliminary experiments were made.

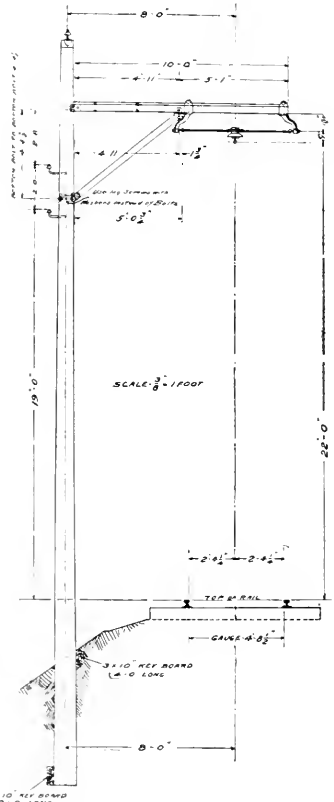

FIG. 1.—TYPICAL STRAIGHT LINE OVERHEAD CONSTRUCTION.

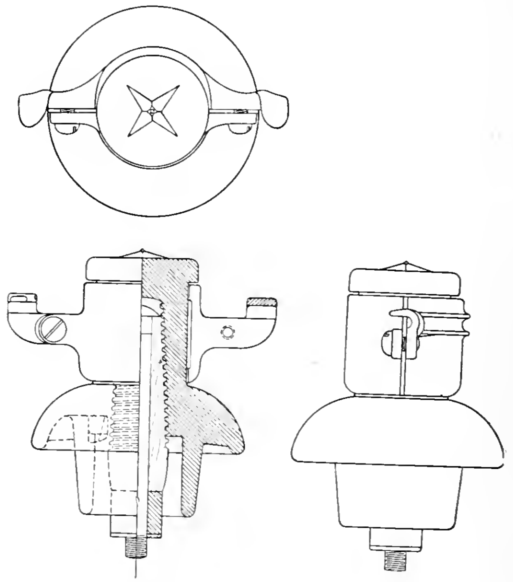

FIG. 2.—SPECIAL INSULATOR USED.

The conditions under which the first application of the system took place having thus been set forth, it may be well, in order to get clearly before the reader, the principles on which the system is based, to quote here the statements made by myself before the Great Barrington Convention on June 19, 1902, as follows:

"The principles underlying the system I advocate, and which I call an electro-pneumatic system, are as follows:

"1. A single-phase or multi-phase motor, mounted directly upon the car, designed for the average power required by the car, and running continuously at a constant speed and a constant load, and, therefore, at maximum efficiency.

"2. Instead of stopping and starting this motor and dissipating the energy through resistances, as is customary with all other systems known to me, I control the speed of the car by retarding or accelerating the parts usually known as the rotor and stator of the motor, by means of compressed air, in such a manner that I save a portion of the energy which is ordinarily dissipated through resistances, and store it to assist in starting the car, helping over grades, for use in switching purposes and for the operation of the brakes.

"3. By this method of control I secure an infinite number of speeds from zero to the maximum speed of the car, which may or may not be at the synchronous speed of the motor, for with the air-controlling mechanism working compressing, the speeds below synchronism are maintained, and by reversing the direction of the air through the controller speeds above synchronism may be attained for reasonable distances. This feature gives to the alternating-current motor the element absolutely essential for practical railway work, for it permits a car or train to ascend a grade at any speed with the motor working at its maximum efficiency and imparting its full torque to the car. When descending the grade the motor may utilize its full power drawn from the line in compressing air, or it may be used to compress air with the stored energy of the train, thereby acting as a brake.

"4. By virtue of the air storage feature each car becomes an independent unit, and capable, in case of loss of current from the line, of running a reasonable distance without contact with the working conductor. This feature will enable a car to work on a high-tension trolley wire or active conductor over private right of way, and allow the active conductor to be stopped where the private right of way ceases, and the car to proceed through a city or town on any tracks, whether electrically equipped or not, until it reaches the outskirts of the city or town, where it can take up the working conductor again on private right of way. This feature is also valuable in switching work, for each car being independent it can leave the main line track and operate over switches or sidings without complicating the yards with additional overhead or third-rail conductors, thus necessitating through-line conductors over main-line track or tracks only.

"5. Since a single-phase motor can be used the motors can be supplied with current from a single overhead wire or third rail, and with a single-rail return circuit, thus permitting the overhead construction, or third-rail construction, to conform to the standard of to-day, except that a much higher working voltage can be used, provided the insulation is taken care of. Furthermore, in steam railway work this system, by virtue of its single-phase features, will only require the use of one of the track rails for the return circuit, thus leaving the other rail for the use of the signal system, which, up to the present time, does not seem to have been satisfactorily solved without the use of one of the track rails.

"6. The current will be taken from the working conductor at any voltage up to the limit of the insulation, and in case this voltage is high (I am building my line for 15,000 volts), a static transformer will be carried upon each car and the pressure reduced from the line voltage to the voltage of the motor, which, in the case under construction, is designed for 200 volts. Where it is unnecessary to utilize so high a line pressure the motor may be designed for the working voltage, and the current fed directly from the working conductor into the motor, thus eliminating the static transformer. When a high-voltage working conductor and static transformer is used, and it is thought advisable to use a working conductor through cities or towns, this working conductor will be supplied with energy through a stationary transformer at each city limit, thus making the working conductor through the cities or towns safe.

"7. By virtue of the speed of the motor and its constant load, either when the car is in motion or when it is standing still, and the motor is compressing air, the variable load now customary in electric railway power plants is eliminated, and the power station works at practically a constant load, thereby eliminating a large part of the investment at present requisite in power station and line construction. Furthermore, by virtue of the air storage feature each car, in the particular apparatus I have designed, is capable at any time when current is on the working conductor, of delivering to the car wheels a much greater torque in proportion to the capacity of the motor than is possible with any electrical system known to-day.

"I believe that by the adoption of this system the following results will be accomplished:

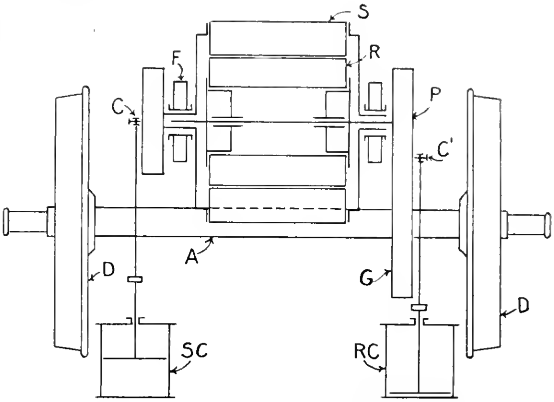
"1. The entire elimination of the present standard system of rotary converter substation plant, together with the maintenance thereon, and the cost of the necessary attendants.

"2. The absorbing and rendering available for useful work in starting, or otherwise, a large percentage of the energy stored in the moving mass, which, under the present methods of operation, is dissipated at the brake-shoes.

"3. A large reduction in the first cost of electrically equipping long-distance railroads, thereby making it feasible, from an engineering and business standpoint, to equip many roads which cannot now be shown advisable, thus opening up the steam railway field to the industry in which we are now engaged."

The following description will explain more in detail the application of the principles of the system and the mechanism of its working parts:

Fig. 3 represents diagrammatically the working parts of one form



R—Rotor.
S—Stator.
F—Frame.

RC—Rotor Cylinder.
SC—Stator Cylinder.
C—Crank of Stator.
C'—Crank of Rotor.

FIG. 3.—DIAGRAMMATIC ARRANGEMENT OF ELECTRO-PNEUMATIC MOTOR.

of the system. The rotor *R* of a single-phase induction motor is geared to the axle of the car, and by means of crank pin, *C'*, secured in pinion *P*, also drives the compressor cylinder *R C*, while stator *S* can freely revolve around the rotor and drive by means of crank pin *C* the compressor cylinder *S C*. Both cylinders are piped to air reservoirs located under the car, and are also provided with suitable valve manipulated from a single controller on the car platform for making them perform their various functions, thus the entire regulation of the speed and power of the car are controlled by the air cylinders, and no other regulating devices are necessary. The cylinder valves are electrically operated, which makes it possible for each cylinder, when driven by the electric motor, to compress air into the tanks, and when operated by compressed air to furnish mechanical energy for moving the car. When, for instance, the cylinder is compressing air the valves work like inlet and outlet poppet valves of a common air pump, while on the other hand if the cylinders are supplied with compressed air each valve is operated electrically by a pilot solenoid connected with the valve seat in such a manner that the energy for moving the valve is supplied by the compressed air, thereby making the valve practically self-actuating. The time of operation of the valves is controlled by a series of collector rings revolving with the engine shaft, and their regular operation is interrupted and varied to suit the requirements by means of the motorman's controller.

When a rotary or turbine type of air engine is used all of the above valves and reciprocating parts are eliminated and the entire controlling mechanism consists of two air valves, operated from a single engineer's valve, which may be located upon the platform of the car or in the cab of the locomotive, and so arranged that one or more units may be operated from the platform of the cab of any unit without the necessity of connecting wires between the units.

Since the motor may be of the simplest types of induction motor without a commutator, and the system does not require the manipulation or breaking of the main current the motor may be designed for any working voltage, and be of any type which will maintain a constant speed when provided with a constant load. This eliminates the necessity of all step-down transformers, resistances or other regulating devices and confines the current to the motors themselves, and as these are below the car floor the danger from the current is reduced to the minimum.

At the same time the air cylinders, in addition to performing all the functions of speed control, give to the machine the independent unit element, and the ability to store the kinetic energy of the train in stopping and utilizing it in starting. On account of these and other features the electric motors of this system can be much smaller in capacity when rated as continuous working motors, than those of other systems not possessing this equalizing load feature, and the capacity of the power house and line can be reduced to about one-half of what would be required with systems where the fluctuating starting loads of the cars are transmitted back to the power house.

In order to better understand the different operations of the system, Fig. 4, showing a speed diagram, has been prepared, in which,

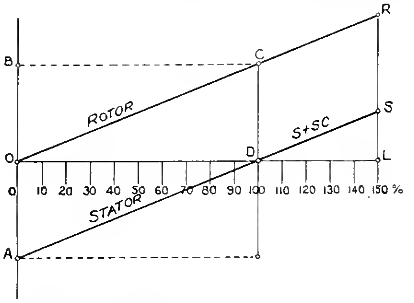

FIG. 4.—DIAGRAMMATIC REPRESENTATION OF OPERATION.

on the axis of abscisse, *O D L*, are represented the different car speeds in per cent of the synchronous motor speed, while the coordinate axis, *A O B*, represents the rotor and stator speeds corresponding to the car speeds shown.

The operation of the car may be divided into the following periods:

1. STANDING IN THE STATION.

Referring to Fig. 3 the rotor *R* is standing still, while the stator *S* runs with full synchronous speed. The stator is then transferring the full energy of the electric motor through crank *C* to the compressor cylinder *S C*, which energy is being delivered in form of compressed air into the air reservoir.

Since the relative velocity between the stator and the rotor is, under all conditions of operation, constant, the speed curves of stator and rotor may be represented by two parallel lines, *O C R* and *A D S* in Fig. 4. The origin *O* of the given co-ordinate system represents the period of rest of the car, and, therefore, indicates zero rotor speed and full stator speed in a negative or downward direction, as the stator is now revolving in the opposite direction from that which the rotor must revolve to drive the car forward.

Let it be further assumed that for an instant *O A* equals the active torque of the stator, then it will be easily understood that *O B*, which equals *O A*, represents the reactive torque of the rotor exerted on the car axle, meaning that if the car is free to move the reactive torque can be used advantageously for the starting and acceleration of the car.

When the car is standing in a station it is held at rest by moving the controller to such a position that the outlet pipe from rotor cylinder *R C* is throttled, thereby increasing the pressure behind the piston to such an extent that it overcomes the effort of the rotor *R* to revolve, thus tending to cause the stator *S* to revolve and at the same time holds the car at rest without the use of wheel brakes.

2. STARTING AND ACCELERATING.

To start the car the air cushion behind the piston of *R C* is removed, and the air, which is being compressed by cylinder *S C*, supplemented by the stored air from the tanks, is admitted to cylinder *R C*, with the controller at the position of maximum cut-off. The rotor then begins to revolve, and as it accelerates the stator slows down by exactly the same amount that the rotor has increased its speed, and as the rotor and car speed increase the controller is gradually moved to a smaller percentage of cut-off, until the car speed corresponds to the full synchronous speed of the motor, at which time the stator comes to rest.

During this period of acceleration the air compressed by cylinder *S C*, instead of being delivered to the tanks to lose its heat, is delivered, hot, directly to the rotor cylinders, thus greatly increasing the efficiency of the combination, as the heat usually lost in air systems is utilized, and the advantages of heated air gained without a reheater, and as the pressure used is low many of the ordinary difficulties in the use of compressed air disappear. If the rate of acceleration is such that cylinder *R C* uses all of the air supplied by cylinder *S C* no exhaust to the atmosphere from cylinder *R C* takes place.

Referring now to Fig. 4, which graphically represents this process, since the electric motor runs always at a constant speed and a constant load, it has a constant torque, and, therefore, the distance between lines *O C R* and *A D S* may be considered as representing the energy delivered by the electric motor.

The length of any ordinate extending from *O D* to *O C* represents the proportionate amount of energy derived from the electric motor, which is applied directly through pinion *P* and gear *G* of Fig. 3 to the propulsion of the car, while the corresponding ordinate extending below *O D* to *A D*, represents the proportionate amount of the energy of the electric motor, which is absorbed in compressing air through cylinder *S C*, which energy, in the form of air, is immediately transferred to cylinder *R C*, and is utilized in accelerating the car.

In practice, however, since there will be a loss in transferring the energy from electrical energy to energy in the form of compressed air and back again into mechanical energy, this loss, whatever it may be, must be drawn from the storage tanks, and the requisite amount of air from these tanks supplied to rotor cylinder, *R C*, in order to maintain the full power of the electric motor upon the car axle during the period of acceleration. Should it be desired to accelerate at a greater rate than the full power of the electric motor is capable of giving to the car the additional energy may be supplied in the form of air from the storage tanks through cylinder *R C*, thus increasing the total energy given to the car during acceleration, in which case this total power would be represented for any given instant by a point above line *B C*.

3. FULL SPEED.

When the rotor has reached full synchronous speed, by the previous operation, this speed can be maintained by moving the controller to another position, which will throttle the outlet pipe of cylinder *S C* until the reaction due to the pressure behind the piston equals the full capacity of the electric motor. An overload or underload may be placed upon the motor by varying this pressure, but under normal conditions of operation cylinder *S C* is provided with an automatic valve, which keeps a constant pressure behind its piston, thus maintaining an absolutely constant load upon the electric motor, and consequently a uniform demand of electrical energy from the line. This uniform load is represented by the parallel lines *O C R* and *A D S* of Fig. 4.

With the controller set at full-speed position the inlet valves of rotor cylinder *R C* are held open and the piston runs free and the electric motor now gives its full power to the car axle, and the stator and its air mechanism will remain at rest as long as the car runs at the speed corresponding to the synchronous speed of the motor.

4. SPEED VARIATIONS.

There are usually certain places on any road where high rates of speed can be maintained for short distances, and as these speeds might be higher than the synchronous speed for which the motor was designed they are provided for as follows:

Assuming that the car is running at synchronous speed the controller may be moved to such a position that the valves of stator cylinder *S C* operate in such a manner as to cause it to act as an engine and revolve stator *S* in the same direction as rotor *R* is revolving. This now causes, owing to the constantly electrically maintained relative difference in speed between the stator and the rotor, an increase of speed of the rotor and car axle, due to the motor automatically working as a magnetic clutch, without mechanical contact, and if the resistance of the car or train is less than the capacity of the electric motor, the air necessary for revolving the stator can be obtained, hot, from the rotor cylinder *R C* without drawing from the tanks, and a speed above synchronism indirectly proportioned to the resistance of the train maintained indefinitely. When the resistance of the train is greater than the capacity of the electric motor speeds above synchronism can be obtained only by supply rotor cyl-

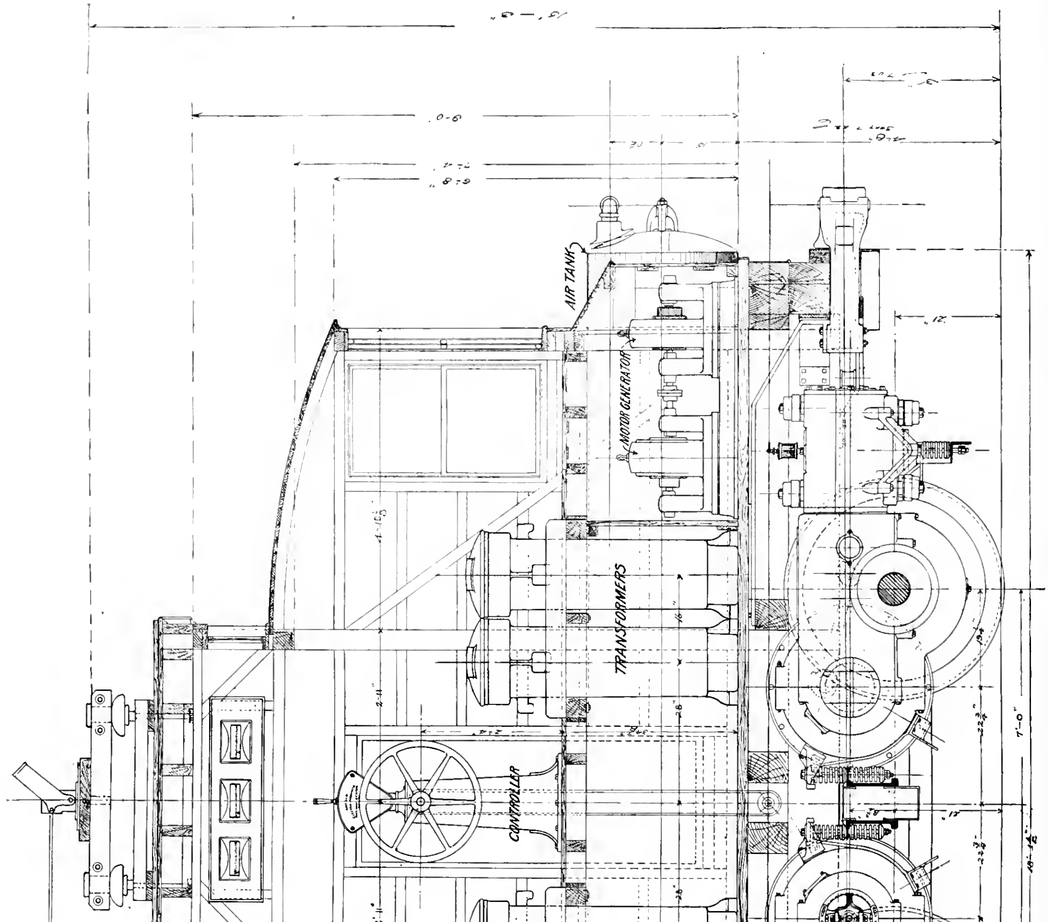

Fig. 12.—Longitudinal Section of Locomotive.

inder R C with stored air from the tanks, and can only be maintained for short distances, or until the storage capacity of the air reservoirs is exhausted. This condition corresponds to the spurts that can be made by a steam locomotive when working above the steaming capacity of the boilers. The distance from the line O D L to that portion of the line A D S above O D L in Fig. 4 represents, at any given speed, the proportionate amount of energy which must come from the tanks, and be supplied through cylinder S C, and the distance from D L to C R represents the total energy given to the car by the combined action of the electric motor and the stator cylinder when operating under these conditions.

The energy delivered to the car can be still farther increased by admitting air into rotor cylinder R C, and allowing it to work as an engine.

5. RETARDATION.

To bring the car or train to rest, instead of applying mechanical brakes to the wheels in the ordinary manner and thereby dissipating the entire stored energy of the car or train in the form of heat, this energy is saved in the form of compressed air, to assist in starting the car or train, by setting the controller in such a position that rotor cylinder R C compresses air and delivers it into the storage tanks. Any desired rate of retardation can be secured by throttling the delivery pipes from rotor cylinder R C, and in practice this pipe is provided with an automatic valve, which releases just before the slipping point of the wheels, thus allowing the motorman to brake as rapidly as he desires without liability of flattening the wheels. Supplemental wheel brakes are provided for emergency, but need not often be used, and the ordinary wear and tear on them is saved. When the car is again at rest the cycle of performance as above given is repeated for the next run.

6. REVERSING.

When it is desired to run the car backward for short distances the electric motor is not disturbed and the power is furnished by the rotor cylinder, R C, by reversing the action of the valves; but if it is desired to run backward for any great distance, the current is thrown off the motor, the stator engine reversed, and the stator brought to speed by the air, when the current is again thrown onto the motor, and the cycle of operation is the same as when running forward.

Fig. 5 represents the exterior of the electric motor, showing the cranks of the stator and rotor, also collector rings for operating the valves of the air cylinders when working as engines.

Fig. 6 shows an interior view of the stator of the motor with the flange removed, the rotor of the motor being of the standard squirrel cage induction type.

Figs. 7 and 8 show, mounted upon a track, two views of the first electropneumatic motor constructed, and upon which the first experiments were conducted, while Fig. 9 shows the same truck and motor placed underneath one of the care constructed for the system, the design of which is shown more clearly in Figs. 10 and 15.

Since the single motor represented in Figs. 7 and 8 was too small in capacity to propel so large a car, it was decided to experiment with an improvised locomotive, consisting of the truck and motor shown in Figs. 7 and 8, carrying suitable air tanks and transformers upon a temporary frame structure. This locomotive, shown in Fig. 9, was the one upon which the trial runs were made and passengers carried on June 15, 1902.

Figs. 16 and 14 show the end and side views of the new electro-pneumatic motor constructed after the preliminary experiments had been made on the first motor. For experimental purposes this truck was fitted up in the form of a locomotive, as shown in longitudinal and transverse section by Figs. 13 and 14, and it was this locomotive that was recently destroyed by fire. In order that the locomotive might operate as an independent air unit upon tracks not equipped with overhead electrical conductor, it was provided with a small storage battery and small motor generator for charging the batteries, and for operating the headlight. These auxiliaries are not necessary for the successful operation of the system, provided the locomotive can always be supplied with electric current from the working conductor, for then the valves can be made to operate from alternating current, and thus eliminate the use of motor-generator and batteries. When, however, it is desired to operate independently of the electric conductor these auxiliaries are necessary, and one set may supply an entire train. It will be seen that the locomotive is also provided with transformers, another auxiliary which is unnecessary in case the motors are designed for the voltage transmit-

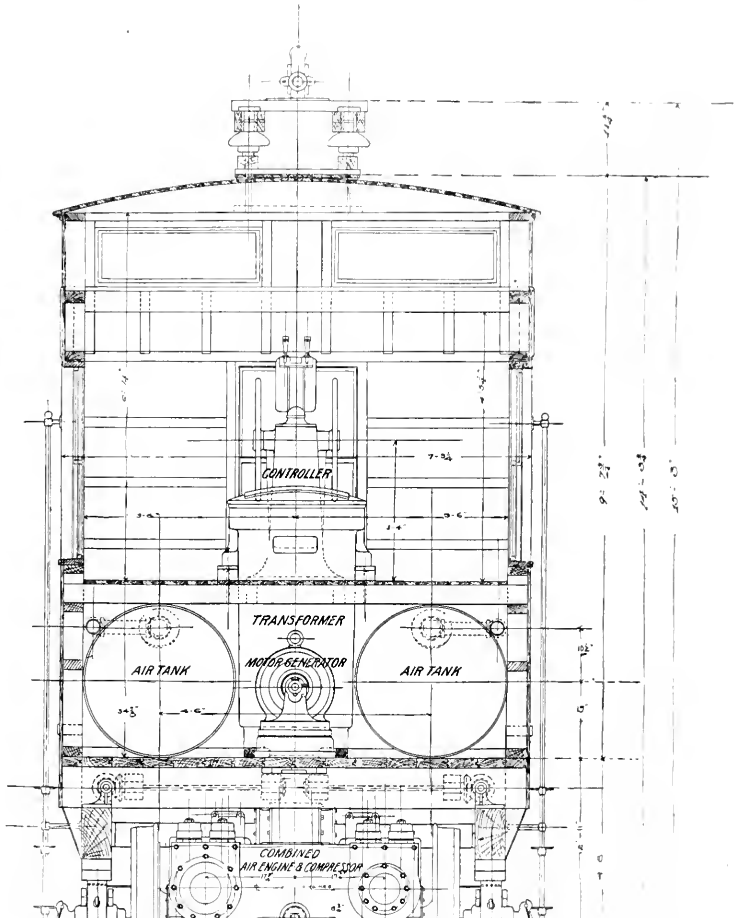

FIG. 13.—TRANSVERSE SECTION OF LOCOMOTIVE.

ted over the working conductor, but in this case transformers were used because the manufacturer of the motors could not be induced at the time they were purchased to build a high-tension motor for railway work, consequently the parts of a standard motor were utilized,

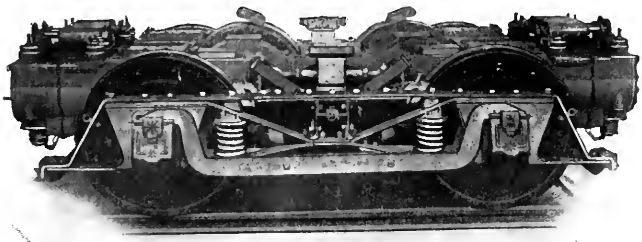

FIG. 14.—SIDE VIEW OF LATEST MOTOR EQUIPMENT WITH TRUCK.

and a pressure of 200 volts adopted for the motors, as this was the most economical voltage that could be used with the particular parts selected. This locomotive was provided with all necessary testing instruments, and had been operated in the car houses for some time, and found to perform all its functions successfully, and would have been placed on the road, and experiments with it would now be in process had it not been destroyed. All that remains of it is shown

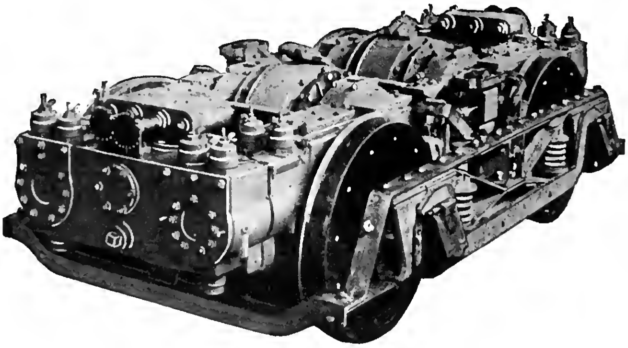

FIG. 16.—END VIEW OF LATEST DOUBLE MOTOR EQUIPMENT WITH TRUCK.

in Fig. 11, taken from a photograph of the site, the lumber shown having been carried to the site after the fire to shelter the machine with.

The Curies and Radium.

In a recent article in the New York *Independent*, about the Curies, Mme. Beinstock tells of the trials which the young French couple had before they gained fame. At the start the material situation of the young couple was not very bright. Neither had any fortune, and with the few thousand francs which they earned it was no easy task to make both ends meet at the close of the year in such an expensive city as Paris. So they went out into the suburbs of the great capital and established themselves in the little town of Bourg-la-Reine, distant two or three miles from the walls; and in order to save the railway fare, husband and wife, in all weathers and at all hours, made the journey by bicycle from their modest lodgings to their laboratory in the dingy old Rue Lhomond, where they have made their important discoveries. When it is known that the road from Bourg-la-Reine to Paris is block paved much of the distance and encumbered in many ways, these goings and comings on "the wheel" were not holiday rides, especially in the case of the frail young wife.

Soon a child came to the struggling couple. The little daughter is now seven years old, in good health, full of life and tenderly cared for by the loving mother. So Mme. Curie is not only a scientist, whose name is well known throughout the world, but a model wife and mother, another and most striking example of the fact that the new woman does not differ in this respect materially from her sister.

The prize of 100,000 francs ($20,000) placed at the disposal of the Parisian press syndicate by M. Osiris has been divided between Mme. Curie, to whom 60,000 francs ($12,000) has been allotted, to enable her to continue her researches as to radium, and M. Branly, who received 40,000 francs ($8,000) for his discovery of the conductibility and non-conductibility of filings under the influence of the Hertzian waves, which rendered wireless telegraphy possible.

Mme. Curie has contributed an interesting article to the January *Century Magazine*, in which she discusses the subject of radium and makes a number of interesting and important statements and deductions based upon her own experiments and observations. The article was in all probability written several weeks ago, since which time, as our readers know, a good deal of new work has been done in the field; but it is none the less well worth reading. Prof. Ernest Merritt, of Cornell University, has also in the same issue an article on the subject, which will also enlighten and instruct the general public.

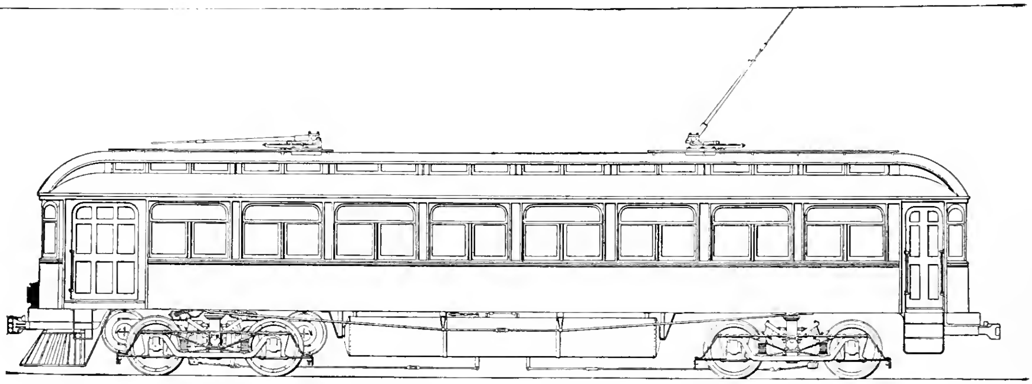

FIG. 15.—DRAWING OF COMPLETE CAR.

Water Power Electrical Generating Plant at Riva, Tyrol.

By FRANZ KOSTER.

RIVA, a city on Garda Lake, in the Tyrol, and much frequented by tourists, possesses a water power electrical generating plant of unusual interest in view of the fact that the total population served, including that of Varone and St. Giacomo, neighboring towns, is less than 8,000. When it was decided to put down a plant several water powers presented themselves for consideration. The city is within easy distance of the Albole, a small stream with a fall of 650 ft., and the Varone, with a fall of 327 ft. As these, however, were already largely occupied for commercial and supply purposes, it was determined to use the Ponale, which, though having a fall of only 200 ft., is larger and more available and from which may be utilized a water power of 2,000 hp.

The station has been erected in two parts; the second, just finished, having been commenced upon the completion of the first part. A third portion will be erected as soon as the necessity for the power arises. The portion first erected contains dynamos and turbines of double the power of those of the first part. The plant was designed and erected by the Maschinenfabrik Oerlikon, of Zurich, Switzerland.

The Ponale, which has a minimum flow of 500 gallons per second, connects Lago di Ledro, a natural reservoir fed from springs, with Lago di Garda, 2,000 ft. lower and some 10.5 miles away. In addition the Ponale is fed on its course by many small tributary springs. The principal power reservoir lies 285 ft. above the level of the Lago di Garda and is firmly constructed of iron and masonry. To this reservoir from a convenient point on the Ponale the water is fed, first through an open canal 115 ft. long, 6.56 ft. deep and 7.25 ft. wide, then through a tunnel through solid rock 787 ft. long, then in an open canal 26.25 ft. long, and finally through another tunnel 50.4 ft. long. These tunnels, which can be entered for inspection and open canals, were required on account of the necessity of carrying the water across ravines and through the mountain "Val de Ledro." From the reservoir the water finds egress into the penstock, which has on its water inlet a strainer-head over which is fitted a removable finely-perforated hood. At one side provision is made for the overflow and a drainage canal.

The penstock leading to the central station is 557 ft. long and of riveted steel plates with a diameter of 2.4 ft.; it is above ground through its entire length, lying on a steep rocky slope and supported on masonry and steel piers built on the native rock. Arrangement is made for the erection of two other similar penstocks when necessity arises, parallel to the present one and on the same foundations. The penstock supports are constructed to allow such slight movement as is caused by expansion. Two expansion joints have been inserted for the necessary purpose. At the foot of the penstock, which is

FIG. 2.—RIVA POWER STATION.

strongly constructed, a branching occurs, leading through a canal blasted from solid rock to the portion of the power house first erected. One branch of the penstock leads to the three turbines first installed, while the other leads to the two turbines in the next room. These branches are provided with double safety and discharge sliding valves, and the turbines may be shut off by by-pass sliding valves.

The power house, which is, as stated, in the immediate vicinity of the Ponale Falls, is 2.17 miles from Riva, and lies 165 feet above the level of the Lago di Garda. It is picturesquely situated on the mountainous slope of the "Val de Ledro." The building is of brick and rough stone work with a roof frame of iron and wood carrying a terra cotta roof. The main floor of the power house is divided into two parts. The original portion contains a room for the three 150-hp. turbines and dynamos, and four rooms for the occupancy of those in charge of the operation of the plant; in the addition is a machine room for the 300-hp generators and a room for apparatus.

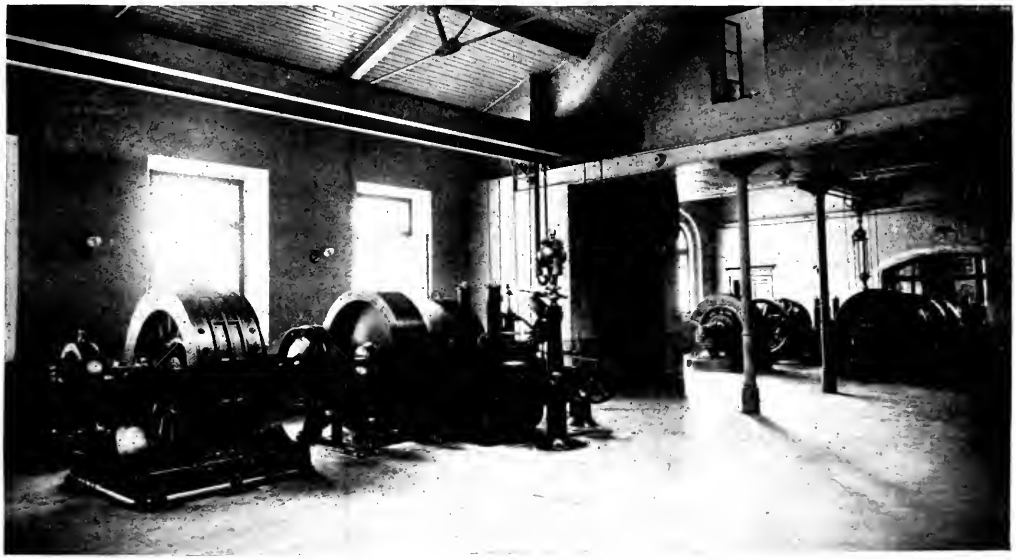

FIG. 1.—VIEW OF INTERIOR OF RIVA STATION.

In the second floor is a room for employees. Each machine room is fitted with a hand-power crane of 5 tons capacity, and the rooms are lighted with incandescent lights. The floors are of substantial parquetry.

Two of the first group of 150-hp turbines are of the Girard type and the third turbine of this group is of the Rusch "spoon-wheel" type. The general arrangement of the three turbines, which make 300 r.p.m., is the same. Each turbine is regulated in two ways—by a hand wheel and by an automatic governor. The hand-wheel regulator through a worm and rack and pinion opens and closes the fly wheel on the shaft between the turbine and dynamo. The three first turbines develop a net efficiency at brake test with full gate of 81.33 per cent and with half gate 80.84 per cent. The 300-hp turbine with full gate shows 82 per cent.

In the portion first erected are three three-phase dynamos of 150 hp capacity each, and in the second a three-phase dynamo of 300 hp. All the dynamos, which are of Oerlikon type, and are connected with their turbines by insulating elastic couplings. The exciter dynamos are coupled direct with the generators.

The diameter between poles of the three first generators is 3 ft.

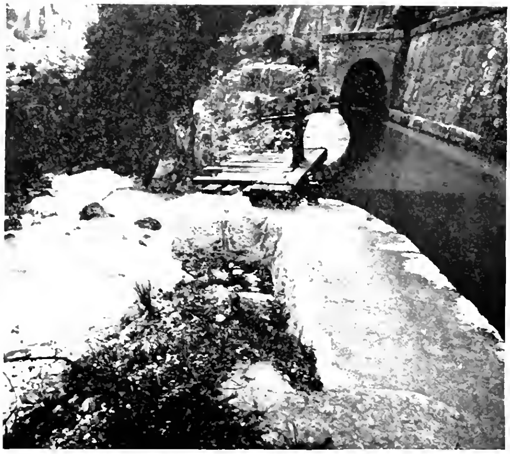

FIG. 3.—TUNNEL ENTRANCE.

FIG. 5.—WIRES ON CLIFF AT GARDA LAKE.

FIG. 4.—OPEN CANAL.

FIG. 6.—TRANSFORMER HOUSE.

gates. The rods of the automatic governor are connected with a hydraulic relay which acts upon a balance valve, thus regulating accordingly the amount of water admitted. The 300-hp turbine in the addition is of the Rusch type, the water being admitted through phosphor bronze passages. The blades of the turbines are Delta metal and interchangeable. Automatic regulation is accomplished by a balance valve responding to a sensitive centrifugal governor. For the prevention of sudden jars an oil dash pot is connected with rods to the governor. The turbine is also regulated by a hand-wheel regulator, through worm and rack and pinion. For each of the machine units the automatic regulation is supplemented by a $3\frac{1}{2}$ in., and the armature has a diameter of 3 ft. 3 in. They have 18 coils, two with 60 windings and the remainder with 59.5 windings of 1-6 in. wire. The 300-hp generator, also of the Oerlikon type, has an armature diameter of 4 ft. 3 in., and 21 coils which have 42 windings of 3-16-in. wire. The diameter of the revolving field is 4 ft. $2\frac{5}{8}$ in. The 14 exciter coils are connected in series and have 130 windings of $\frac{1}{4}$-in. wire.

The conductors pass in a masonry canal under the floor to the apparatus room, which is entirely cut off from the machine rooms. The switchboard is faced with white marble and is mounted on an iron frame work. It is divided into five panels, four at present being in use. In addition there is one general instrument panel. On each generator panel is a voltmeter, a four-pole switch, the starting and regulating apparatus, an exciter ammeter, and a phasing lamp. The general instrument panel carries a suspended voltmeter with switch for measuring the voltage of the three phases, and an ammeter for each phase.

In the switch room, the portion which adjoins the machine room and that which contains the four-pole high-tension switch are separated by a special partition of perforated iron. Above the four-

FIG. 7.—CANDELABRA WITH ARC AND INCANDESCENT LAMPS.

pole switch are the measuring transformers with safety fuses, while below rheostats and carbon cut-outs are arranged. On the other side of the aisle are the machine fuses, and on the north side of the room are eight wire fuses. Of these eight fuses, four are constantly under pressure, the remainder being held in reserve, so that in case of a burning out no interruption of service will occur.

The high-tension mains to Riva do not proceed by the most direct route, as that has been utilized for state telegraph wires. The city is reached by a circuitous route over the rough surface of the mountain side and along the cliffs of the Lago di Garda. The mains are carried on triangular iron brackets whose feet are imbedded in the

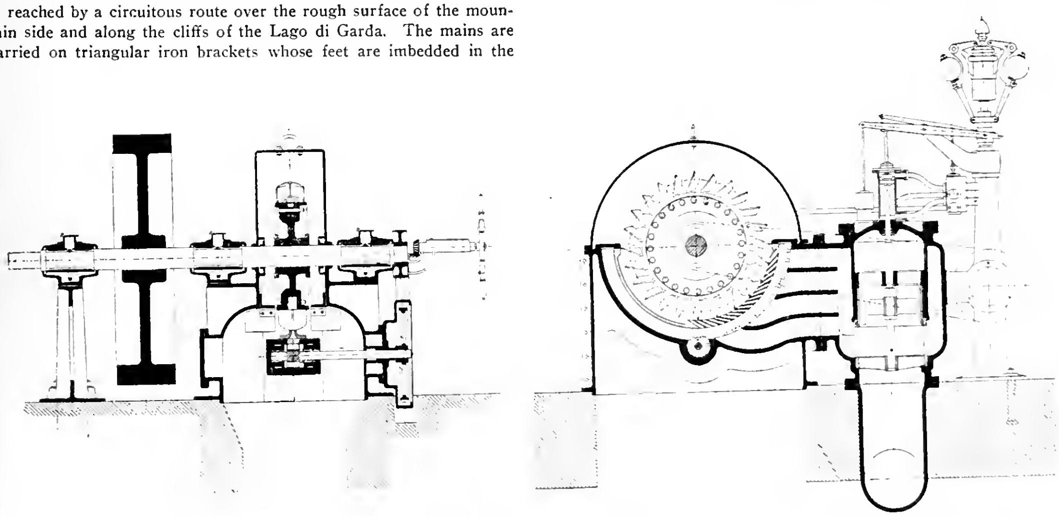

FIG. 9.—SECTIONS OF 300-HP TURBINE.

sides of precipices, and where permissible on iron and wood poles, of which, however, few are used. There are three wires and one neutral wire, each of hard drawn copper and ¼-in. diameter, and supported by double bell insulators. The high pressure mains enter at a tower from which an underground iron armored lead-covered cable of four wires passes to the transforming stations of the city. This cable is laid in sand under tile, covered by earth. At the two points where the high tension circuits leaves the city—one to Tarbole and the other to Varone—a tower again brings the mains above ground. A branch of the circuit to Varone leads to St. Giacomo. The length of the high-tension circuit in the city is 0.62 miles, the length to Tarbole is 3.5 miles, to Varone 1.9 miles and the branch to St. Giacomo 0.2 miles. These branches from Riva are supported

FIG. 8.—PENSTOCK.

on wooden poles and double bell insulators. The poles are 36 feet long and the tops are charred. The mains are fitted with horned lightning arresters.

The transformers are in fire-proof rooms, and each has a four-pole switch for the high-tension, and another one for low-tension, and one each in Tarbole and St. Giacomo. Low-tension wires are carried on wooden poles and brackets on the sides of houses, the wires used being from 3-16 in. to ⅜-in. diameter.

Arc lamps of 800 candle power swing from graceful candelabra or from suspension wires. They are 20 ft. above the street. The exposed incandescent lamps are also mounted on candelabra, on arms or on masts and are of 32 candle power. They are connected between one phase and the neutral wire and are in a 110-volt circuit. The power plant is in constant operation day and night except from noon to two o'clock on Sunday.

The Gas That Failed.

By Alton D. Adams.

THE fact that this year—1904—marks the twenty-fifth anniversary of the commercial introduction of the incandescent lamp would in itself render interesting a review of the growth of that illuminant as compared with gas. But special and peculiar interest is given to such a comparison by the remarkable fact just brought out by the United States Census office bulletin on central stations that such stations alone, regardless of isolated plants, have already overlapped gas in investment, labor employed, gross earnings and other vital features. An extraordinary chapter of industrial history is here revealed and one's thoughts go back involuntarily to the earliest days of the electric lighting art.

Those were years of conflict in the lighting field. Gas companies soon saw their incomes from street lamps dwindling, and their commercial business in danger. Rays of electric lamps had caught the popular eye and fancy. The illuminant that simulates daylight, requires no matches and operates without a flame was in rapidly growing demand. Two particular groups of persons stood ready to turn this situation to their own advantage. These were the purveyors of oil and the exploiters of patent gas processes. The hopes, the aims and the future gains of these persons were summed up in "water gas." All this was in the decade of 1880 to 1890.

Even at the beginning of this period water gas was not a new product. Before Brush gave the electric arc commercial importance, before Edison and his contemporary workers had solved the problem of multiple distribution with incandescents, Lowe and others had reduced the water-gas process to a high degree of perfection. Men with oil and patent rights had for some years infested the offices of gas companies with very moderate success. The makers of coal gas had heard the orators of "water," had considered the high cost of the "inventions," compared the uncertain price and limited supply of oil with the steady market of gas coal, had consulted their satisfactory net profits, smiled and continued as before.

Shortly after the general introduction of the electric light, the gas situation changed. The great field of heating by gas was then almost unknown. Gas managers saw the lighting business, almost their sole reliance, rapidly turning to electric stations, and were troubled. Then the hour of the water-gas man was struck. He became the Moses of the hour. Cheaper gas was wanted and the patented apparatus could supply it; greater candle-power was wanted, and oil would give it, so it was claimed. Competition must be met, so gas managers thought, and water gas was extensively introduced. In this movement of the gas interests Massachusetts hung back. The public and the legislators of that State recognized the deadly qualities of water gas, and its distribution was early interdicted by law. During the decade mentioned, the gas interests made repeated appeals to the Legislature for the privilege to freely make and sell water gas. For a series of years these applications were in vain, but at last the arguments of patent owners and oil venders overcame the real or assumed scruples of legislators, and a bill removing the restrictions on the distribution and sale of water gas was approved April 30, 1890. Since that date the fears as to water gas have proved to be only too well founded, for the deadly stuff has ended the lives of more than 300 victims in Boston alone.

However, the industrial side of the question is all that can be considered here. The great argument for water gas was that it would serve to check the rapid advance of electric lighting, by means of lower prices and higher candle-powers than had prevailed with coal gas. It is the purpose here to test this argument by the hard facts of experience. This may be done in two ways. First, by comparing the growth of the gas and the electric lighting industries since the removal of the restrictions on water gas. Second, by noting the ratio which water gas has held to the total volume sold. Boston has been the proving ground for much the greatest water-gas experiment in Massachusetts, and figures from this field are thus selected in the present case. No better measure of the growth of the gas industry could be desired than the volumes of gas annually sold to consumers, as this avoids any uncertainty due to changes in price. Figures are accordingly given for the cubic feet of gas sold to consumers during each year from 1890 to 1901, in all parts of Boston, except the suburbs of East Boston, Jamaica Plain and West Roxbury. In these suburbs no water gas has ever been sold. Unfortunately, it is not possible to present figures showing the total sales of electrical energy in the Boston territory during this series of years. There are no census figures, unfortunately, to refer to, so far back. The growth of electrical supply may be approximately measured, however, by the number of tons of coal burned each year in electric stations. The number of tons of coal burned yearly by the three largest electrical supply systems in Boston, which generate most of the energy sold in the city, are, therefore, given. It should be borne in mind, however, that while the cubic feet of gas sold form an accurate measure of the expansion of that industry, the same cannot be said of the weight of coal burned in electrical supply, because the delivered energy has increased faster in amount than the fuel consumed. Consequently, the showing for the electrical industry is less favorable than are the real facts. Delivered energy has increased in amount faster than the coal consumed because electric stations have been much improved in efficiency since 1890. For the fiscal year ending on June 30, 1890, the relative amount of water gas was small, because no gas might then be distributed that contained more than 10 per cent. of carbonic oxide. Notwithstanding the removal of restrictions on water gas in 1890, the total volume of combined coal and water gas sold did not go up immediately, but on the contrary declined a little. During each of the four following years the figures for total sales of all gas ranged below those of 1890, and in 1894 the volume sold was 93 per cent. of that in the earlier year. This falling off in the total sales of combined coal and water gas took place in spite of the fact that water gas, of which only 193,000,000 cu. ft. were sold in 1890, reached a volume of 1,378,000,000 ft. in 1894. Meantime the coal consumed by the electric stations increased from 24,589 tons in 1890 to 50,374 tons in 1894, touching 53,675 tons in the "expansion" year that ended June 30, 1893. In other words, during four years after the legal restriction on water gas was removed, the total sales of both coal and water gas declined a little, but the coal consumption at electric stations more than doubled. For the fiscal year of 1894 water gas rose to 90 per cent. of the total sales in the Boston territory, without increasing the combined output of coal and water gas, or checking the rapid extension of electrical supply. In the following year the gas situation changed. What water gas had not done and could not do, boost the total gas output, was accomplished by other means. Under date of June 19, 1894, one of the large Boston gas companies issued a circular offering a $17 gas range free, connected in position, to any of its customers, this range to become the absolute property of the customer after the exclusive use during one year of the company's gas. This move naturally evoked competitive measures on the part of the other gas companies. Though these gifts of gas stoves were prompted by material competition, they did what could have been done in no other way, aside from a large reduction in prices; that is, they caused a rapid increase in the volume of gas sold. Under the stimulus of free stoves the volume of annual gas sales rose from 1,524,000,000 ft. in 1894 to 2,271,000,000 ft. for 1896. There need be little uncertainty as to the use to which this increased volume of gas was put. In 1894 the number of gas stoves in use at Boston was so small that the gas commissioners did not record it in their report. On June 30, 1895, the number of these stoves had reached 23,881, and by the like date of 1896 the number was 49,610. In view of these figures for stoves and of the previous uniformity of gas sales, it is clear that the increased volumes of gas during these two years were mainly devoted to heating. While the gas companies were enjoying the expensive luxury of business obtained by the payment of "chromo" premiums, the electric lighting industry was slowly expanding on a more conservative basis. From the middle of 1894 to the middle of 1896, the period of two fiscal years, the total volume of gas sold increased 49 per cent., and the weight of coal burned by electric stations 17 per cent. By the end of June, 1896, the gas interests had grown tired of giving away stoves and the practice was soon thereafter discontinued. When free stoves could no longer be had, the expansion of gas sales came to an abrupt end. During the three years following 1896 the total volume of annual sales of gas established in that year was hardly maintained. Compared with the 2,271,000,000 ft. of 1896, the volume for 1899 was 2,269,000,000 ft. Water gas formed much the greater part of the total output from 1894 to 1899, but it was powerless to expand the volume of gas sold, as shown by the stationary condition of the industry during the three later years of this period. If water gas could not bring about larger total sales of gas or even hold what had been gained by the gifts of stoves, neither could it check the onward swing of electric lighting. From 1896 to 1899 the consumption of coal at electric stations increased 28,162 tons, or 50 per cent. of the weight burned in the earlier year, while the gas industry was vainly trying to maintain its record. This year of 1899 is a good point from which to look back over the record of the gas and electric industries since 1890.

Volumes of gas sold in the Boston territory and the volumes of water gas:

Year.	Cubic feet, total.	Cubic feet water gas.	Percentage of total. coal.	water.
1890	1,627,336,951	193,352,779	88	12
1891	1,507,756,807	561,891,635	63	37
1892	1,527,604,172	902,625,048	51	59
1893	1,594,531,897	1,170,658,199	27	73
1894	1,524,864,297	1,378,106,905	10	90
1895	1,869,378,991	1,815,289,524	3	97
1896	2,271,327,822	2,077,223,942	9	91
1897	2,288,566,862	2,080,759,737	9	91
1898	2,258,640,970	2,184,781,672	3	97
1899	2,269,367,070	2,194,963,361	4	96
1900	2,397,835,462	1,804,888,902	25	75
1901	2,553,229,570	955,723,749	63	37
1902	2,700,792,329	1,200,163,970	56	44

During the nine years, gas has had two of rapid increase and seven years of nearly stationary output. Compared with 1890 the fiscal year of 1899 shows an increase of total gas sales, amounting to 39 per cent. In the same nine years electric lighting has had two years of nearly stationary output and seven years of rapid increase. While the volume of gas sold gained 39 per cent., the weight of coal burned at electric stations went up 242 per cent. The rate of increase of annual fuel consumption in the electric plants has thus been 6.2 times as great as that in the volume of gas yearly sold. Meantime the aggregation of patent gas processes and oil accomplished a purpose, but did not check the electric industry.

Tons of coal burned by the Edison, Boston and Suburban electric lighting systems of Boston:

Year.	Tons.	Year.	Tons.
1890	24,589	1897	60,566
1891	31,645	1898	70,578
1892	47,683	1899	83,872
1893	53,675	1900	80,489
1894	50,374	1901	80,058
1895	51,162	1902	65,131
1896	55,710		

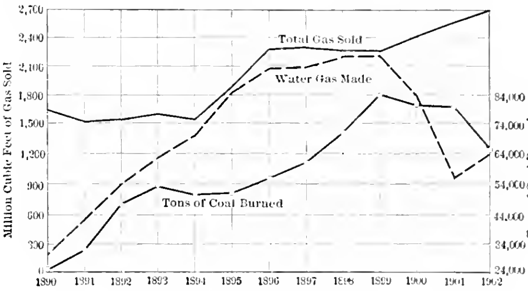
Water gas, starting with only 12 per cent. of the total volume of gas sold in 1890, increased rapidly to 90 per cent. of the entire volume in 1894. From the fiscal year last named to that of 1899 inclusive the percentage of the water gas made to the total product sold was never below 90, and in two instances stood at 97.

During these five years water gas substantially displaced coal gas in the local field, but not in one of them did its brilliant illuminating power or alleged low cost of manufacture check the expansion of electrical supply. In only two years out of the five was the total volume of gas sales materially raised, and then the increase was due to gifts of gas stoves. These stoves appear to have raised the annual consumption of gas about 750,000,000 ft., which would leave the volume of gas yearly burned for illumination just about stationary from 1890 to 1899, inclusive. Now a stationary consumption of gas for illumination in the face of an increasing population means an actual decline in the use of gas per capita for that purpose. It is highly probable that this is just the situation which the Boston gas interests have to face. For the decade from 1890 to 1900 the increase of population at Boston was 25 per cent. If the fifty odd thousand gas stoves now used in the city are doing much baking, it seems hardly probable that illumination by gas has kept pace with the population.

Consideration of the years 1900 and 1901 has been reserved until this point, because they present several new and interesting conditions in the gas and electric field. For the first time during the eleven years under consideration, gas sales show a substantial gain without the aid of an artificial stimulus, like gifts of gas stoves. This gain in the volume of gas sold for 1901 was 12 per cent. over the volume for 1899. Strange to tell, however, while the total volume of gas was going up, that of water gas, the cheap, brilliant illuminator, went rapidly down. From 96 per cent. of the total volume of gas sold in 1899, water gas fell to only 37 per cent. of the like volume for 1901.

This is not the time to explain or guess at the inside working of gas deals. A consideration of the exact causes that lowered the percentage of water gas from 1899 to 1901 would be as much out of place here as would the causes that raised it from 12 in 1890 to 97 in 1895. Of prime interest from the electrical point of view is the fact that a gas, which was introduced with much noise about what it would do to electric lighting, has failed to maintain the advantages formerly gained by coal gas, and failed even in the struggle with coal gas to hold the Boston field against the latter. It is the irony of fate that water gas, from which so much was expected, should be in a rapid decline during the only two years since its general introduction when the volume of gas used for illumination shows any material gain. A glance at the figures and curve for coal burned at electric stations from 1899 to 1901 seems primarily to indicate that at last the long and rapid expansion of electrical supply has been checked. The tons of coal burned, which stood at 83,872 in 1899, were down to 80,058 in 1901. Instead, however, of a failing prosperity, electric lighting in Boston has enjoyed the double advantage of increasing business with a declining fuel consumption during the two years in question. The higher economy of fuel has been effected by marked changes in electric generating stations. To a large extent the generating equipment of 1899 was that of 1890. Comparatively small, simple engines, working non-condensing, and many belted dynamos, did a large part of the work of electrical supply in the Boston field during the year ending June 30, 1899. Under these conditions a rather large consumption of coal per unit of energy output was inevitable.

During the fiscal year of 1899 the Boston Electric and the Edison systems had in use 81 engines and 215 dynamos. In the year of 1901 nearly all the work of these systems was done with less than



GAS AND COAL CURVES.

24 engines and 85 dynamos. These engines all worked condensing and both the engines and dynamos had average capacities much beyond those of the earlier year. A reduction in the amount of coal burned by the electric stations during 1901 from the weight consumed in 1899 was thus due to increased economy of operation, and not to failing business. Further and conclusive proof of this fact is found in the figures for incomes from sales of electrical energy in the Boston field during the years under consideration. For the fiscal year of 1899, the combined incomes of the Boston Electric, Edison and Suburban Companies from the sale of electric light and power amounted to $1,900,052.82, and the corresponding sum for 1901 was $2,348,207.14, an increase of 23 per cent. over the former year. This increase is almost double that of 12 per cent. recorded for the rise in the volume of gas sales between the same years. While electrical supply was making this latest gain, completing two decades of unparalleled expansion, there was a shrinkage in sales amounting to 57 per cent. in the volume of the gas that failed.

Russian Telephones.

The Russian and German post-offices have arranged to construct a telephone line between Berlin and St. Petersburg, via Edtykuhneu, on the German frontier, and Wilna, in Russia. The construction will begin in 1904.

Long Swiss Road.

Two engineers of Zurich, Switzerland, Messrs. Grote and Westermann, have recently applied for a concession to build an electric railroad in the Bernina Pass, Canton of Graubünden. This new road will run from St. Moritz to Pontresina, thence over the Bernina Pass via Poschiavinatal, to Tirano, where it will connect with the Veltlin electric road, a branch of the Adriatic Railroad Company. The new road will have a length of about 40 miles.

Telephone Spring Jack Decision.

We are indebted to Mr. F. F. Sapp, of the North Electric Company, Cleveland, for the following clear digest of the recent decision in regard to telephonic jack springs noted last week:

Some two years ago the Western Electric Company entered suit against the North Electric Company, at Cleveland, upon the following patents, covering the construction of spring jack switches: 357,538, Charles E. Scribner, February 8, 1887; 488,033, Scribner & Warner, December 13, 1892, and 552,729, Charles E. Scribner, January 17, 1896. The second patent, that to Scribner & Warner, is one which has long been considered to be one of controlling importance in the telephone field, and the well-known features of the type of spring jack manufactured by the North Company were confidently asserted by the Western Electric Company to be plainly an infringement on the sweeping claims of this patent. These claims have frequently been sought to be evaded or avoided by manufacturers of telephone apparatus, but relating as they do to the employment of long and short springs for controlling the two limbs of a telephone circuit, the evasions, to say the least, have been doubtful.

The other patents relate more particularly to features of construction of the strip of jacks. The first, the "early Scribner patent," discloses a spring jack switch fully assembled, and insertible in, and removable as a unit from, the comb-like strip or frame of rubber, which is bored and slotted to receive within its body, a number of such jacks. The parts of this jack, corresponding exactly to similar parts of still earlier spring jacks, are punched from sheet metal, assembled in parallel planes, and secured together with rubber insulators, by means of a transverse screw and pin, to form a complete jack, which is fastened at its rear by "a single screw" passing through a laterally extending ear or lug into the edge of the rubber frame or strip.

By reason of this arrangement, the patent states: "On removing the screw of any jack it is evident that the jack may be removed, and all parts of its parts thus made accessible for adjustment or repairs."

Obviously, the thin metal punchings described are lacking in the strength necessary to withstand ordinary service, but the patent further says: "Being, however, connected together and supported by the rubber frame, as before described, they will be sufficiently rigid to be durable and effective for the purposes for which they were designed."

Four claims, 1, 2, 3 and 5, were declared upon. The first, second and last, relating to these individual jacks in combination with the slotted rubber mounting frame or comb-like support formed to contain said jacks, and the third claiming the completely assembled jack, but separate and apart from the frame. The principal reference relied upon by the defendants was the well-known type of spring jack shown in the expired patent to Richard V. Freeman, No. 309,218, dated December 16, 1884, under which suit was brought some years ago by the Bell interests at Detroit. A number of other references were offered in evidence relating to certain features of the Scribner construction. In the Scribner & Warner patent another type of spring jack is shown, designed for specialized use in a single portion or section of a multiple switchboard. It has two springs of different lengths, adapted to engage separate corresponding contact parts upon a switching plug, provided for insertion in the jack. The two springs have normal inner contacts, from which they are separated by inserting the plug.

In this patent in suit, a tubular test piece is permanently connected with the longer of the two line springs in the jack, as stated in the patent: "In order to make the contact between the sleeve of the loop plug and one of the springs more certain and to adapt the plug for use in multiple switchboard systems" while the end or tip-contact, of the plug is of smaller diameter than the sleeve, as in prior patents, in order that the longer spring "may be so adjusted as not to form contact with said tip," although no advantage or function is mentioned as being attained thereby.

The first and third claims were relied upon by complainant; the first setting forth, not in a spring jack but very broadly, in "a circuit-changing device," an admittedly old combination of elements, as is shown by the file wrapper, including two springs, their normal contact pieces, and the tube or guide, in combination with this old two-contact plug, having its tip smaller than the sleeve; a feature previously adopted to prevent its making contact with and closing circuit through the frame of the early individual jacks. In the third claim is set forth the combination with two springs, here specified as being of different lengths, of the "guide in front of said springs," and a plug having two terminals, one upon the tip, whose size is not specified, and the other upon the sleeve. Both claims are somewhat amplified by the recital of functions accomplished by the elements thereof, but without in any way confining the alleged invention to spring jacks, or any other specific form of circuit-changing device. Two patents of Charles E. Scribner, 383,013 and 427,123, were employed to show the strong probability that no joint inventorship actually existed with respect to the features broadly claimed in this patent in suit, while that of Trayer & Kugler, No. 377,788, of February 14, 1888, clearly discloses the use of long and short springs in an earlier spring jack switch.

The last patent in suit, Scribner, 552,729, also describes a specialized form of spring jack adapted for use in a single portion of the multiple switchboard, and was designed in part to accomplish much the same purpose as was the device of the last patent in suit considered.

The patentee says that he has provided a spring jack "whose switch contacts shall be accessible for testing to determine the insulation and continuity of the circuit wires." This he accomplishes by the use of a rubber mounting plate of distinctive character, recessed to contain the inserted spring jacks; each of the receiving grooves provided therein being forwardly expanded or enlarged to afford ample space for the extremities of the four springs of the inserted jack. Rubber insulating tongues or washers, as in the early Scribner patent, electrically separate the several springs; all of said parts being laterally bored to receive two insulating pins for securing the jack parts together, prior to individually mounting the jacks in the grooved plate, by means of two side screws inserted rearwardly in the rubber frame, and bearing upon the rear of the said jack parts. The patent further states that each jack "essentially comprises," among other parts, two short thimbles, *d* and *e*, forming "the usual 'local' contact pieces which are connected with the annunciator for the purpose of restoring it and for testing purposes."

Claims 2 and 4, declared upon, relate to the grooved strip or plate of insulating material, with jacks comprising, respectively, the line springs, and the line and inner contact springs, separated by interposed tongues of insulation, inserted on edge in the recesses or grooves; both of said claims omitting, however, all reference to either of the two thimbles; one being necessary in a jack for multiple switchboards for testing purposes.

Claim 8 specifies simply a partial spring jack, comprising the duplicated line and contact springs, together with their interposed rubbed tongues, and the connecting transverse insulating pin extending through each of the parts.

Against this patent, among others, was cited the one to Scribner & Patterson, No. 489,571, showing substantially the frame or strip for mounting springs flatwise therein, while patent No. 458,258, granted August 25, 1901, to the well-known French inventor, L. A. Berthon, sets forth a strip of spring jack switches having characteristics very closely approaching those set forth in the claims declared upon.

At the hearing of this suit at Cleveland in November last, the complainant found it expedient to dismiss as to claims 1 and 2 of the early Scribner patent, and claim 8 of the last patent in suit. Judge Francis J. Wing, having had the case under advisement since then, filed an opinion December 21 dismissing the bill of complaint at the cost of the Western Electric Company, thus scoring a victory for the North Electric Company and for the independent interests upon three separate patents previously considered of prime importance.

New York Traction.

The managers of the Metropolitan, or Interurban Street Railway interests of New York City, have recently intimated their desire to compete for the building of further subway traction systems on the Island of Manhattan. President Belmont, of the Interborough Underground and Manhattan Elevated, intimates that a transfer arrangement covering all this vast travel might be preferable. The Metropolitan will change from horse to electricity some 40 miles of track during 1904.

Methods of Signaling and Operating in Telephone Exchanges.—III.

By KEMPSTER B. MILLER AND CHARLES S. WINSTON.

WHEN a subscriber calls for a private branch exchange, the connection is established in the reverse order from that just described, the main office operator ringing down the drop at the private branch end of the trunk by the same operation that she would use in calling a regular subscriber. The private branch operator then listens in on the circuit, and obtains from the calling subscriber the particular branch exchange connection he desires.

The matter of supervising a private branch exchange connection has been the subject of much discussion and final disagreement.

There can be no disagreement as to the proper supervisory signal of the regular main exchange subscriber, for when connected with a subscriber in a private branch exchange he will always have the supervisory signal of the plug connected with his line under his control during a connection, no matter what system is used. The only point to be decided then in regard to the supervisory arrangements is, how shall the branch exchange subscriber clear out or re-signal the office?

On considering this point we find that three different methods have their advocates, and each has been put into commercial use to a considerable extent.

The first of these methods is to place in the control of the private branch subscriber during a connection, the regular cord circuit supervisory signal at the main office only, so that this lamp will light at the main office when the subscriber hangs up his receiver, in exactly the same manner as if he were on a regular subscriber's line entering the main office direct. Upon both subscribers hanging up their receivers the main office operator would pull down the connection, and in doing so the removal of the plug from the private branch exchange trunk jack would light the disconnect lamp at the private branch exchange, after which the private branch operator would pull down the connection.

From the standpoint of clean operating at the main board, this scheme is perhaps best of all. It is found, however, that this arrangement is not desirable from the standpoint of the private branch subscriber, and also has its disadvantages in regard to the city subscribers who desire connection with the private branch exchange. As illustrative of this point, it may be said that a main office subscriber will often call up a certain member of a business firm through its private branch exchange; on stating his business this person, so called, will at once recognize that the business may be best transacted in another department, whereupon, instead of being able to signal the branch exchange operator direct by moving his hook up and down, he is obliged to tell the person who desires to transact the business to call up another line in the private branch exchange. This necessitates the calling party beginning all over again at the main office, and securing the connection perhaps over another trunk line.

This fault is eliminated in the second of the three methods in which the private branch exchange subscriber has within his control during a connection, a lamp at the private branch board only, the action of his hook causing no effect whatever at the main office. Under this condition a disconnection is effected when both subscribers hang up, by the private branch exchange operator first pulling down the trunk connection in response to the lighting of the lamp under control of the private branch subscriber, thus lighting the supervisory lamp at the main office. The main office subscriber having also hung up, the subscriber's operator at the main office sees both lamps lighted and pulls down the connection. It will be seen that the operation at the main office is thus rendered in nowise special, the subscriber's operator receiving both supervisory signals in exactly the same manner as if two local lines had been connected, the only difference being that instead of both supervisory lamps being operated directly by the movement of the subscriber's hooks, one of them is operated by the action of the private branch exchange operator in pulling down the connection.

With this arrangement a private branch exchange subscriber who has been called and who desires to have the calling party put in connection with another person in the private branch exchange, has only to move his hook up and down to signal his own private branch operator, whereupon she will complete the connection with the calling subscriber and whatever other private branch exchange line is designated. Another advantage of this second method of supervisory signaling is that if the branch exchange subscriber desires to signal for another connection, after the close of a conversation, he can at once secure the attention of the private branch operator and have her attend to it for him, hanging up his own receiver until she secures the party wanted. This system has the disadvantage of requiring a somewhat more complex cord and trunk circuit at the private branch exchange.

In the third method, used to a large extent by both Bell and Independent companies, the private branch subscriber has within his control the supervisory signal at *both* the private branch exchange and the main office, thus when he hangs up his receiver both lamps light, thus sending in a disconnet signal directly to the main office and to the private branch office simultaneously. Under this arrangement some confusion is liable to occur by both operators coming in on a circuit at the same time in response, for instance, to the private branch subscriber's action of moving his hook up and down. In doing so he usually desires the attention of the private branch operator, rather than of the main office operator, and the main office operator may notice this at once and cut her telephone out of the circuit. If the private branch subscriber desires to have the party with whom he is connected, connected with another line in the private branch exchange the main office operator is not likely to pull down the connection in response to the movement of his hook, because the main office subscriber will not have hung up his receiver, as he will be waiting for the new connection.

This method of having the signals at both the main office and the private branch office under the control of the private branch subscriber, has an advantage in point of simplicity and first cost, as the circuits are very simple, and it has a further advantage in that it tends to clear the main office cord circuits quicker after a connection than in the second method described.

All things considered, from an operating standpoint only, it is probable that the second method, where the private branch subscriber controls a supervisory lamp at the branch exchange only, is best. It is not, however, quite so simple as the third method, and therefore the item of first cost and maintenance enters as an offset.

There appears to be no definite standard for the operation of private branch exchange systems established by the various Bell companies, as, apparently, the different operating companies have their own ideas which the manufacturing company follows. There seems, however, to be a tendency among these companies to adopt the method of operation in which the private branch subscriber's supervisory signal goes to the private branch operator alone, the disconnect signal at the main office being given when the private branch operator pulls down the connection. However, the system which now appears to be standard for the Chicago Telephone Company, employs the third method, having the supervisory signals of the private branch subscriber go simultaneously to the main office and to the private branch operator.

In this latter system the arrangement of the signals is somewhat ununusual and is of interest. The private branch exchange trunks terminate as usual in the main switchboard in the same manner as any subscriber's line. At the private branch exchange they terminate in a jack and lamp, the lamp being under the control of a locking relay, which is operated by the calling generator from the main exchange, but which, when operated, locks by means of an additional coil, energized by current from the local common battery at the private branch exchange. In operation, therefore, the main exchange calls the private branch exchange by ringing on the trunk line in just the same manner as if the call was being sent on the regular city line.

Instead of having supervisory lamps associated with each plug of a pair, there are no separate supervisory lamps on the private branch exchange board, but in lieu thereof the calling lamp of each line is made to serve, it being, after a connection is made, put under the control of the subscriber on its line. Thus the lamp serving as a line lamp when a subscriber takes his receiver from its hook, goes out when the operator plugs in. However, the act of plugging in by the operator changes the circuit of the lamp so that it will again light when the subscriber hangs up, to again be put out when the operator pulls down the connection. This double use of the line lamps is perfectly permissible in small boards because the lamp is always adjacent to a plug when the connection is made. Its lighting, therefore, leaves no doubt in the mind of the operator as to which plug and cord requires her attention. This would not, however, be possible in a multiple board.

The method of supplying current for talking and signaling purposes to private branch switchboards has been the subject of much thought, and the usual practice is now, unless the private branch board is very close to the central office, to install a separate storage battery at the private branch exchange, and to charge this over the trunk lines when not in use.

In the system of the Chicago Telephone Company, just described, this battery is normally fed to the cord circuits on the private branch board through retardation coils in the usual manner, so as to serve when two private branch subscribers are talking together. If, however, a private branch subscriber is connected through a trunk to the central office he draws his talking current directly from the main office battery over the trunk lines, a locking key being provided for each circuit by which the operator may cut off the battery from the pair of cords when so used.

In some of the private branch exchange systems installed by the Kellogg Company the private branch operator is provided with the regular pairs of cords and plugs for making all connections, each cord and plug being provided with a supervisory signal the same as in larger common battery exchanges. The trunk line terminates on a private branch board in a jack and an ordinary ring-down drop, this drop being manually restored by the operator in response to a ring from the central office; otherwise the operation of the system is the same as that of the Chicago Telephone Company, except that the act of cutting off the battery from any cord circuit is accomplished automatically rather than manually. This battery is normally connected with each pair of cords and plugs; but as soon as the operator inserts the plug in the trunk jack a relay is operated which cuts off the battery from the cord connected with the trunk jack, thus allowing the signal connected with that cord to be operated by battery from the main office.

In most of the Kellogg systems, notably those of the Home Telephone Company, of Los Angeles, the third method of conveying the clearing-out signals is used, where both the main office and the private branch exchange operator receive the private branch exchange subscriber's clearing out signal simultaneously. In these systems the trunk line ends in a plug and a drop, the operator connecting a trunk to any private branch line by inserting the plug of the trunk into the jack of the private branch line.

The trunk line is in this case provided at the private branch end with a supervisory signal in the form of a lamp, this lamp, together with the supervisory lamp of the cord used at the central office in connecting with the other end of the trunk line being under the control of the private branch subscriber during a connection. We believe that this plan of terminating the private branch end of the trunk lines in plugs is also largely used by the various Bell companies. It, of course, necessitates a change of cords by the private branch operator when a trunk connection is to be made, as she usually answers a local call by inserting one of the plugs of a pair of local cords into the line jack.

As between the ring-down drop, and the lamp as means for receiving trunk calls at the private branch board, it is difficult to see why the latter is desirable. As a rule, the private branch exchange operator has very little to do, and on account of the reasons already mentioned, simplicity in her apparatus is very desirable. For this reason it appears that if an ordinary ring-down drop offers any advantages in simplicity over the locking relay and lamp, or if the same is true of the termination of a trunk in a plug rather than in a jack, it is advantageous to have the private branch operator give a somewhat less artistic signal or make a few extra movements for the sake of this simplicity.

Sometimes in private branch exchange work it becomes desirable to use party lines, and to afford means for the different parties on a line to call each other without calling the branch office, or to call the branch office without calling the other stations on the line. This is often desirable in large institutions extending over considerable territory. It affords the advantages of a private line between various departments in combination with that of city service. In giving such service as this in connection with the modern exchange system, it is customary, while supplying all current for talking purposes from a common battery, to resort to magneto calling between the stations of a line. Thus each station is provided with the usual common battery talking and call-receiving apparatus, and with a magneto generator adapted to be bridged across the line when operated. In order to prevent the line signal at the private branch exchange being operated by the current from the magneto generator, a differential line relay is used, having one winding in each limb of the line. Any current sent over the metallic circuit of a line will therefore not operate this signal, and thus any subscriber on the line is enabled to call any other, the same as on any bridging-bell party line. In order to enable any subscriber to call the central office, a push-button key is provided which grounds the live side of the line, thus causing the operation of the line relay and lighting the line signal.

It is sometimes necessary in very large institutions to provide two private branch exchange switchboards, as where the same firm has different buildings in different parts of the city. Where this is the case it is better to provide trunk lines directly extending between the two private branch exchange offices, in order to prevent the necessity of having calls for connection between subscribers in the two different exchanges being handled through one or more of the city offices. Where the two private branch exchanges are very large it is probably better to use one-way trunks, the same as between two offices in a city exchange. Where, however, the exchanges are comparatively small and the number of trunk lines few, it is the best practice to provide two-way trunks in order that either trunk may be used in either direction. Where such is the case the usual arrangement is to terminate each trunk line at each private branch board in a jack and a lamp. When the operator at one end plugs into the jack of the trunk line two lamps, one at each end, light simultaneously. Both lamps are extinguished when the operator at the other end plugs in in answer to the call. The first operator is therefore made aware of the response or non-response of the operator at the other end of the line. As soon as either operator pulls down the connection at one end both lamps light and both are extinguished when the other operator pulls down the connection. It usually requires quite a complicated circuit to produce this result without using more than two wires in the trunk line; but as trunk lines in large cities are expensive the complication is warranted when the lines are of considerable length.

A type of private branch exchange service new, so far as the writers are concerned, has recently come into use to a limited extent on the Pacific coast, or, more specifically, in both Bell and Independent exchanges at Los Angeles. The system used by the Home Telephone Company at Los Angeles (Independent) is, it is thought, the more complete of the two, and is worthy of description. It combines some of the features of the ordinary private branch exchange with those of the ordinary intercommunicating telephone system, wherein each subscriber is enabled to make his own connection without the intervention of an operator. A line is therefore provided for each private branch subscriber, terminating at each station in a jack. Each subscriber's telephone set consists of the ordinary common battery talking apparatus terminating in a plug, and also in a push-button for calling and a battery bell for receiving calls.

Each subscriber may, therefore, call any other subscriber in the private branch exchange by simply plugging into the jack belonging to the line of that subscriber, and pressing the button. So far the system is the same as the ordinary intercommunicating or house system. In addition to the local subscriber's line, however, each trunk line to the main exchange is extended through all of the stations in the private branch exchange terminating at each station, as before, in a jack. Each of these trunk lines also terminates in two jacks and a magneto bell on an attendant's desk, the attendant being provided with a telephone set similar to that of the subscriber, and also with a separate closed circuit plug for the purpose of holding the line. If any subscriber desires a connection with the city exchange he has only to insert the plug of his telephone set into the jack of one of the trunk lines. If the line is busy he learns the fact by hearing the conversation in progress, and in such case is expected to withdraw his plug. If, however, the line is not busy the operator at the main office responds in the usual manner, as the line lamp belonging to the trunk line is lighted. The subscriber calling then gives his order directly to the main office operator, and the connection is completed in the usual manner. An incoming call from the main exchange rings the bell on the trunk line at the attendant's desk. The attendant plugs into one of the jacks of that line and answers, inquiring what party is wanted. Learning this, she usually plugs into the other jack of the trunk line with the holding plug, which keeps the circuit of the trunk line closed, and therefore prevents the clearing out signal being sent. She then inserts her telephone plug into the jack of the line of the subscriber wanted and calls him. When he responds she tells him that he is wanted on trunk line No. 1 or No. 2, as the case may be, and he inserts his plug into the jack of that trunk line, after which the operator may withdraw the holding plug. When the private branch subscriber hangs up, the disconnect signal is sent directly to the main office in the same manner as if he were on an individual line.

Such a system is employed only where the services of a special operator are not required at all times. The stations are generally all within reach of the sound of the bell on the attendant's desk, and therefore, if the attendant is not present any subscriber may respond when he hears the bell by plugging in directly into one of the trunk line jacks. If there are more than one of these he can usually tell which one by the sound of the bell.

Such a system is not universally adaptable, and is only applicable where a few stations are required and where a comparatively high-grade class of subscribers is to be found. Such a system would be rendered practically unusable if two of the subscribers, finding themselves on the same line at the same time, were not willing to give way to each other promptly. It will be interesting to watch the development of this class of service in the future, as, from its popularity when installed, there appears to be some reason for its existence.

Wireless Telegraph Theory.

In a paper read before the Nantes Congress of the Association Francaise pour l'Avancement des Sciences in 1898, Prof. Blondel presented a simple method of representing the disturbance of the ether produced by a vertical antennæ. This consisted of a polarized hemispherical wave, the electric lines of force being circular meridians and the magnetic lines of force circles of revolution. In a paper read before the congress of the same association held at Nantes in 1902, Prof. Blondel returned to the subject, prefacing the paper with a statement that various English and American authors had given different representations of waves, figuring them as elliptical tores of constant height sliding on the surface of the earth and increasing only in diameter (Fig. 1).

Prof. Blondel considers this view to be erroneous and resulting

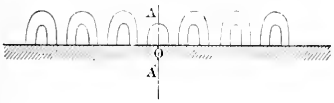


FIG. 1.

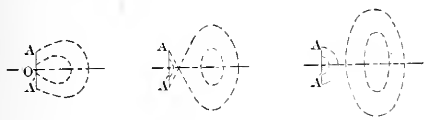
from an incomplete interpretation of the theoretical results of Hertz, on which they state they base their conclusions. It is easy to show, on the contrary, that the representation of the field in the vicinity of the antennæ which accords with the work of Hertz, is in perfect harmony with the production of long-distance spherical waves.

Prof. Blondel reasserts that the antennæ-earth system is equivalent to a Hertz oscillator of double length ($A\,A'$, Fig. 1), attained by adding to the antennæ, $O\,A$, a symmetrical portion, $O\,A'$, formed of its electrostatic image with respect to the surface of the earth, which latter plays the rôle of a conducting surface (the hypothesis of a perfect conductivity of the earth is evidently only approximate, but sufficient for the elementary theory). The field in the vicinity of this rectilinear oscillator ($A\,A'$, Fig. 2), is analogous to that



FIGS. 2, 3 AND 4.

which Hertz investigated around a small rectilinear electrical oscillation.

This field is formed by a series of loops which close on themselves and then are detached and proceed perpendicularly to the wire of the oscillator and constantly expanding. The substitution of a finite rectilinear exciter for the small oscillation does not modify the phenomenon qualitatively, still giving us loops describing circles of revolution representing the field of force.

The manner in which the loops become detached can be deduced from the figures of Hertz as Prof. Fleming has pointed out, and may be explained with reference to the diagrams of Figs. 2, 3 and 4. The positive and negative charges, or electrons—to use the latest terminology—proceed in an inverse sense toward the opposite extremities of the exciter, but remain bound by lines of force, as in the case of any mass of electricity decomposed in its electrons. During the first part of this movement the electric lines of force form loops of increasing dimensions, as is shown for a given case in Fig. 1, then the propagation is subject to a reflection at these extremities and the loops close little by little (Fig. 2); next, owing to the inertia of the electrons, these pass beyond the position of equilibrium, O, and the lines cross, as shown in Fig. 3; finally after crossing, they separate into distinct loops, as is shown in Figs. 3 and 4, and the detached loops continue their course as free waves. The presence of the earth permits only the continuation of the upper halves of the loops.

But it should not be understood that the loops proceed by a simple movement of translation while retaining their form (Fig. 1), for the lines of force tend to spread out in all directions; they increase in height in the same time that they propagated along the earth, at which they touch practically normally as on any conducting surface. At the same time they curve toward the vertical axis of the antennæ, as in the case of experiments with Hertzian fields at small distances. The propagation of lines of electrical force should then, I believe, be represented in the form drawn in abridgement in Fig. 5. I say "in abridgement" because the spherical form is not, in

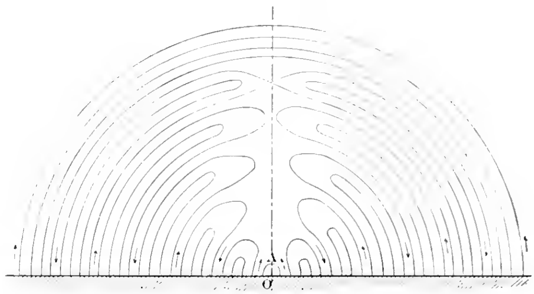


FIG. 5.

fact, attained as rapidly as that figure indicates, which is a simple diagram having no pretensions to mathematical exactitude.

This figure shows that little by little the loops in spreading out end by joining on the axis of figure and finally become perfectly spherical. From that moment the propagation will be purely transversal and with the velocity of light. Before attaining the limiting distance beyond which the waves are spherical, the field follows laws much more complex; the speed is not that of light, the lines of force oscillate as Hertz has shown, and the phenomena are complicated and difficult to analyze; for ordinary purposes, however,

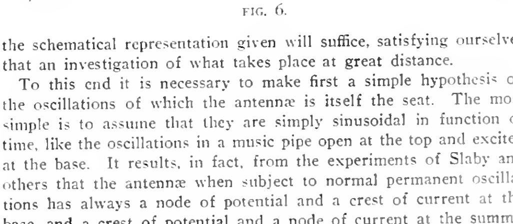

FIG. 6.

the schematical representation given will suffice, satisfying ourselves that an investigation of what takes place at great distance.

To this end it is necessary to make first a simple hypothesis on the oscillations of which the antennæ is itself the seat. The most simple is to assume that they are simply sinusoidal in function of time, like the oscillations in a music pipe open at the top and excited at the base. It results, in fact, from the experiments of Slaby and others that the antennæ when subject to normal permanent oscillations has always a node of potential and a crest of current at the base, and a crest of potential and a node of current at the summit (Fig. 7). If we neglect, lacking other recourse, the perturbations at the extremity where the wave reflections are produced (and experiments seem to give this right, for in charging the form at the extremity and adding there small spheres or plaques or various kinds of points, no change in the length of wave is appreciable), and if we neglect also the variations of the capacity and of the linear inductance along the antennæ, the equation of the current can be written in the following elementary form:

$$I = I_0 \cos \frac{\pi z}{2H} \sin \pi \frac{Vt}{2H}$$

in which I is the current at the point z and at the time, t; I_0, the amplitude of I; z, the height of the point considered, H that of the

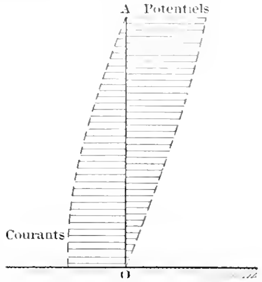

FIG. 7.

antennæ and V the velocity of light. This being assumed, an approximate calculation can easily be made showing the manner in which the energy is distributed on a spherical wave at great distances.

The paper of Prof. Blondel develops in detail mathematical expressions based upon the above assumptions. The result shows that the forces in the field vary as a function of the angle Θ_0, the angle between the direction of an element of current and a vector which is perpendicular to the electrical and magnetic forces, as is shown in the expression.

$$\frac{\cos\left(\frac{\pi}{2} \cos \Theta_0\right)}{\sin \Theta_0} \qquad (1)$$

On the other hand, the energy varies perpendicularly to the radial vector of Poynting, or according to the expression,

$$\frac{\cos^2\left(\frac{\pi}{2} \cos \Theta_0\right)}{I_0^2 \sin^2 \Theta_0} \qquad (2)$$

It is easy to see that the reception depends upon the energy received by the antennæ; this is evident for thermic or other analogous receptors which integrate the energy received in unity of time, but is equally true for receptors of the coherer type, which are sensitive to electric shock received upon the arrival of each train of waves. In fact, one ordinarily defines the condition of coherence by the voltage necessary to produce it; but it is evident that in order to obtain the soldering of metallic particles there is also necessary a certain minimum quantity of electricity; that is, it is the product of the current by the potential that determines coherence. Now, two antenna of equal height can give rise to an equal e.m.f., but that which has the largest surface gives rise to the largest quantity of electricity and produces consequently the better effect at the receiver, as may be readily determined. It is, therefore, the energy received by the antennæ in the form of electric and magnetic lines of force which affects the reception. The sensitiveness may be considered as proportional to the radius vector, the expression for which, $r = r_0 - z \cos \Theta_0$, forms part of the calculation above referred to.

It is thus seen that the effect of waves decreases inversely as the square of the distance and not inversely as to the distance according to the theory of Taylor, which has recently been criticised by Prof. Fessenden. On the other hand, if we consider in function of the angle Φ, the curve corresponding to the factor (2), we obtain relative values represented by the vectors of Fig. 6. The following table indicates these relative values in function of the radius directed according to the horizontal taken as unity:

$\Theta_0 =$	0	.019	.0176	.185	.312	.482	.667	.836	.956	1.0
	0	10	20	30	40	50	60	70	80	90

We see that the energy decreases rapidly as we arise above the horizon; the preceding theory, therefore, accounts for phenomena observed by various experimenters. In France, in particular, Capt. Ferrié has received signals in a balloon at heights of some hundreds of meters above the earth and distinctly observed the rapid decrease of reception with height. In addition, it is quite evident that the curve of distribution preserves the same form at all distances; but the further one is away the less can he be from the earth to receive perceptible signals, since the energy decreases in absolute value.

This theory, which assumes the earth to be a perfect conductor, applies directly to transmission over the surface of the sea; it is, however, only approximate in the case of propagation over earth only slightly conductive, which then is to be considered a semi-dielectric. When the waves propagate themselves to great distances the curvature of the earth intervenes; but it does not interfere with the propagation, as we know from the propagation of waves along conducting bodies; the waves turn in in such a manner as to follow the surface, as has been shown by the experiments of Sarrasin, de la Rive, Blondlot and others.

To resume, the simple application of known properties of Hertzian waves are sufficient to explain in a satisfactory manner all the phenomena observed without it being necessary to attribute to waves new or mysterious properties. In this note I have confined myself to rendering clearer the interpretation of the phenomena, and to explain how, notwithstanding the very complex conditions and the difficulty of analyzing what passes in the vicinity of the antennæ, the propagation at great distances resolves itself simply to that of hemispherical waves, as I showed in 1898.

Hemispherical waves are polarized waves; it is for this reason that they do not propagate energy in an equal manner in all angular directions, and present a maximum effect toward the horizon and no effect toward the zenith.

Transportation in Brooklyn.

The December Grand Jury of Kings County, Brooklyn, N. Y., has filed a presentment on the street railway system, which it considers wholly inadequate. A local body of electrical commissioners with power to secure remedies is demanded. The presentment says:

The third-rail question, one which affects our people to the greatest degree in view of the many accidents which it causes, thanks to the careless methods of the companies as far as relates to the repair of their rolling stock and electric appliances, is, we are assured, receiving the careful attention of the heads of the corporation. It is possible that in time, when a method will be found cheap enough to be attractive which will lessen the perils caused by that means of electric traction, the management will adopt it, if it ever becomes convinced that it will prove cheaper than the eventual payment of damage suits resulting from accidents. But here, again, there is no one empowered to make them adopt the safety device, be it ever so perfect.

It is readily seen that as there are no laws to govern the case, no ordinances to be enforced, no authority whose province it is to enforce them, cars will continue to be overcrowded, the service will continue to be irregular, people will continue to be subjected to freezing temperatures and drafty vehicles; the lack of headlights on trains, the electric current of the third rail, defective insulation due to slovenly repairs in the machine shops, will continue to kill and maim people, and there is no redress but the verdict of "accidental homicide" on the part of the coroner, or at best a verdict for damages on a case where the negligence of the corporation is too flagrant.

In order to afford some remedy, the few laws and ordinances which have been enacted must be complied with, and freed from any ambiguity which makes their execution impossible. Others af a stringent nature, though perfectly fair and reasonable, providing severe penalties for infraction, must be passed by the competent authorities, Legislature, or council, under the clause of the public welfare and safety, and their enforcement should be intrusted to a local body of electric railroad commissioners.

To this end, we, the December Grand Jury of the Borough of Brooklyn, call upon the proper authorities, municipal assemblies or State Legislature, or both combined, to give us without undue delay, a proper code of laws specifically enacted to govern the local transportation companies. These laws, while protecting fully the franchise rights of the transportation companies, and enacted with due fairness to all, must clearly define the rights of the citizens, and regulate the mutual relations of both in the process of transportation.

The Effect of "Wireless" on Improvement in Wire Telegraphy.

By JOSEPH B. BAKER.

IN the summer of 1902 there was a controversy in the columns of THE ELECTRICAL WORLD AND ENGINEER between Messrs. Delany and Barclay, that constituted the latest chapter in the old dispute between the supporters of conservative methods of handling telegraph traffic and the believers in the application of more modern and speedier methods of transmission to the benefit of the public service. In an article in these columns in the issue of July 19, 1902, the present writer drew attention, first to the apathy of the telegraph companies, expressed by their indifference to the progress that had been made in rapid telegraphy systems; and, secondly, to the unquestionable fact of the existence of practical systems for enormously increasing the transmission capacity of existing lines—systems that are far beyond the experimental stage and quite ready to be put into use. In this communication it is sought to show how the present aspect of these two related facts, truer than ever as they are to-day on their own merits, is affected by the work that has been done in the last few years in the art of telegraphing without wires.

Marconi and the earliest workers in space telegraphy were soon obliged to realize that the matter of signalling through space meant dependence upon a new set of *natural* phenomena. They were able to signal only by the application of electric energy in a form natural and proper to the sending circuit including an elevated conductor, whereby a distant similarly arranged receiving elevated conductor and circuit upon which could impinge a minute fraction of the original energy borne by the ether as a non-conducting medium of propagation, was made to reproduce the signals. Only by such application of electrical energy, namely, the generation of Hertzian waves by oscillating currents natural and proper to the circuits of the terminal apparatus, could signalling without a connecting line be effected over more than moderate distances. This is illustrated by the facts that the electrostatic induction method of Edison, being dependent upon what may be called forced ether strains due to current flow between capacity area and ground at unnaturally low periodicity, was not effective beyond very moderate distances; while the free discharge at the spark gap of Marconi's vertical wire, whereby the wire, situated favorably for disturbing the ether surrounding it, had its electric charge set into natural vibration, has been developed in a comparatively few years to the point of transatlantic signalling under favorable conditions.

The early observed fact that a receiving antenna and circuit similar to such apparatus at the sending end constituted a pair of stations capable of working through distances very great compared to the distances that could be covered by dissimilarly arranged stations, was the first step toward modern syntonic space telegraphy. Experimenters in "wireless" had to attack the problem of tuning, not at first, indeed, or even as yet for the sake of rapid telegraphy by the new method, but for the sake of being able to signal at all. In a word, the development of the new art left no escape from the fact, held in abeyance as long as wire telegraphs were the only ones in use, that the signalling energy should be of a form proper to the apparatus and medium of propagation used. The desirable in wire telegraphy, the scientific method of signalling, hitherto neglected and despised by telegraph companies satisfied with crude and primitive methods, became for "wireless," wherein the connecting "line" was absent, an absolute essential of commercial operation. The wire telegraph works, to the satisfaction of vested interests controlling it and of an unenlightened public, by an electrical use of the wire as crude (in comparison with what might be gotten out of the line by adapting the constants of the terminal apparatus and the frequency of the signalling electromotive forces to the constants of the line) as communication by hammering on the end of a steel rail to be heard at the other end compared with conversation by telephone.

"Wireless" work and achievements now place existing systems of rapid telegraphy, the work of some of the best brains in this country, in a new light: and show more clearly than before the advantages—hitherto absolutely ignored and wasted—inherent in the having of a conductor, connecting the sending and receiving stations, able to give direction to the wave-borne signals. Such a connecting wire is easily able, also, to become a main-traveled road for many sets of signals, each set transmissible at a speed so far in excess of that attained by the present handwritten "Morse," as to be in a wholly different class, by the simple plan of using the transmission line as it should be used; that is, the plan of applying the signalling energy in a form natural and proper to the electrical constants of the line and its terminal apparatus. These considerations, in the eyes of workers in wireless telegraphy, suggest improvements of incalculable value in wire telegraphy. The having of a conducting line to carry the signalling impulses with but little loss (comparatively speaking) directly to the receiving station, reduces the realization of these improvements to a simple matter of providing multiple-tuned sending apparatus and corresponding receiving apparatus, in the use of which the capabilities of a single wire become at once so exalted over its present use by "Morse" as to make this single wire more than the equivalent of a heavy pole line with each wire quadruplexed.

All this raises the question: Can the telegraph companies continue to resist progress in rapid telegraphy? With a public gradually becoming enlightened upon the whole broad subject of electrical waves, and welcoming the rapidly spreading use of machine telephone operation with its revolutionizing effect on that important traffic; with the existence of practical rapid telegraph systems already many years old and comprising the work of men of the most unquestioned eminence in applied electricity as well as in the narrower field of telegraphy; and finally, with the existing lines coming to be recognized by an enlightened public as being entirely capable of use in the carrying of an enormously greater business with correspondingly lower rates than at present, will it be much longer possible for conservatism and indifference to public need to maintain outworn and primitive conditions?

Telephone Transmitters.—III.

By ARTHUR V. ABBOTT, C. E.

THE perfection of the solid back marked an important era in the development of the transmitter. It was so successful that since its completion the American Bell Telephone Company have discontinued the use of other forms and have gradually replaced those of earlier construction with the solid back, until now it is rare to find any other in use. Since the original design of Mr. White there has been little change in the solid back, excepting in minor matters of detail, and when the patent situation became such as to invite the more courageous of independent telephonists to undertake the manufacture of transmitters, the first effort was to copy the solid back in an attempt to produce a model which should equal it; so the majority of transmitters upon the market are more or less close imitations thereof. In most respects the attempt has been made to keep each transmitter as near as possible to the original type without patent infringement, but some builders have shown considerable ingenuity in changing the details of construction and some have even gone so far as to entirely depart from the fundamental principles. Transmitters, therefore, can be divided into three classes:

1st. The solid backs, or those which are, to all intents and purposes, copies of the White.

2nd. The elastic cell transmitter, in which there is no secondary flexible diaphragm, but the receptacle containing the carbon is made of elastic material (such as a ring of felt) and the diaphragm is pressed directly against this ring. Such instruments are described more forcibly than elegantly by the term of *"Cornplaster"* transmitters.

3rd. Double diaphragm transmitters.

Considering the first class, the transmitter manufactured by the Kellogg Switchboard & Supply Company is a prominent example. A full-size section through the Kellogg transmitter is shown in Fig. 17. In Fig. 18 the rear cap is removed. In Fig. 19 the instrument is entirely dissected and in Fig. 20 a front view of the diaphragm is shown. The section of Fig. 17 shows the instrument to consist of a solid face plate, *a*, which is almost exactly similar to that of the White instrument. A hard rubber mouthpiece, *a*, is threaded into a hole into this plate. There is a perforated partition just in front of the diaphragm, the object of which is to prevent injury to the transmitter from the too curious, who often like to investigate a telephone by poking it with a lead pencil. Across the base plate and bolted thereto a substantial brass bridge, *h*, is placed. As shown in Figs. 18 and 19, this bridge differs from that used in the White instrument in being perfectly straight. The diaphragm, *b*, Fig. 17, is made of aluminum essentially the same size and thickness as that used in the White transmitter, but possesses a distinct feature in that the receptacle to hold the front electrode and the granular carbon is formed in the diaphragm by pressing a cup-shaped depression in the center.

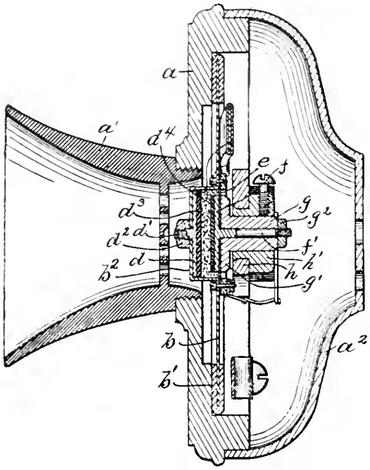

FIG. 17.—SECTION OF KELLOGG TRANSMITTER, FULL SIZE.

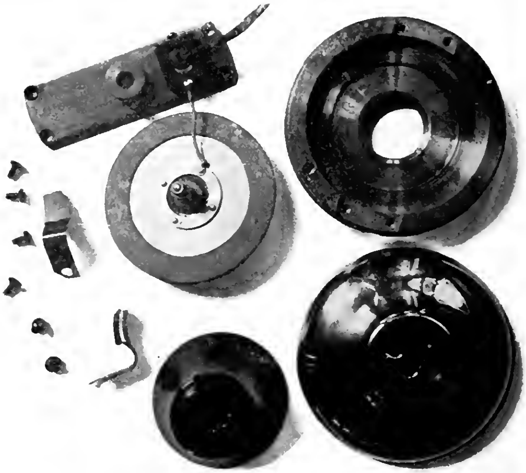

FIG. 19.—KELLOGG TRANSMITTER DISSECTED.

This construction is shown clearly in Figs. 19 and 20. The front electrode, d^3, Fig. 17, is a thin, flat piece of carbon highly polished and brazed to a brass disc, *d*, furnished with a short, small stem, d^1. This is inserted in a hole drilled in the center of the bottom of the cup pressed in the diaphragm and by means of the nut, d^2, the electrode is clamped in its place. The rear electrode, d^4, in Fig. 17, is formed of a similarly shaped disc of carbon about ⅛ in. less in diameter than the front electrode. It is also brazed to a brass disc provided with a shank, f^1, placed in the center of a circular mica disc, *e*. On the outside of the mica disc a brass nut, *g*, is slipped over the shank, f^1, and clamped by means of the nut, g^2. The necessary amount of granular carbon is placed in the cup, the rear electrode inserted; the mica washer then covers the entire opening of the cup. A thin aluminum ring is then placed over the mica washer and riveted. This hermetically seals the electrodes and enclosed carbon. The shank of the brass disc, *g*, is then inserted in the bridge and clamped in its proper place by a set-screw. By this design the rear electrode is clamped firmly against the bridge, but the entire cup containing the front electrode and carbon vibrates with every motion of the diaphragm. So the first essential difference between the White transmitter and that of the Kellogg Company is that in the White instrument the carbon receptacle is fixed and in the Kellogg instrument it is movable. It is claimed that this motion of the carbon receptacle is efficacious in preventing packing, because the carbon is constantly in motion. This has not conclusively been proven, and it is doubtful if the motion of the diaphragm is sufficient to be of material aid in stirring up the carbon granules. There is much evidence to show that prevention of packing is more a matter of mechanical design in obtaining the relative, proper sizes of electrodes, diameter of carbon receptacle, thickness of layer of carbon and proper sizing of the individual granules, than to any method of stirring up the transmitter in order to release the granules from a clamped position. The circuit of the Kellogg transmitter is very

FIG. 18.—KELLOGG TRANSMITTER, CASE OPENED.

FIG. 20.—KELLOGG TRANSMITTER DIAPHRAGM.

FIG. 21.—GROUP OF TRANSMITTERS.

similar to that of the White, inasmuch as the diaphragm is connected to an insulating binding post placed upon the bridge, to which one of the line terminals is attached. This affords electrical connection

FIG. 22.—AMERICAN TRANSMITTER WITH COVER REMOVED.

FIG. 23.—AMERICAN TRANSMITTER DISSECTED.

with the rear electrode. The front electrode is insulated by the mica washer and the rubber ring which encloses the diaphragm. Therefore, by connecting the other line terminal with the transmitter case, circuit is obtained through the carbon granules.

Not only in the general principles of construction, but also in exterior conformation the various transmitter manufacturers, have closely adhered to the design of the first solid back. This is evidenced by Fig. 21, showing a group of six well-known transmitters, of which the following is a list:

A. Swedish-American transmitter.
B. Wilhelm "
C. Intensifying "
D. Manhattan "
E. Century "
F. Ericcson "
G. Williams "

These instruments and a few other models will be described somewhat more in detail.

The American Transmitter.—The transmitter manufactured by the American Electric Company is shown in Fig. 22, with the cover removed, and in Fig. 23 entirely dissected. It consists of a heavy face plate carrying an aluminum diaphragm, cushioned by a rubber strap. Across the face plate a brass bridge is screwed, as shown in Fig. 22, the capsule being included between the diaphragm and the under side of the bridge. The cover of the transmitter is a hemispheric case of spun brass fastened by two specially-formed nuts, which prevent its removal excepting with the aid of a particular tool which will fit the nuts in question.' In Fig. 23 the bridge is removed and turned upside down. The capsule containing the granular carbon consists of a thin spun brass cup, over the face of which a mica diaphragm is placed, and the entire capsule closed by spinning a brass washer over the mica and the edge of the cup.

Lighting at the St. Louis Fair.

The contract for lighting the World's Fair, which has been awarded to the General Electric Company, is the largest exposition illumination contract ever let. It provides for supplying the Exposition with 300,000 incandescent lamps at 13.6 cents each, or a flat outlay of $40,800. This contract for lamps followed the completion of sketch plans for lighting the exhibit places, grounds and architectural features belonging to the Exposition proper, but is exclusive of state, national and private concession buildings. The detail plans are now being drawn.

To give an idea of the distribution of these lamps, it is stated that 12,000 are to be placed on the Palace of Education alone. The classical outline of that building eliminates brilliant color effects, but furnishes a splendid setting for night effects produced by electric lights.

It has been decided to place on each of the monumental standards which dot the main avenue of the Exposition, on the border of the waterways, 24 incandescent lamps. Each of these standards has four cast-iron pendants, on each of which there will be six lights. The "Pike," or Midway, will be furnished with sufficient lights to render it brilliantly illuminated. Each of the standards along the central avenues will hold 24 lamps, so distributed that 12 will hang on each arm of the supporting post.

The lamps contracted for will be used exclusively for exterior lighting. The interior of the exhibit buildings, which will be closed at sunset, will be lighted with arc lamps, the chief object of this lighting being for patrol purposes.

The western half of the north facade of the Educational building has been equipped with lamps. This is merely a test section, installed for the purpose of trying the effect of lights between the columns. Results of the tests have proved satisfactory in every way

Cleaning Third Rail.

Cleaning the third rail appears to have been done successfully by the Grand Rapids, Grand Haven & Muskegon Railway Company, which has an exposed rail and is operated through an open country. A solution of chloride of calcium poured on the third rail has instantaneously removed a covering of ice or sleet, and, moreover, protected the rail so that it has not covered again with ice for at least three hours. These tests have also shown, it is said, that the solution will not injure either the steel rail or the copper bonding. Three cars on that line have been equipped with reservoirs, located in the motorman's vestibule, from which tubes extend to a point directly over the third rail. In this reservoir the solution is placed. A stop-cock regulates the flow of the fluid.

Mr. George Westinghouse.

One of the customs of the Westinghouse Electric & Manufacturing Company is to have an annual reunion at its works of all the district managers, and a social feature of these occasions is a dinner where the visiting delegation meet in familiar converse with the principal members of the technical and other staffs of the works. At such a meeting several weeks ago Mr. F. H. Taylor, second vice-president, took occasion to make some remarks having for a subject Mr. George Westinghouse, in which he presented a character sketch intended to meet the interest of those present who did not know Mr. Westinghouse intimately, or who might know only of his activities in the field of their own work. The remarks naturally were not intended for publication, but realizing the interest they would have to our readers as an intimate portrait presented thus informally by a close business associate, we requested a copy for reproduction in our columns. Having finally overcome the reluctance to publicity for remarks delivered under the circumstances, we are enabled to give below Vice-President Taylor's address, which we believe will be read with much interest.

GEORGE WESTINGHOUSE:

Mechanic;
Inventor;
Tireless organizer;
Financier;
Friend of labor;
Founder of enduring industries.

What all the world knows needs only to be mentioned to you who are his associates in business.

The revolution in railroading wrought by the developed air brake;

The appreciation of an opportunity that recognized the importance of the discovery of natural gas in the Pittsburg district and controlled its development;

The resourcefulness and ingenuity which won the great victory at the World's Fair in Chicago;

The courage that triumphed over the difficulties of a financial crisis;

The power that has grown so fast as to keep ahead of the unparalleled increase in the industries started but a few years ago, and now appalling in their size and extent;

The executive ability that has been the controlling factor in the Westinghouse interests, which have become so numerous that no one here in an hour's time could write out a list of them and have it complete.

These interests have grown so large and the number of responsible officers has become so great that Mr. Westinghouse is not as intimately known to you as I should desire, and as I am sure he himself would desire if it were possible.

Some of the peculiarities which have aided him to acquire his present position may be illustrated. For example, it is unusual for an inventive genius to be so perfectly open-minded to the inventions of others. I sometimes think he is as happy over the discoveries of other minds as though they were his own. (He has found a means for the development of new inventions all his life.) Great intellects have worked for him, been encouraged by him and been protected by him. I name at random: Shallenberger, Tesla, Scott, Parsons, Nernst, Ruud, Cooper Hewitt, Thomas, Davis, Bremer, Lamme, Wurts, Lange. His mind is constantly reaching out into the future, and after one has been much with him it becomes practically impossible to live altogether in the present, because there is brought to view at every turn possibilities of new things yet undeveloped which are to serve future generations at a time when the world has advanced far beyond its present stage. The imagination is constantly stimulated and interest kept alive by the new principle that is struggling on towards definite shape.

There is always present the evidence of good will toward every one; a quick appreciation of the good points of other people. In the course of his life he has been forsaken by friends who lacked courage to follow him, and in its main crisis he was greatly hampered by heart-breaking incidents of this kind. Yet no one has ever heard him say an unkind word of any who differed with him. His foresight is phenomenal. The industries in this country have grown up even faster than seemed wise to a great many who were associated with him. They did not see the value of what he was doing as clearly as he saw it, and time alone has justified the thoroughness with which plans have been laid, buildings designed and executed. Energy and expense have not been spared upon any of the works. They have been developed in such a way that they can be extended forever.

No sooner had provision been made for this country than many of his closest friends were startled by a move upon Europe and the markets of the world. Some men have charged this move to a mere ambition to plant his name in Europe. They wondered that he should tax his resources and take upon himself the tremendous strain which has finally resulted in the great organizations and plants in England, France, Russia and Germany.

The associates who questioned his wisdom did not have his foresight and did not see that these things were necessary for the protection of the initial developments in the United States. I give no importance to my own judgment in this matter, but Mr. Westinghouse knew that the foundations here would have been insecure had not the foreign field been entered during his period of maximum activity. We shall live to see all the effort justified, and the Westinghouse interests the world over fitting together and helping one another.

After all, what is the ultimate aim of it? Men work for wealth, for social position, for the esteem of professional associates, for the applause of the world. These things may be nominated ambition and of that all men must plead guilty.

In the case of Mr. Westinghouse the aim is not immediate wealth. He has done his work too thoroughly to have that as his goal. From my closer observation of him I should determine that he meant to leave a monument upon the earth that shall be strong enough to stand alone without consolidation with other interests, and that shall bear his name for a hundred years. Napoleon's words to his brother when he was made ruler of Spain were: "My one word of advice to you—be master," and I anticipate that the Westinghouse interests will be master of anything they associate with during the next century. By that time the appreciation of what Mr. Westinghouse has done for the world will be clearer and more just than it is to-day.

Great men cannot be compared one with another. They are moulded by circumstances and no two are alike any more than two great trees are alike, yet no man is truly great who lacks certain essential qualities: First, he must at all times be just, and in the case before us this quality has prevailed. A great nature shows itself by being kind and considerate. The underlying sweetness of his spirit is illustrated by the watchword that he uses among all his interests—a constant repetition of a plea for harmonious action. Other virtues are shown by the cleanness of his life. You who have, at times, worked for other kinds of men must know the power that comes to those who work for a clean man, and one who demands soundness of thought and expression. He is never satisfied with surface appearances, but seems to look right through to the heart. His mind is so quick that he sees the essential point in a complicated situation even before the story can be fully told to him. Once determined upon his course, he is not to be laughed out of it, frightened out of it, nor bought off.

The boundless hospitality of his home has been often mentioned, but when one has had the opportunity repeatedly of seeing him there, he is impressed with the uniform cheerfulness of the man and of his sustained interest in every detail of household life. I saw somewhere a letter from a wife written upon the birthday of her middle-aged husband. In the letter this sentence appeared: "To me, you will always be my young lover." This one sentence defines Mr. Westinghouse in his home.

To one associated with him in business, it has often seemed that to be loved of the man is an aim worthy of a life of devotion to his interests.

I have referred to the fact that all men have their ambitions. Every one here is anxious for a broader field, and I am sure will attain to it. Yet every one of us has arrived at an age when we can make a fairly good estimate of our probable attainments. This is our annual dinner and it is a good time to take an account of stock. My judgment is that there is in our organization an opportunity for every man to be satisfied. For myself, first of all, I want a conscience void of offense. Next, I want to leave some record in the world for my family. I should like to be remembered as one who has accomplished something. I, too, want to leave a monument. My ambition is not for popularity nor for fortune. I am satisfied if I leave my children the inheritance that their father had been able to catch something of the spirit of a great leader, and that he had been somehow useful in perfecting that leader's work and in developing his plans. For me it shall be enough that I served under George Westinghouse; that I was counted one of his efficient lieutenants.

CURRENT NEWS AND NOTES.

A NEW ELECTRICAL DICTIONARY.—An electrical dictionary is now being prepared in France, which will be published in three volumes, each of 700 to 800 pages. Prof. J. Blondin, of the Sorbonne and editor of our French contemporary, *Eclairage Electrique,* will be the author.

A CORRECTION.—In the article by Prof. R. A. Fessenden, appearing in our issue of November 14th, the statement on the sixth line below the cut showing a mast, should be "12 or 13 interfering stations," instead of "135 interfering stations."

LONG DISTANCE RECORD FOR ELECTRIC AUTOMOBILE.—The world's record for long distance run by an electric automobile, on one charge, has been established, according to a Washington dispatch, by Mr. F. B. Whitney, clerk of the House Committee on Naval Affairs. On December 23rd, Mr. Whitney made a run of 121 miles in 10 hours and 32 minutes—an average speed of 12 miles an hour.

STORAGE BATTERY SEPARATOR.—The only electrochemical patent granted on December 22nd refers to a separator for storage batteries, invented by Mr. Hugh Rodman. About a year ago Mr. Rodman patented the use of a wooden diaphragm between each pair of plates of a storage battery, the diaphragm having acid wells. The object of this separator was to provide free circulation of the acid from the top to the bottom through vertical grooves or wells cut on the sides of a wooden sheet. While any kind of wood may be used, yet porous or fibrous wood is preferable. In that patent it was stated that diaphragms of wood possess unique and remarkable properties which adapt it for the purpose, and the properties mentioned there were efficiency, durability and capacity. These separators have evidently found extended use in practice, and it has thereby been discovered that where the wood comes in contact with the peroxide of lead of the positive plate, the nascent oxygen causes deleterious rotting of the wood. In his new patent Mr. Rodman therefore provides means for keeping the wood from coming in contact with the lead peroxide. These means may, for instance, consist in a sheet of rubber, or the grid of the positive plate may be provided with projections which touch the wooden diaphragm, while the active material does not come in contact with the wood. The inventor states that the term "wooden" is intended to include such materials as paper and other cellulose fibre products.

ROWLAND'S EXPERIMENT.—Several years ago M. Cremieu, as the result of experiments, questioned the accuracy of Prof. Rowland's epochal experimental proof of Maxwell's great hypothesis on the identity of electromagnetic and luminous undulatory transmission. This proof consisted in demonstrating experimentally that if a static discharge were to move with the velocity of light, it would have the effect of a current. At the suggestion of Prof. Rowland, Mr. Harold Pender made experiments at Johns Hopkins University with the method of Cremieu, but got results which corroborated instead of contradicted Rowland's proof. With the hope of reconciling these contradictory results, M. Henri Poincaré undertook, in the fall of 1902, to bring about a collaboration between M. Cremieu with Pender, and at the suggestion of Lord Kelvin, Paris was chosen as the most favorable place for the proposed joint experiments. The Carnegie Institution furnished the funds necessary to defray the personal expenses of Mr. Pender, the expenses of actual experimenting being met by the Institute de France. The result of the work was communicated in the form of a joint paper to the Société Francaise de Physique, a translation of which appears in the current issue of the *Physical Review.* The work of the two experimenters, as described in this paper, is a beautiful example of scientific investigation, the result of which was to confirm absolutely the accuracy of Prof. Rowland's proof. The joint experiments disclosed a fundamental inaccuracy involved in the experimental apparatus of M. Cremieu due to the kind of dielectric employed, which exercised a screening or neutralizing effect due to the very considerable charges absorbed by the particular dielectric employed in an essential part of the experimental apparatus.

LETTERS TO THE EDITORS.

A Singing Vacuum Tube.

To the Editors of Electrical World and Engineer:

SIRS:—It may perhaps prove of interest to your readers to know of a certain phenomenon which the writer observed recently during some experiments with Röntgen-ray and cathode-ray tubes. Possibly some of your readers may have observed similar phenomena, or can suggest explanations other than those which have occurred to me.

Over a week ago, during some experiments, I had the misfortune to perforate the target or anode of one of my Röntgen-ray tubes, and this, in addition to destroying its focusing power, caused the vacuum to lower as the occluded gases in the platinum were driven out. The tube was one of the Queen self-regulating type with the platinum plate of the anode backed by nickel. I laid the tube aside and ordered a duplicate, intending to send the damaged tube to be repaired. A few evenings thereafter (December 24, 1903), I was on the point of packing this latter tube in a large cardboard box filled with excelsior when it occurred to me to try it once more and see if its vacuum had changed and to what extent. After heating the target or anode red hot I laid the tube down upon the closed cardboard box, taking up the new tube and placing it in the holder. Suddenly I heard a low but very clear musical note corresponding to *A* on the musical scale, and which I found came from the damaged tube. On placing my hand on the tube at various parts I could feel it vibrating violently.

I timed the duration of the sound on three separate tests and the musical note lasted respectively 5, 15 and 7½ minutes; in other tests made since it has lasted from 5 to 17½ minutes. Sometimes the tube did not start when first laid down, but invariably tilting and letting it fall back lightly would start it up. Sometimes after it had stopped I could start it again a second or third time without connecting to the coil. The pitch of the sound was always the same save on two occasions, when several persons were talking near the tube; the pitch then varied, but when the room became quiet it resumed its usual pitch. The amplitude of the sound varied, but could usually be heard plainly in an adjoining hall or room from 20 to 30 ft. distant. It should be noted that at the time the tube was singing, the induction coil, which was supplied from the street direct-current lighting circuit of 117 volts, was not running, nor was there anything else near to affect the tube either by an electrical or mechanical vibration; besides, the box and excelsior packing were a perfect cushion. I found that the tube laid on a table or a box sang just as well, and when I placed a long steel needle between my teeth, allowing the point to touch the bulb, the sound immediately ceased, but started up again each time the needle was removed.

By reason of the fact that it was necessary first to warm up the platinum plate by the cathode stream, and as the anode tube was not only perforated but part of its edge expanded away from the nickel backing, one would naturally be led to think the phenomenon was akin to the well-known "Trevelyan Rocker" effect described in most books on Physics, in which the vibrations produced by a heated brass rocker resting on lead give out a clear musical note, although it is impossible to detect the rocker vibrating. Whether the phenomenon is due to the Trevelyan effect or whether instead of a thermal action the musical note was caused by the air between the platinum and nickel plates which was forced through the perforated anode or not I am at present unable to state; but having observed in the *Sun* of December 20 a cablegram from London referring to some experiments in that city, the dispatch stating that a vacuum tube which had been lighted up continued to remain illuminated for ten days after it had been disconnected from the electrical circuit, I have wondered whether it were possible that the conditions of vacuum and perhaps other characteristics of the London vacuum tube and the Röntgen-ray tube were such that after the energy supplied electrically had set the tubes going, they may have been so extremely sensitive that they responded to some etheric vibration which kept them active until they got out of step. In the case of the Röntgen-ray tube, this would soon occur, as the conditions were changed by the cooling of the electrode. Such a stimulation by vibrations in the ether has been suggested by Mme. Curie, Edison, Lord Kelvin and others as one of the theories to account for the phenomena of radioactive substances such as radium, which acted as a transformer. Is it not possible that the light in the vacuum tube and the sound in the Röntgen-ray tube might have been similarly kept going? The writer was particularly interested in the statement cabled from London, as he has frequently called the attention of friends to the curious effects produced upon a vacuum tube presented by Mr. D. McFarland Moore in 1896, and which has ever since been hanging in my laboratory, which tube would flash up at times long after the coil had been stopped and the tube disconnected. It was this sensitiveness to Hertzian waves which led the writer to suggest years ago the use of the vacuum tube as a receiver in connection with wireless telegraphy.

New York. William J. Hammer.

Theories in Wireless Telegraphy.

To the Editors of Electrical World and Engineer:

Sirs:—I have just read with much interest the letter printed in your issue of October 31st from Professor Fessenden, and I was pleased to note the allusion which he was kind enough to make to my publication of 1898, which preceded that of Mr. Taylor. I agree in part with the views of Professor Fessenden, but am not in a position to judge completely since I have not at hand the paper printed in the *Transactions* of the American Institute of Electrical Engineers in 1899, to which he refers. I would only observe that in my opinion there is no need to invent any new kind of wave, as Professor Fessenden appears to do, in order to explain phenomena which the simple theories of Hertz interpret sufficiently well. To render clear my views on this subject, I enclose herewith a short note which I presented last August at Angers before the Association Française pour l'Avancement des Sciences, for the purpose of rectifying the erroneous ideas put forth by Mr. Taylor and others, and to complete the earlier communication, which was not sufficiently full.

As will be seen from this note, it is sufficient to consider the earth as a conducting surface (which is quite true in the case of the sea, and an approximate hypothesis in the case of the earth) along which the lines of force glide, in order to explain very simply the propagation of waves and the hemispherical form they assume. Still more, the very simple formulas that can be established by means of this hypothesis show that the energy received by an antennae is a maximum at the surface of the earth and decreases rapidly at distances therefrom; and that it diminishes inversely as the square of the distance, as in all cases of spherical propagation.

The electromagnetic theory such as I have developed it should not be made to bear the burden of errors resulting from a misapprehension thereof. If Mr. Taylor, who starts with entirely correct ideas, ends by finding a decrease of energy in inverse ratio with the distance, this is merely because he attributes to half waves a constant height and does not permit them to acquire their natural development in space. Experiments made in balloons by several Frenchmen, notably by my friend Capt. Ferrié, of the Engineers, have shown that propagated waves can be detected at very considerable heights. If Professor Fessenden has found this height very limited it is, I believe, simply because the energy decreases rapidly as the distance from the earth increases, as indicated by an energy curv which figures in my note; but one should not confound the lack of sensitiveness of apparatus with the lack of existence of waves.

The researches of Professor Fessenden do not appear to be any more conclusive (at least until I have read his complete publication) as concerns the necessity of adding a metallic conductor of half a wave length beneath the antennae; experiments which we have made in this connection in France have shown that it suffices to have very large metallic surfaces in communication with the earth; indeed, the earth connection may be entirely replaced by a very large metallic capacity. In the experiments, for example, of Capt. Ferrié, he found that a large metallic capacity may be placed at the summit of a tower, using suspended antennae without earth connection, and signals received over a certain distance. The earth serves with respect to the antennae only as a large capacity to store the oscillatory charge constantly passing between the capacity and the antennae in a manner to give rise to sufficient current to affect the indicating circuit.

Nor does it seem to me that sufficient account is taken of the very great sensitiveness which can be obtained with a coherer of gold or pure silver filings, when employed in the manner which I indicated in 1898 (*Comptes Rendus*, April 23, 1900) in combination with a potentiometer. This disposition enables the voltage necessary to produce coherence to be reduced to a very small amount, and permits the voltage of the potentiometer to be put in series with that of the antennae; under these conditions the slightest e. m. f. produced in the antennae suffices for coherence, and one has thus a filings coherer of very considerable sensitiveness, and much greater than ever obtained by Marconi. In France we have experimented with several of the later receiving systems, such as those of Solari and Marconi (hysteresis receivers) without obtaining as great sensitiveness. This does not prevent me from recognizing the interest presented by the employment of the telephone; indeed, I think I was the first to indicate this interest in 1898, when I made it a subject of communication to the Académié des Sciences, May 21, 1900. The arrangement of Prof. Fessenden, which we have not yet been able to test, will indeed be welcome if it involves a sensitiveness as great as he gives us to hope.

Having re-read the article by Mr. A. Frederick Collins on the very interesting discoveries of Professor Fessenden, I beg here to point out that his system of syntonization by groups of waves, described in the patent to which Mr. Collins refers, is anticipated by an application which I have filed for a United States patent along the lines of my English patent of May 3, 1900; and his arrangement for the continuous production of waves recently described appears analogous to one for which I was granted a British patent, July 11, 1902.

These claims, which I make here incidentally, are not intended to detract from the scientific merit of the researches of Professor Fessenden, to which I render homage; and I shall be particularly happy to see published with more detail the curious experiments on the propagation of wave to which Mr. Collins refers briefly. The scientific world will certainly be much interested, and the result will probably be a great progress in our ideas concerning the propagation of waves, regardless as to what will be the final conclusion.

Paris, France. André Blondel.

[A translation of the non-mathematical portion of the Angers paper to which Prof. Blondel refers is printed on page 41. The letter of Prof. Blondel was also accompanied by two reprints from the *Comptes Rendus*, one entitled "On Syntony in Wireless Telegraph" and the other, of which M. G. Dobkevith is joint author, entitled "On the Maximum Sensibility of Coherers Practically Used in Wireless Telegraphy." The first-mentioned refers to a communication deposited in the archives of the Academie des Sciences, August 16, 1898, in which a method of syntonization is proposed consisting in tuning the transmitting and receiving stations, not to the frequency of the oscillations proper of the antennæ, but two artificial frequencies much lower and entirely arbitrary and independent of the antennæ—namely, the frequency of the charges of the antennæ and that of a selective telephone, such as the monotelephone of M. Mercadier. A vacuum tube replaces the usual relay, and in shunt relation thereto is the telephone. In series with the latter is a battery of a strength not sufficient to break down the resistance of the vacuum tube, yet sufficient to produce a current at each passage of an oscillatory current in the tube. The telephone is thus affected at each emission of a signal from the receiving station, and the sound is determined by the number of charges per second given to the sending antenna. At short distances the vacuum tube can be dispensed with and the telephone placed in series with the receiving antenna. An advantage of this method is that the note of the sound in the telephone can be varied by varying the frequency of emission at the sending station, and by employing a telephone tuned to a given sound, selective telegraphy is possible. It suffices to maintain the frequency of the spark coil interrupter constant and equal to that of the receiver. The vacuum tube employed in the experiments was an ordinary Geissler tube having large electrodes almost in contact, but spontaneous decohering devices, such as the carbon coherers of Hughes, Tommasina and others may be used.

The theoretical interest of this method resides in its analogy with the synchronization of a pendulum by periodic shocks, which has been so ably investigated by M. Cornu. Each group of waves of high frequency, rapidly damped, acts *en bloc* as a simple percussion on a telephone diaphragm of slow vibration, which latter is sinusoidal owing to the effect of inertia. Consequently there should be no difficulty in applying at the receiving post the ingenious multiple telegraph arrangement of M. Mercadier. Finally, the principle of mechanical elasticity at the receiving station can be replaced by that of electrical elasticity, as follows: The detector may be mounted in series with the antenna or in shunt with a circuit containing a telephone, an inductance if necessary, and a battery shunted by a condenser. The capacity of the latter is fixed by the frequency of the charges of the sending antenna, so that the circuit is always in resonance, or rather, in pseudo-resonance, with the sending station; the signals will then be selected by any telephone, or to reinforce the effect, by a telephone tuned to the same frequency. The receiving circuits of different frequency can be connected to the terminals of the same tube, but it is preferable to have separate tubes and antennæ.

In this manner a station may communicate simultaneously with any number of other stations, and the different signals only be received by the respective stations tuned thereto.

The second paper relates to a method of increasing the sensitiveness of filings coherers by lowering the critical voltage of decoherence. Critical voltage is defined as the voltage which, applied continuously, prevents the tube from decohering quickly upon shock, its value for each coherer depending on the nature of the metal of the electrodes and of the filings and the degree of oxidation. The conditions to be fulfilled for maximum sensitiveness are that the battery e.m.f. be kept below the critical point; that the e.m.f. produced by the waves be greater than the critical e.m.f.; that to obviate deterioration the current established at the instant of coherence should be below a certain maximum—one milliampere in general; and that to decohere sharply, the current passing through the tube after a shock should be but a small fraction of the preceding current that is, a small e.m.f. applied should produce a large relative variation of resistance. Thus the sensitiveness with a given antenna is increased by lowering as far as possible the critical value by the employment of filings only slightly oxidizable, and placing in circuit a battery of low e.m.f. and a relay of low internal resistance. We can then eliminate the supplementary resistance added in series with the relay to reduce the current, and thus raise to a maximum the relative variation of resistance produced in the cohering and decohering of the tube. The arrangement is still more perfect if instead of a battery a potentiometer across an accumulator cell is employed. The adjustment of the coherer may be made by changing the length of the column of filings by adding filings from a chamber connected to the tube, or vice versa, the effect being to vary the pressure between the various particles of filings.—Eds.]

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Single-Phase Motor.—Corsepius.—An illustrated description of a single-phase motor without commutator, which starts under load. The author refers to the well-known property of the single-phase induction motor that it will not start by itself, but when once started continues to revolve and will give out power, and it makes no difference whether it is started in one or the other direction. The reason of this phenomenon is that the rotation of the motor causes a distinct change in the magnetic conditions; the apparent reluctance of any two portions of the stator winding is not the same, the difference being greatest when the two portions are displaced by one-half pole distance. The author, therefore, divides the stator winding into two equal portions, which are displaced from each other by 90°, in the same way as is usually done in single-phase motors. His motor, however, has two rotors, a main rotor, *a*, and an auxiliary rotor, *b*, shown in Fig. 1, in which *c* is the stator. The main rotor,

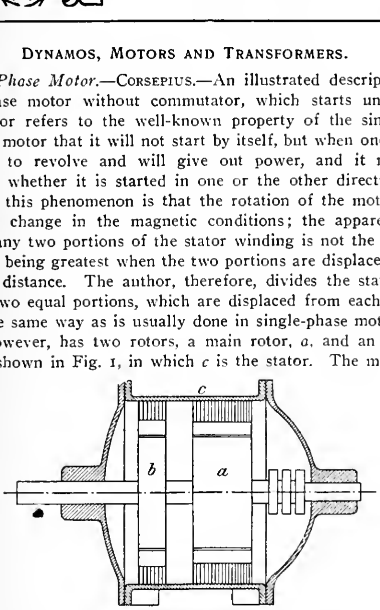

Fig. 1.—Single-Phase Motor.

a, is rigidly mounted on the shaft and its winding is connected with step rings, while the auxiliary rotor, *b*, is loosely placed on the shaft and is provided with a short-circuited winding. When the motor is started, *b* rotates without load and *a* starts then with torque. The auxiliary rotor, *b*, is provided to produce the change in the magnetic conditions, above referred to. To start the rotor, *b*, it is, of course, necessary to apply one of the usual starting devices; for instance, a small resistance. The author gives some data on a small experimental motor of this type, in which the stator part that surrounds the main rotor and the stator part that surrounds the auxiliary rotor are provided with their own individual windings; *e* and *f* in Fig. 2 are the windings surrounding the auxiliary rotor, *g* and *h* those surrounding the main rotor; *e* and *f* are first connected in series to the supply circuit, a small resistance being connected in parallel with *b*. The auxiliary rotor then starts. The small starting resistance is then removed, and the windings, *g* and *h*, are also connected to the supply circuit, whereby the points, *m* and *n* are connected with each other. It will be seen that this gives a network arrangement like the Wheatstone bridge; *g* and *h* are constant; *e* and *f* vary; hence an alternating current passes between *m* and *n*. The currents, *g* and *h*, are different at any moment, while their effective values can be equal. The currents, *g* and *h*, have, therefore, not the same phase. In the tests of the experimental motor the following results were obtained: The motor, when in operation, while giving 2.4, 4.62, 6.83, 7.95, 9.05 hp, took 48.5, 57.0, 68.4, 72.6, 78.4 amp., respectively. When starting under the same loads it took 48.0, 65.6, 86.2, 97.0, 97.0 amp.—*Elek. Zeit.*, December 10.

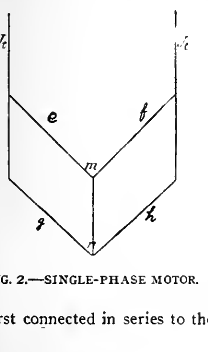

Fig. 2.—Single-Phase Motor.

Starting Torque of Three-Phase Motors with Variable Number of Poles.—Behn-Eschenburg.—A communication on results of tests of two types of three-phase motors, built by the Oerlikon Company, with short-circuited armatures, for four speeds, obtained by a variation of the number of poles. The results for one machine are as follows: This is a 240-volt motor for a normal rating of 7 hp at 250 and 500 revolutions, and about 10 hp at 750 and 1,500 revolutions. The frequency is 50 and the weight 500 kg. The number of poles is 24 or 12 or 8 or 4; the starting current, 58, 60, 150, 116 amp., and the starting torque 25, 10, 18, 7.5 kg, respectively. For normal operation at 50 periods, the torque is 20, 10, 10, 5 kg, the speed 220, 470, 740, 1,470 revolutions, and the current 25, 19, 28, 25 amp.—*Elek. Zeit.*, December 3.

Design of Direct-Current Machines.—Fynn.—A continuation of his illustrated serial in which he says that the choice of winding rests between the form-wound coil and the hand-wound barrel winding, avoiding all soldered joints for any number of wires per slot per layer. Form-wound coils are only of distinct advantage in cases where the conditions of work are extremely severe and may cause a break-down within a few months from the start, however good the insulation and workmanship may be. He claims that a hand-wound armature is much less liable to a break-down than a formed coil. In the same issue he gives in a communication his reasons for advocating the rotation of the commutator opposite to the inclination of the brush.—Lond. *Elec. Rev.*, December 11.

Testing of Generators by Air Calorimetry.—An account of the discussion of Threfall's British institution paper which was recently abstracted in the Digest. Esson thinks that the method involves so many difficulties that it was rather a test of the ability of the experimenter than of the machine. Glazebrook gave some information on the use of the Pitot tube method for determining air pressures. Mordey was much interested in the method of measuring the air currents, since the measurement of the quantity of gas passing through very large pipes for the supply of very large gas engines may soon become very important, and Threfall's results with a Pitot tube show that greater confidence can be placed in this method than appears at first sight. Threfall in his reply claimed that the method was not at all difficult, since anybody who can read a thermometer can apply it. A careless man will get a wrong result whatever method he uses. His method is, however, not a quick test, since one must wait until the temperature equilibrium is fixed, and in the case of his 3,000-kw alternator it took about six hours in order to obtain consistent results. There was some discussion concerning the increase from no load to full load of the iron losses or unascertainable losses. Esson contributed it to losses in the completely laminated poles of the generator. Mordey in other tests had found an enormous increase in these losses in machines with toothed armatures and in machines without laminated fields; that increase of losses was thus probably entirely due to the unequal distribution of the magnetism, to the toughening of the lines and the increase of eddies in the field and to the hysteresis of the armature itself.—Lond. *Elec.*, December 4.

REFERENCE.

German Dynamos.—Guilbert.—The first part of what appears to become a very long and fully-illustrated serial on the construction of dynamos in Germany. The author gives details of the most typical machines exhibited at the Duesseldorf Exposition and discusses alternators. In the present installment a 2,000-kilovolt-amp. alternator of Lahmeyer and a 350-kilovolt-amp. alternator of Schorch are described.—*La Revue Tech.*, November 25.

Lights and Lighting.

Ionic Theory of the Electric Arc.—Stark.—An elaborate investigation applying the ionic theory to the phenomena in the electric arc. To simplify matters, the author starts from the mercury arc, which is longer than the carbon arc, and distinguishes four distinct parts, viz.: the brilliant brush issuing from the white hot depression in the cathode, the dark space, the positive light column and the anode layer. The glow discharge does not necessarily involve the evaporation of the cathode, but the arc light does. It is not essential that the anode should emit vapor. In all gaseous discharges one has to distinguish between electrons, positive atomic ions and molar ions. In the Bunsen flame negative electrons play a very prominent part. In the electric arc, with its higher temperature, they are even more predominant. This is shown by the susceptibility of the arc to magnetic deflection and the readiness with which it follows every variation in the current, owing to the great nobility of the electrons. The impact of the electrons produces positive and negative ions from neutral molecules at the anode and in the positive light. The converse only takes place in the glow discharge, whereas in the arc the negative electrons are produced from the cathode by electrification, and not from the gas by ionization. The ejection of electrons from the interior of the cathode is partly favored by the presence of ultraviolet light, but most of all by the high temperature of the cathode. This high temperature produces in the interior of the metal an electric force driving the electrons toward the anodes. Concerning the old question as to the counter e.m.f. of the arc, the author says that there is a counter e.m.f. in the arc when the anode is very hot and it represents the sum of the internal e.m.f. of the anode and cathode, but is much smaller than the minimum tension. The latter is not due to the counter e.m.f., but to the fact that a minimum of work must be done at the cathode in order to produce the radiation of negative electrons in sufficient density.—From *Ann. der Physik* No. 12; Lond. *Elec.*, December 4.

Photometric Tests of Street Lamps.—An abstract of a report by Bradley on tests of street illumination. The most interesting item seemed to be the comparative costs of candle-power per year, working out at 18.8 cents for the arc lamp and 18.24 cents for the Sugg high-pressure incandescent mantle lamp. It is pointed out, however, that the information is very scanty. While it is said that the tests on the gas lamp were taken at three different angles, these angles themselves are not given. Again, there is nothing to denote how long the mantles have been in use, and considering the variation in the illumination of the incandescent mantle, especially when used as street lamps, it is of importance whether the candle-powers are averages of periodic tests or to know to what conditions they refer. —Lond. *Elec.*, December 4.

Power.

Hydroelectric Plants in Austria.—Some notes on recent developments. The municipal electric station of Innsbruck has recently been opened which gets its power from a hydraulic plant at the River Sill, 11 km. from the city. When completed, there will be six turbines, each of 2,500 hp, and coupled to a 10,000-volt alternator. In the main sub-station near Innsbruck the voltage is reduced to 2,000. The current will be used for lighting, power and traction. In Kruman, in Bohemia, the water power of the Moldan River has been utilized, 6,000 to 7,000 hp being available at the turbines. There are three 2,500-hp turbines, each coupled to a three-phase generator running at 420 r.p.m., and giving 2,500 kilovolt-amp. at a power factor of 0.7, the voltage being 15,000. The current is transmitted to two paper mills in which motors aggregating 2,000 hp are used. The voltage is reduced to 300 volts in the mills by three three-phase transformers aggregating 1,800 kilovolt-amp. The balance of the power is used for lighting and power purposes in towns in the neighborhood.—*Elek. Zeit.*, December 3.

Yorkshire Power Plant.—An illustrated description of the first of the four generating stations of the Yorkshire Electric Power Company. This plant is in course of erection and has a capacity of 6,000 kw. A three-phase system at a frequency of 50 cycles has been selected, the generating voltage being 10,000. There are four generating units, each consisting of the Curtis steam turbine and a 1,500-kw alternator. Each set is arranged with a vertical shaft with the generator above the steam turbine. The generator has six poles and is designed for normal full-load output of 1,500 kw with 100 per cent. power factor at a speed of 1,000 r.p.m. The full-load current is 86.5 amp. and the voltage between terminals 10,000. Three turbine sets, each of 150-kw capacity when running at 2,000 r.p.m., are provided for supplying power for excitation and auxiliary purposes. These turbines are of the Curtis type, arranged with a horizontal shaft. The voltage supply for excitation and power is 220 volts.—Lond. *Elec.*, December 4.

Water Powers in British Columbia.—Jacobs.—An illustrated description of some important hydroelectric plants in British Columbia. It is also pointed out that many important water powers are still unused, the development of which would promise good returns, for instance, in the Rivers Fraser, Columbia, Kootenay and Elk.—*Eng. Mag.*, December.

Niagara Falls.—Buck.—A fully-illustrated description and statistical article on recent developments in Niagara power.—*Cassier's Mag.*, December.

Electric Power for Charging Metallurgical Furnaces.—Kueppers. —A detailed illustrated description of a crane, installed in a metallurgical plant in Russia, for discharging the various furnaces. For moving the crane as a whole and for its traversing movements electric power is used, while for lifting the blocks to be charged into the furnace hydraulic power is applied.—*Elek. Zeit.*, December 3.

Mechanical Stokers.—Gay.—An illustrated paper read before the (British) Society of Engineers in which the author gives a summary of the present situation of mechanical stokers for electric stations.—Lond. *Elec.*, December 11.

Traction.

Conversion of Cable to Electric Traction.—An illustrated description of the methods of conversion from cable to electric traction in St. Louis. The line upon which this change was made does a large business and it was considered necessary to make the change without interfering with the traffic. First a 9-in. girder rail for the electric road was set about 6 in. outside of the cable rail. The paving and the old cable slot rails were then removed. The tops of the cable yokes were broken off and a 6-in. rail for the electric track was mounted on the inside of the cable yoke. The old conduit was then filled in with broken stone. Temporary connections between the old and the new construction were made.—*St. R'y Jour.*, December 5.

Isolated Plants.—MOSES.—An article in which the author suggests organization and records for a moderate-sized isolated electric plant. —*Eng. Mag.*, December.

ELECTRO-PHYSICS AND MAGNETISM.

Permeability of Iron Powder and Iron Wire.—ZENNECK.—An experimental comparison of the change of the magnetic permeability of iron wire and iron powder in alternating fields. In an iron wire the permeability depends largely upon the frequency, and at a frequency of 1,000,000 per second it is about 1/10 to 1/30 of its normal value in a steady field. This is often explained by the supposition that at such high frequency the magnetization can no longer follow the field. This supposition seems, however, questionable, since a similar inability is not shown by iron powder (or at least to a much smaller degree), its permeability being nearly the same at a million periods per second, as it is in a steady field.—From *Ann. der Physik*, No. 12; Lond. *Elec.*, December 4.

ELECTRO-CHEMISTRY AND BATTERIES.

Electrolytic Oxygen and Hydrogen.—An illustrated description of the Schuckert system for the electrolysis of water. A cast-iron trough contains the electrolyte, which is a 20-per-cent. solution of potassium hydrate, and the iron electrodes, which are separated by strips of a good insulating material, extending from the top downward about three-fourths the depth of the cell. Between these separating plates and enclosing the electrodes are suspended iron bells which collect and carry off the developed gases.—*Electrochem. Ind.*, December.

Rôle of Formation Heats of Alloys in Electrolysis.—RICHARDS.—A theoretical note in which the author shows how to apply the numerical values of the formation heats of alloys in calculations of the e.m.f. corresponding to the dissolution of the alloy.—*Electrochem. Ind.*, December.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Recording and Analyzing Wave Forms of Alternating Currents.—HOSPITALIER.—A very long illustrated paper read before the (British) Institution of Electrical Engineers. After some brief introductory remarks on the methods of direct observation by the oscillograph of Blondel and Duddell and the rheograph of Abraham, he discusses at length the indirect stroboscopic methods to which he believes belongs the industrial future, since they have a wider field of application and permit of the direct recording of the phenomenon to be studied upon a strip of paper in the way that is not possible with the direct methods in which recourse is always had to photography. He describes briefly the following forms of stroboscopes, the arcoscope, the stroboscopic transmission dynamometer, the stroboscopic eye-glass and the differential stroboscope. He then describes in detail his ondograph, the object of which is to register directly upon a band of paper, by means of ink, the representative curves of periodically and rapidly varying electrical phenomena, such as e.m.f., current, power, etc. A synchronous single-phase alternating-current motor is actuated directly by the source of electrical energy of which the e.m.f. or current or power is to be recorded. A train of gearing is provided which imparts to a revolving commutator such an angular velocity that when the motor has made a certain number of revolutions, the commutator will have made an equal number, increased or diminished by one. In his commercial instruments a four-pole motor is used and when the motor has made $\frac{n}{2}$ revolutions, corresponding to n periods, the commutator has completed $\frac{n-1}{2}$ revolutions, with a regular and uniform retardation. The commutator consists of a cylindrical block of insulating material, carrying a tube of brass suitably cut to shape, with 3 brushes raised upon it (Fig. 3). The object is to put a condenser, *C*, successively in connection with, first, two points, *u* in the circuit in which the e.m.f. or current is to be recorded; secondly, the measuring apparatus, *E*. During the first operation the condenser, *C*, becomes charged, and is discharged through the measuring instrument, *E*, in the second. For recording the power curve the contact maker is reduced to a simple conducting bar, which, once in each revolution and by means of two brushes, closes the circuit through the fine-wire bobbin of the recording instrument. The condenser, *C*, may be regulated by means of plugs in order to regulate the sensitiveness of the apparatus. For differences of potential and current, the recording measuring instrument, *E*, is a moving coil instrument; for power curves it is an ordinary wattmeter. The main current passes continuously through the fixed primary bobbin, while the movable fine-wire bobbin is placed in the circuit which is periodically connected by the rotating commutator to the difference of potential which determines the second factor of the power. Regulation is effected by introducing resistance into the fine-wire circuit. In the commercial instrument the recording cylinder makes one complete revolution for every three periods recorded. Each of these three curves registered corresponds to 1,000 actual periods and 999 impulses. One complete period takes up a length of 4 in. on the cylinder. The ondograph allows the frequency of an alternating current to be determined with accuracy, since it is only necessary to determine by means of a chronometer the time occupied by the recording cylinder in making one complete revolution. As this time corresponds to 3,000 periods, this number divided by the duration of one complete revolution in seconds gives the frequency in periods per second. The recording apparatus comprises two distinct parts—the directing arm and the recording pen. The former is a rigid lever attached to the measuring apparatus, with the extremity the more remote from the axis of rotation terminating in a pin which works in a groove provided upon the lever carrying the pin. This pin, during the recording process, describes the path that would be taken by the pen of the ordinary recording instrument during the rotation of the cylinder carrying the paper. The recording pen consists of a lever of great length, so arranged that one of its extremities turns upon an axis parallel to that of the recording instrument, but removed from it by a distance approximately equal to the difference in the lengths of the two levers. The other extremity is provided with a groove engaging with the pin of the directing arm, and carries the recording pen at a point a little beyond the groove. In the commercial ondograph the directing arm is 7 in. long, while the lever carrying the pen is double this length. It will thus be understood that while the pin describes an arc of a circle with a short radius, the pen describes one of a long radius. By giving sufficient length to the lever the arc may, within the limits of the width of the cylinder, coincide sensibly with the tangent at the middle point of the arc. Thus, the point of contact of the pen with the paper is but very slightly removed from a generatrix of the cylinder, and the registration is effected with perfect regularity throughout the whole extent of the cylinder. The ondograph may also be used to study a rectified or continuous current. For this purpose the synchronous motor is replaced by a direct drive, effected by establishing an unyielding mechanical coupling between the ondograph and the shaft of the machine to be studied. In a new type of apparatus which he calls the differential ondograph permitting the retardation at will of the period recorded, it is easy to register phenomena occupying from 1/2000 to 1/3000 of a second, but this instrument is intended more for laboratory and research work than for industrial use. A great number of applications of the instrument is described and curves are reproduced showing distorted wave forms of currents from commercial alternators. In order to analyze an alternating-current wave form it is first necessary to determine the

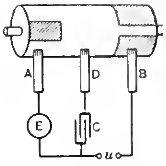

FIG. 3.—COMMUTATOR.

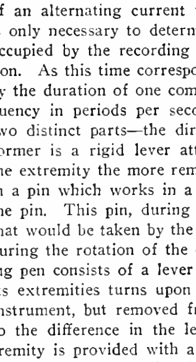

FIG. 4.—CURVE OF HARMONICS.

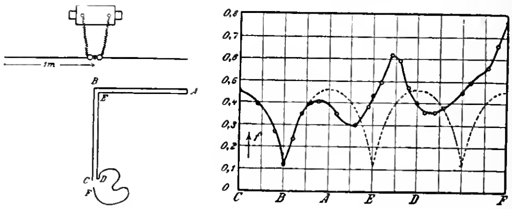
order of the highest harmonics present. This may be done in two different ways. In the first as large a capacity as possible is connected to the periodic potential difference to be analyzed and the curve of the charging current of the condenser is recorded by connecting the ondograph to the terminals of a non-inductive resistance included in the circuit through which flows the charging current of the condenser. This resistance should be as small as possible. By this method the *n*th harmonic is magnified in proportion to its order, *n*, and an indented curve is obtained in which the number of teeth indicates the order of the highest harmonic with the greatest clearness. Fig. 4 shows clearly the discovery of the 15th harmonics in the e.m.f. of a Paris supply current, a harmonic that the sinusoidal-looking potential difference would not have enabled one to predict. In the second method a circuit formed of a highly inductive coil, having as long a time constant as possible, and a non-inductive resistance, is connected to the terminals of the difference of potential to be analyzed. By using the ondograph to record the instantaneous values of the potential difference between the terminals of the self-induction, an indented curve is obtained analogous to that found by the other method. When the order *n* of the highest harmonic is once known, it is easy to trace the fundamental wave and all the harmonics with their several amplitudes, actual or enlarged in a given proportion, as well as their difference of phase relative to the curve under analysis. For this purpose he uses the method of Pupin, which consists in forming a resonating circuit for each of the harmonics.—Lond. *Elec.*, December 11.

Measuring Small Inductances.—STROUD AND OATES.—A description of an apparatus for measuring small inductances. The essential feature is the use of what is substantially an electrodynamometer with laminated iron cores, or it may be briefly described as a moveable coil D'Arsonval galvanometer in which the permanent magnet is replaced by an electromagnet, with a laminated iron core, actuated by a 100-volt alternating current. The solid iron core inside the moving coil of the ordinary D'Arsonval type, is in this instrument also replaced by a laminated one. The instrument is used just like an electrodynamometer when it is arranged for measuring the conductivity of electrolytes. The field magnet is placed across the mains and the highly-insulated movable coil is used to replace the galvanometer in the bridge. The key must be in the battery circuit and under no circumstances should it be in the galvanometer circuit. The apparatus may be used for measuring an inductance with certainty to something well under 1/10 of a millihenry. By adopting a specially sensitive arrangement the author succeeded in reading down to 2 microhenrys.—From *Phil. Mag.*, December; Lond. *Elec.*, December 11.

TELEGRAPHY, TELEPHONY AND SIGNALS.

Multiplication Rod for Measuring Wireless Telegraphy Waves.—SLABY.—A long illustrated article in which he first describes the fundamental experiment on which his "multiplier" for wave measurements is based. Fig. 5 shows an oscillating system generating waves of a quarter wave length of one meter. The waves are received by the loop, *C B A D*, of a length of 4×1 meters. The investigation of the total loop with the spark micrometer gave the same voltage curves across for *A B C* and *A E D* with nodes at *B* and *E* and maximum amplitudes of oscillation at *A* and *C D*. The voltages at *C* and *D* were exactly equal and of the same phase. When a wire, *D F*, of two meter length (one-half wave length) is added, the voltage at the terminal, *F*, is much increased. If the wire, *D F*, is wound in form of a coil, a further appreciable increase of voltage is observed. Whenever a point of maximum oscillation of a conductor is connected with a coil of one-half wave length, the voltage at the free terminal of the latter is increased several times. This is why he calls such a coil a "voltage multiplier." He found later that the addition of such a coil and the form of its connection, as shown in Fig. 5, destroys the symmetry of the oscillation, the dotted line in Fig. 6 representing the symmetrical wave form and the full line, the voltages actually observed along the points, *C B A E D F*. Moreover, the greatest increase of voltage is observed at the terminal *F* if the length of the coil, *D F*, is not exactly a half wave length, but a little smaller. The author then gives some theoretical notes on the condition of resonance. Any earthed conductor of any form may be set into the condition of resonance if the point of the impressed oscillation equals 2π times the square root of the product of self-inductance and capacity of the conductor. This product, which is the deciding factor for resonance, is called by him "oscillation capacity." If it has the right value, there will be resonance whatever the value of the real electrostatic capacity may be. To produce a strong action into the distance, it is preferable to make the electrostatic capacity large; hence, the self-inductance small. On the other hand, for measuring waves, as for instance by the multiplier, it is preferable to make the electrostatic capacity small and the self-inductance large. For this reason the multiplier must be a wire wound in coil form. The wire will be the more suitable for this purpose, the smaller its diameter and the thinner the insulation; for the latter he has found silk insulation very good, but a very thin layer of cellulose-acetate to be still better. The coil is preferably wound on a glass rod which is provided at one end with a metallic coating. Direct-connection of the multiplier with the oscillating system under test, as in Fig. 5, is unsuitable on account of the distortion of the form shown in Fig. 6. The author has, however,



FIGS. 5 AND 6.—WIRELESS TELEGRAPH WAVE MULTIPLIER.

found that such a multiplier coil is brought into the condition of resonance by simply holding it near the oscillating system at a certain distance. The end of the multiplier, which is provided with a metallic coating, is held in one hand of the observer and thus artificially earthed; in the other hand one holds a short, thick earthed metal rod and moves this along the multiplier coil. At a certain position it will be observed that sparks appear at the free end of the multiplier rod; this indicates that the portion of the multiplier coil between its free end and the point where it is touched by the short, thick metal rod is set into vibrations corresponding to the condition of resonance. By artificial means the sparks can be made more easily visible. For practical use he has three multipliers, of 1, 2, 4 cm. diameter for measuring quarter wave lengths between 25 and 50, 50 and 100, 100 and 200 meters, respectively; the length of each rod is 80 cm., and the diameter of the silk-insulated copper wire 0.1 mm.—*Elek. Zeit.*, December 10.

REFERENCE.

Automatic Telephone Exchanges.—MERK.—A rather long communication on the disadvantages of the automatic telephone exchanges, reference being particularly made to an American system. He thinks the main point of inferiority, compared with ordinary exchanges, is the excessive use of an enormous amount of expensive apparatus. He believes that this is not necessarily involved in the design of automatic exchanges, and that in the arrangement of the latter it should be endeavored to approximate more the design of ordinary exchanges. In the automatic exchanges of the present day, the experience obtained in many years' practice in ordinary exchanges has not been taken advantage of.—*Elek. Zeit.*, December 3.

MISCELLANEOUS.

German Electrical Industries.—An article on new industrial amalgamations either completed or in progress, referring especially to the combination of the Allgem. Elek. Ges. and the Union Elek. Ges. The Austrian branch of the Siemens & Halske Company and the Austrian Schuckert Company will also combine. Another amalgamation is that of the Bitterfeld Electrochemical Company and the Rheinfelden Electrochemical Companies. The Berlin-Hagen Accumulator Works Company, which controls the Tudor type of storage battery in Germany, proposes to absorb the Pollak Accumulator Company, of Frankfort.—Lond. *Elec. Rev.*, December 11.

Training Apprentices.—DOWNTON.—An illustrated article in which, as an example of the methods of training apprentices in an engineering works, the system and methods of the Westinghouse Electric & Manufacturing Company are described.—*Eng. Mag.*, December.

New Books.

NOTES ON ELECTRIC RAILWAY ECONOMICS AND PRELIMINARY ENGINEERING. By W. C. Gotshall. vi + 252 pages; illustrated. New York, 1903. McGraw Publishing Company. Price, $2.

The electric railway art, while it is still undergoing radical and striking changes in its essential engineering, has long since emerged from the stage at which a writer in dealing with the subject finds it necessary to go back to the beginnings of history or to indulge in apologetics for explaining the rudiments. In other words, the broad principles of electric traction are as well established, although not so well understood, as those of steam traction; and what has been really required of late is a differentiation in the treatment of the theme. The motors, and the power plant, can be dealt with quite independently and regardless of each other, while neither is in any particular sense related to the engineering of the track and roadbed, or to the economics of the system as a whole. It is, of course, true that there is underlying these topics a deep and close relationship, but the man who would now deal with them all fully and adequately within the covers of one book must lay out a plan encyclopædic in its method and execution. A good deal of such work along the electrical engineering side has already been done, and one could cite standard books which can be studied with profit, and which are an absolute necessity to any engineer working in this field, but so far as we are aware, excepting perhaps an admirable earlier brochure by Mr. E. E. Higgins, there is nothing to compare with this masterly discussion by Mr. Gotshall.

The subject is not only novel but the point of view is also original, and the style of approaching the theme is really something different from what one has previously encountered in electrical literature. We do not know of anything quite the same in electric lighting, in its analogous treatment; and it would be well indeed if the now expanding field of telephony could be subjected to such keen and critical analysis, although some of the articles by Mr. Abbott in our pages have outlined economical considerations too often neglected in that department. Mr. Gotshall happily has looked at the subject first of all not simply as an electrical engineer enamored with armature windings and enthusiastic on rotaries, but as a civil engineer and also as a railroad builder whose broad range of vision compasses these subjects as a whole, and who while not neglectful of these very important points, relegates them to their proper place in determining not merely the style of equipment that is best for the road as seen from the viewpoint of electrotechnics, but that which is best and inevitable when the subject is studied by the banker, the promoter, and that ultimate beast of burden, the investor.

It is remarkable how many lines of study and topics Mr. Gotshall's exposition of the subject opens up. We have the field work not only in its relation to the physical contour of the country through which the road must pass, but the more subtle and more difficult surveys of a sociological character based upon the population tributary to the system, its wealth, its industries, its habits of travel and other data. Passing from these points in regard to cost of construction, the author deals with the operating expenses and the income, and in one valuable chapter the results furnished by existing systems are applied to other possible schedules and conditions. Human judgment is always liable to err, but a given set of facts applied to a given problem ought to work out pretty much the same all the time, and Mr. Gotshall's "template," if it may be so termed, is one to which anything at all corresponding can be fitted and tested. We imagine that Mr. Gotshall's remarks on the risk of employing the percentage of gross receipts method will surprise as well as instruct a good many people. In other chapters of the book also Mr. Gotshall deals with relative construction and operating data, and in a closing chapter the general principles laid down as to proposed installations and their permissible cost are illustrated by an assumed case which represents actual conditions.

In this connection it is well to premise that the keynote of the book is that struck by the modern development of high-speed interurban electric railroading. It would be a mistake to suppose for a moment that the ordinary street railway now limits the scope of electric railway work, and Mr. Gotshall has pushed his practical theorizing boldly into the new domain of interurban work where questions of high speed and low speed and their relative cost and yield are so pressing and so vital. Indeed, a book like this lies at the foundation of the change which is now going on, on short steam roads or short stretches of main lines from steam to electricity, and his analysis of the subject is as applicable to such work as it is to any new interurban road which it is proposed to make electric from the start. The book indeed concludes with a set of complete specifications for the construction of such an interurban system operating over its own right of way. In this field Mr. Gotshall, as those familiar with his career are aware, is peculiarly at home, and the reader realizes that he is being instructed by one who has studied his subject *au fond*.

A remark made at the beginning of this review is not to be misunderstood, for it should be added that the book embraces a great deal of intelligent discussion of such things as motor equipment, rolling stock, storage batteries, power plants, etc., but these are not treated as though they were the "whole thing," but are regarded in their proper place of subordination in a book whose theme is economics. A work of this kind is a good example of intellectual pioneership, which counts as much for the art as a whole as a radical new invention.

The Beginnings of an Industrial City.

Formerly the idea of a town springing up almost over night was entirely associated with the new West, and even now few know that in recent years staid old Western Pennsylvania has been the scene of some of the most notable examples of a Aladdin-like transformation of a countryside into a flourishing town or even city. Jeannette and Charleroi, each with a population now not far from 10,000, are examples of the Western Pennsylvanian method of systematic town founding, by which in the course of a few years farm land is covered with the streets and buildings of a thriving city.

The only likeness with Western town upbuilding is, however, in the element of magical growth. In a thickly settled section where the struggling limits of one town elbow those of neighboring towns, the conditions leading to the creation of new population centers are naturally different from those incident to homesteading. In Western Pennsylvania the making of a new town is purely the result of very definite industrial conditions. The expansion of an industry giving rise to congestion in its old district; increase of cost of living in large communities with its effect on the pay-roll; labor troubles, and above all, desirability of radical changes in manufacturing methods that necessitate the building of a new plant—these are some of the factors that have led to the remarkable town-founding movement in Western Pennsylvania. Yet another striking difference between the Eastern and Western new town is, with respect to its layout and the character of its buildings. Chance does not preside in the location of the different quarters with respect to each other, but the situation of the manufacturing, business and several classes of residential sections are carefully and definitely decided upon while crops are yet growing on the site; and the buildings instead of reflecting the crude ideas of new settlers are architecturally and in modern conveniences thoroughly up to date.

The latest example of one of these new towns is Trafford City, now well underway at what was formerly Stewart Station, about 17 miles east of Pittsburg, and which forms the latest contribution of Mr. George Westinghouse to the material wealth of the section of the country that owes so much of its industrial supremacy to his organizing genius.

The industrial conditions to which Trafford City owes its existence are the result of a situation brought about by the tremendous growth of the manufacturing operations of several of the great Westinghouse interests using foundry products in large quantity. To meet the demands, additions to foundry departments of works long ago ceased to suffice, and until recently the deficiency in castings was supplied from a number of foundries more or less distant from the works, one in fact being located in Cleveland, Ohio. Some months ago the industrial organization known collectively as the Westinghouse Companies, which includes among others the Westinghouse Electric & Manufacturing Company, the Westinghouse Air Brake Company, and the Westinghouse Machine Company, purchased through a subsidiary organization—the Westinghouse Foundry Company—600 acres of land in convenient proximity to the great factories of the Westinghouse Machine Company and Westinghouse Electric & Manufacturing Company, at East Pittsburg, all of which are now connected together and with Trafford City by a private railway of standard railroad gauge permitting the hauling of the heaviest loads that may ever require transportation.

In an article which appeared in these columns some weeks ago, the foundry plant was described in detail, and the present object is to deal more particularly with the town itself. In picturesque old European feudal towns, it is the castle on an eminence which dominates the landscape, the habitations of the retainers clustering beneath in humble array. At Trafford City the real dominating factor—the works—is unobtrusively located in apparent lowly subordination to the living quarters, which are ranged above on terraces giving an inviting prospect over surrounding valley and hill; and owing to the distance to the eastward of the Pittsburg manufacturing district, the atmosphere is free of the smoke which hangs over Pittsburg like a pall. Indeed, had one sought an ideal location for a suburban residence district his steps would have been halted at this spot.

Employers in the Pittsburg district have not been noted for displaying a yearning toward the domestic comfort of employees, as witness on every hand the rough-battened, unpainted houses, characteristic rather of a mining camp than of one of the oldest and, industrially, one of the richest sections of the United States. Mr. George Westinghouse has been an exception in this respect, and while indulging in no experiments toward the betterment of the conditions of the workman's life of the kind that has met with such dire results at Pullman and Dayton, he has ever been solicitous of the welfare of his employees. By these he wishes to be regarded as a friend, but in the manly sense, not as a condescending patron or misjudged as a doctrinaire looking on them as a class to be "elevated."

At Trafford City everything possible has been done that promised to conduce to the domestic comfort of employees, but done in such a manner that one with the most sensitive American spirit could find no cause to feel that he was being patronized or "elevated." The rents, and the prices of buildings offered for sale, are placed on the same basis as if the town were a commercial enterprise, with the difference, however, that the returns on the capital employed are fixed at a point corresponding to an investment in low interest-bearing securities; and the still further difference that owing to the building operations being on a great scale, the cost of houses has been a minimum, and when sold the figure is based on cost price.

The houses are of several different classes, intended to meet the means of any wage-earner, but in every case equal care appears to have been given to the architectural features. All houses are built of brick, and pleasing facades have been obtained by tasteful architectural design apparently involving little or no increased cost in construction. The architect has been particularly successful in the design of the blocks of buildings accommodating two families. A separate entrance at the ground floor for the second story is so skillfully worked into the design of the facade that the appearance of an apartment house is entirely suppressed. The interior layout in this case is no less successful, and the finish, while not expensive, is of a kind to appeal to the neat housewife. Yet the rent of these tasteful homes is even below that of a couple of rooms in a dingy, unhealthy city flat, ranging from but $10 to $12 per month.

Another class of dwellings consists of detached houses of two stories and finished attic, with pleasant yards. We were about to say that these are apparently intended for the more prosperous class of employees, but the rent charged—ranging in the neighborhood of $17 per month—is only about that paid by the average mechanic for vastly inferior quarters a few miles away in the city. In this case the occupant has the option of renting the house or purchasing it outright on the basis of a small payment monthly. Here again are apparent the advantages incident to building operations on a scale sufficient to justify the services of competent architects. There is an absence of the evident straining for effect so characteristic of American middle-class architecture, a light and home-like appearance being obtained by attention to proper proportions and a skillful handling of window and door details.

One of the interesting and the most original features of the town is Trafford Inn, which combines the functions of a hotel, bachelors' quarters and casino. The building is handsomely constructed of pressed brick with stone trimmings, and its interior arrangement is on the bachelor club plan. The Inn will serve as a home for well-to-do employees who have no families, and the charges are fixed at a sum just sufficient to meet expenses. In fact, the rates are such that a bachelor can here reside in dignified state for a sum little or no greater than that paid in a city for hall hedroom boarding house accommodations. On the first floor is a large reading-room, which can be joined to the large dining-room alongside to form a large hall for meetings and entertainments, and the basement is given up to a large billiard room and bowling alley.

The streets of the town are paved with brick and the sidewalks provided with flag stones. The plans for the town include a park system. Though but portions of the site are as yet occupied, what has already been done indicates that in due time a town will be reared on these terraced hills which will vie with the handsomest in the country, and be a Mecca for those who would study an interesting social and economic side of modern industrial development.

English Test of De Forest Wireless Telegraph System.

The British General Post-Office Department has recently tested the De Forest system between Holyhead and Howth, a distance of 64 miles, and using masts 180 ft., which were erected for wireless telegraph experiment two years ago. The De Forest apparatus was installed at the invitation of the post-office officials, under direction of Dr. De Forest and W. M. Horton, his chief assistant, and has now been in successful operation for several weeks.

FIG. 1.—MAST AND ANTENNÆ.

Power at both stations is furnished by small Fairbanks-Morse gasolene engines, belted to a 1-kw, 60-cycle, 500-volt alternating-current generator. The transformers, condensers, tuning helixes, keys, etc., are, as in the standard De Forest apparatus; electrolytic responders are used and telephone receivers. A speed of 30 words per minute was attained during these tests.

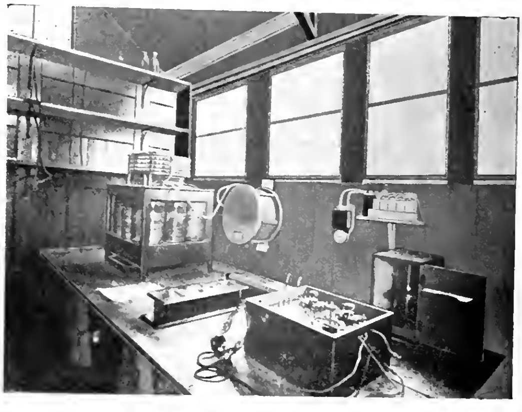

FIG. 2.—VIEW OF INTERIOR OF STATION.

At the invitation of Mr. Gavey and Mr. Lamb, secretary, the General Post-Office officials of the Netherlands Postal Telegraphs were present at the test of December 1, including Mr. De Braum, engineer-in-chief; Mr. Nerstrasz, assistant engineer, and Mr. Kiveron, technical adviser. Several of the officials themselves transmitted and received aerograms with the apparatus and expressed themselves as highly pleased with the facility with which the apparatus could be operated and the messages read.

Westinghouse Turbo-Electric Apparatus for Manila.

An important export order has just been closed with the Manila Construction Company, an American corporation conducting operations in the city of Manila, P. I., for a complete power equipment for the city traction system. The order was secured through Westinghouse, Church, Kerr & Co., and comprises the following machinery: Three 750-kw. Westinghouse turbo-generator units, two compound engine exciter units, one motor-driven exciter unit, three 500-kw. rotary converters, one 300-kw. rotary converter, four 250-kw. oil-insulated transformers, a complete switchboard, one series booster. This booster is mounted on the extended shaft of one of the rotary converters. The car equipments will comprise ninety double outfits of one Westinghouse type, and ten double outfits of another type using standard Westinghouse controllers.

The first turbo-generator unit will be delivered in about nine months. The turbine will operate at 150 lbs. steam, 26-inch to 27-inch vacuum, and 150 degs. superheat. It is fitted with the usual by-pass for securing an overload capacity of 50 per cent. It is also equipped with a quick-closing throttle valve. The turbo-generators will furnish three-phase, 60-cycle current at 380 volts; part of the current will be converted to direct current by the power house railway substation, and the remainder will go to transformers for supplying the high-tension distributing system. The transformers are oil cooled and connected in the two-phase, three-phase, or Scott system for three-phase transmission. The turbine machinery will also furnish current to the local light and power system.

German Three-Phase Transformers.

In the industrial development of polyphase systems in this country it has been customary until recently to provide a single-phase transformer for each phase whenever voltage transformation was required, while on the other hand it has been the custom abroad to install polyphase transformers. The Allgemeine Electricitäts Gesellschaft, of Berlin, which, with its chief engineer, Mr. von Dolivo-Dobrowolsky, has done important pioneer work in the development of three-phase alternating-current engineering in Germany, has built three-phase transformers for many years. A brief description of

FIG. 1.—PARTS OF TRANSFORMER.

the latest types of oil-cooled, three-phase transformers built by this company will, therefore, be of interest.

All these transformers of capacities between 1 and 50 kw are oil-cooled, since it has been found that a much more compact construction can thus be obtained than with air cooling; other things being equal, an oil-cooled transformer has a higher efficiency and a smaller voltage drop than an air-cooled transformer of the same dimensions. Moreover, since oil prevents the windings from coming into contact with air, there is no danger of oxidation. This is a point which does not seem to be sufficiently appreciated by electrical engineers in general. In a Franklin Institute paper of Mr. C. E.

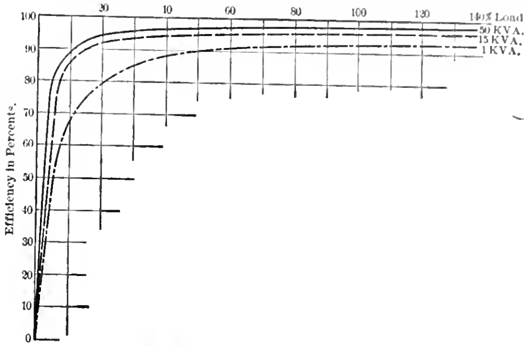

FIG. 2.—EFFICIENCY CURVES.

Farrington on the chemical problems involved in the production of a perfect insulating material for electric machinery, the author points out that while electricians like to claim that their apparatus is well ventilated, they forget that "well-ventilated" also means well oxidized.

All these transformers are built as core transformers with the three cores in one plane. The cores are made up of thin iron sheets covered with paper. As few bolts as possible are used passing through the laminations, and the number of accessory cast-iron parts is restricted as far as possible in order to reduce the losses due to eddy currents, etc., to a minimum. Fig. 1 shows the method of building up the transformer.

The smaller sizes (up to 7 or 12 kilovolt-amperes) and for voltages up to 6,000 on the high-tension side, have concentric windings, the high-voltage winding being at the outside. In the larger sizes the windings are subdivided into smaller coils, the high-tension and low-tension coils being placed alternately side by side on the core. The transformers for 10,000 volts on the high-tension side are built altogether with concentric windings, but the outside high-tension winding is subdivided into a number of smaller coils. As insulating material specially prepared paper is used with a thickness of 0.1 to

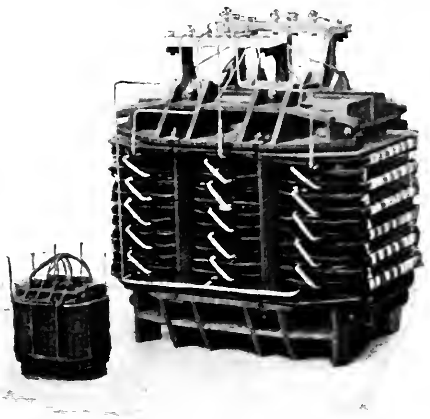

FIG. 3.—METHOD OF BUILDING UP.

0.5 mm., several layers being placed above each other. A thickness of about 0.2 mm. stands 8,000 to 9,000 volts.

The increase of temperature, guaranteed for continuous operation, is 40 to 45° C. in the oil at the top. In general it takes about 15 hours of continuous operation until the maximum temperature is attained. The temperatures of the copper are at the highest 8 to 10 per cent., those of the iron about 5 per cent.

There are three different types of A.E.G. polyphase transformers, namely, for use up to 6,000 volts and for 1 to 50 kilovolt-amperes (type A.D.O.) up to 3,000 volts and for 1 to 52 kilovolt-amperes (type B.D.O.; and up to 10,000 volts for 5 to 50 kilovolt-amperes (type C.D.O.). A diagram giving the efficiency of the first-mentioned type of transformers of three different sizes, as function of the load, is given in Fig. 2.

The above tables give details of the behavior of the three different types.

High Potential Switches.

Fig. 1 is a view of a three-pole, double-break oil switch designed and made by the Hartman Circuit-Breaker Company, of Hansfield, Ohio, for installing on the back of a panel, and to be used on circuits up to 11,000 volts. The view shows the switches in the "off" position with one of the switches enclosed in an oil tank. Each pole of the switch is immersed in a separate tank, which is entirely independent of the adjacent ones and can be readily removed without in any way interfering with the adjacent others. The tanks are lined with insulating material, which is formed in such a way that there is just sufficient space for the free vertical movement of the switches, and the quantity of oil used is thus reduced to the minimum.

A feature of this oil switch consists in the use of the laminated or brush form of contact, which greatly increases the current-carrying efficiency of the switch and also entirely prevents "freezing" or sticking at critical periods. These contacts are protected by final arcing plates, which, with the corresponding plates on the terminal blocks, are removable and can be readily replaced should they become burned away in the course of time. The form of contact which is used and the isolation of the switches in separate compartments gives the switch a very large breaking capacity.

The movable parts of the switch are controlled by means of specially-treated wooden rods, which are fastened at their upper ends to a common cross-bar. They are held in normal position by means of a toggle lock. The switch is opened by giving the handle a slight turn in the direction opposite to that taken in closing. This will cause the toggle to move past the center and the switches will then open free of the controlling handle, thereby producing an absolutely quick break.

In Fig. 2 the switch is shown with automatic overload attachment. There are usually two tripping coils provided for a three-pole breaker, but it can be constructed with a tripping coil in each line. In all cases the operation of any one tripping coil will break all lines.

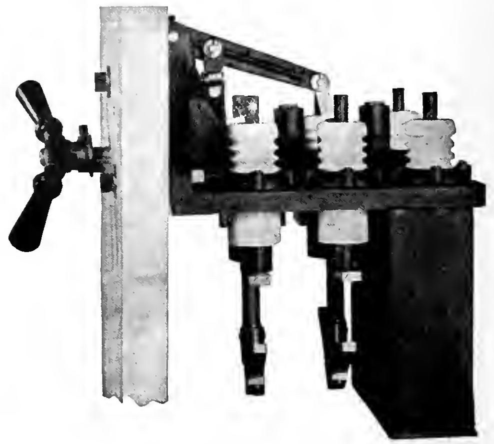

FIG. 1.—THREE-POLE, DOUBLE-BREAK OIL SWITCH.

The distinctive feature of this overload attachment lies in the fact that the tripping coils are energized by current from the high-potential circuit, and the use of series transformers in connection with the circuit-breaker is entirely avoided. The tripping coils, instead of being located on the front of the panel, as is commonly the case, are mounted by means of special porcelain insulators on the

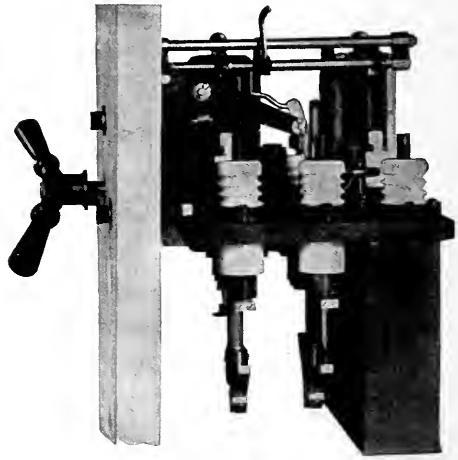

FIG. 2.—AUTOMATIC OVERLOAD ATTACHMENT.

carrying frame itself. They are separated from each other by barriers of insulating material, and the method of insulation throughout is of the highest order. The overload attachment has other distinctive features, one of the most important of which is that it cannot be held closed while an overload exists on any line.

This apparatus is also constructed with remote electrical control, to be installed apart from the switchboard and to be opened and closed from a distance. The operating current may be derived from the exciters, a storage battery or any convenient source of direct-current supply at from 110 to 500 volts. The remote control attachment is said to be very reliable and to add but little to the cost of the installation.

Alternating-Current Signals on Electric Roads.

An interesting system of automatic block signals has been perfected and brought forward by Mr. S. Marsh Young through the Pneumatic Signal Company, of Rochester, N. Y., which is now introducing the invention. Mr. Young, who is well known to our readers, has worked out carefully a method, the details of which are given below, and which have been studied by one of our staff under conditions of actual operation.

The essential features of this system are: 1. The use of alternating current for signaling, and the employment of the traffic rails for the signal circuit as well as for the return power circuit. 2. The use of a special bond for connecting the sections of adjacent blocks around the insulated joints, and also cross-connecting the tracks, which offers little resistance to the direct current, but effectually chokes back the alternating currents. 3. The use of special relays at the entrance of every block, which control the operation of the signals. Fig. 1 shows the arrangement of the apparatus as employed in the demonstration last week. By reference to the cut it will be seen that *X* represents the block rail, *Y* the common rail, *L* the alternating-current transmission line conveying power from *A C*, the alternating-current generator at the station, to the signaling apparatus on the line. The signal blocks are represented in their order as 1, 2 and 3. *T* is the transformer furnishing current for the track circuit to block No. 1, and *T'* performs the same service at block No. 2. *R* and *R'*, respectively, are the relays governing signals *S* and *S'*, while *I J* indicate the insulated joints in the block rail, around which the special bond is utilized, and B_1 and B_2 are similar bonds, which make the block rail

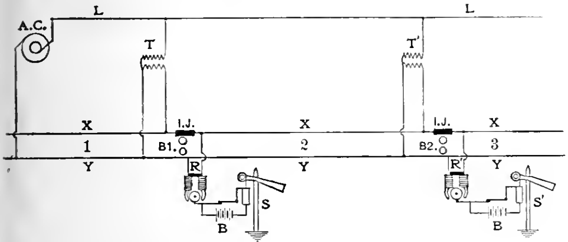

FIG. 1.—DIAGRAM OF TRACK CONNECTIONS.

(*X*) electrically continuous. Fig. 2 shows that portion of the signal mast carrying the case containing the operating mechanism, which can be readily understood. The door of the case is represented open in the cut, thus exposing the mechanism to view. It should be mentioned in this connection that the operation of the system is not limited to the use of this type of apparatus. The operating mechanism consists principally of an electric motor with a train of gear wheels, and an electrical control for making and breaking the connection between the motor and the blades. The motor is entirely enclosed, the commutator end having a glass shield. The power is transmitted through a train of gear wheels.

The principle upon which this system is based is that while it is impossible to keep two direct currents of different potentials separate on the same conductors, an alternating current may be introduced to perform one of two given functions, and if proper apparatus is supplied to keep each current from interfering with the instruments designed to be operated by the other current, the track circuit becomes feasible and practicable. The apparatus must, of course, become operative only under the influence of one current, and must remain inoperative in the presence of any other current, and while it may be called upon to afford a path to the direct current, it must effectively choke back the passage of the alternating current. By this arrangement one current may be used to operate the car, and the other to operate a track circuit to control the signals without interference or interruption.

On a direct-current road, an alternating current is impressed on the direct-current line for signaling, and a road employing alternating current may also be operated if the power current and the signal current have different characteristics. In the test the road employed direct current at 500 volts, and the signaling circuit carried alternating current at 300 volts, which was reduced at the transformers to 3 volts.

In the main power station and in each substation a small alternating-current generator should be placed to provide this alternating current, and in the experimental work on the Sodus Bay Railway a motor-generator was employed. As each block only requires about 20 watts for track circuit purposes, a double-track road, 15 miles in length, with 1-mile blocks, would only require a 1-kw. machine. A No. 10 wire is carried along the entire length of the road for furnishing the alternating current to the signaling system.

It has already been mentioned and shown in the diagram how the divided traffic rail is made continuous electrically as a return path to the direct-current generator, and the other traffic rail is uninterrupted. The track is divided into blocks as it is on steam roads, although but one of the traffic rails is broken for block signaling purposes. The other rail is used as a return for both direct current and alternating current. To one end of each block is fed alternating current transformed to the proper voltage, and at the other end of the block the relay is connected across the two track rails. Between the relay and the track is interposed one of the special bonds, preventing the relay from being affected by the direct current. Between the ends of adjacent block sections are also placed bonds, which offer a free path for the direct current to return to the station, but effectively choke back the alternating current and likewise prevent its escape into adjacent blocks, thus making the operation of the signals in each block independent. While the two traffic

FIG. 2.—OPERATING MECHANISM.

rails are of the same direct-current potential, there is maintained between them a difference of alternating-current potential for the operation of the track circuit of the signal system, but this does not interfere with the operation of the motor circuits. Cross-bonding between the traffic rails or between the block rail and the feeder return is accomplished by the use of devices similar to those used across the ends of the blocks.

In the Rochester exhibition the road was divided into two blocks, one of about half a mile in length controlling the operation of the signals shown, and the other a short block to show that there was no interference between blocks, and that the direct-current return was made continuous through both rails of these blocks.

In the station the motor-generator was operated from a 500-volt trolley circuit, and generated a 300-volt alternating current of 100 cycles. The number of cycles employed was determined by practical considerations wholly, the adoption of this particular standard, for instance, being occasioned by the desire to strike a mean between the ordinary lighting circuit as well as to prevent synchronism between the current-operating signal apparatus and that which will probably be used on the roads employing alternating-current motors.

A No. 10 copper wire runs the entire length of the road, and feeds the primaries of transformers located at the farther end of each block. These transformers are of 100 to 1 ratio, and the secondaries are connected directly across the rails, which sets up a difference of potential between the rails of about 3 volts. The secondaries of these transformers practically take the place of a primary battery on the steam railroad track circuit.

At the entrance to the block was shown one of the relays of special construction, which are only susceptible to the action of alternating current of a proper frequency, while current of different frequency does not affect it. The relay is also independent of any difference of track-current potential that may exist between the rails.

In the demonstration, as has been mentioned, one rail was uninterrupted through the entire length of the road, the other being divided up into blocks corresponding to the signal locations, and insulated by means of standard insulated joints, the same as are employed in steam railroad work. Up to this point the system would present an insulated rail for signaling purposes, owing to the insulated joint between the sections, but this divided rail is made continuous electrically by means of the bond, which is one of the essential features of this system. This bond bridges the insulated joint, and its design and construction are such that while it presents a perfectly free passage for the direct current around the joint it chokes back the alternating current, and thus keeps each block perfectly independent. Similar bonds are placed across the traffic rails in each block.

The signal shown was of the electric motor semaphore type, and operated from the 500-volt trolley line. The resistance, consisting of five incandescent lamps, was interposed between the line and a storage battery of six cells. These lamps were utilized to illuminate the blade, and the storage battery performed the double function of operating as a reserve in case the trolley circuit was cut off, and also enabling the signal circuit to be broken between the points of the relay. The electric motor operated at 12 volts, and took 5 amperes for 5 seconds to pull down the semaphore arm. It was held down by means of a mechanical clutch, taking about .02 of an ampere.

One of the features of the system shown was that even after the insulated joints between the blocks were broken down by a special arrangement, making the polarity of adjacent blocks opposite, the current from one block would rotate the relay in the direction opposite to that which it which normally take, upon the signal circuit, and produce a danger signal. This relay is in reality an alternating-current motor without brushes. Its armature is connected to traffic rails, and its field is energized from the same source of alternating current. It will thus be seen that a car, entering the block and short-circuiting the secondary of a transformer supplying current for that block, will cut off the current of the armature, and thereby cause it to assume its normal position, which opens the local signal circuit.

In operation it was shown that where there was no car in the block the track circuit was completed from the secondary of the transformers through one rail, through the relay and over the other rail back to the transformer. This circuit, when completed, holds the relay points closed, and closes the local signal circuit, which holds the signal to clear. The entrance of a car into a block short circuits the transformer, thereby de-energizing the relay and opening the signal circuit, causing the signal to go to danger. Any interruption to the track circuit from any cause will rob the relay of its current and will result in a danger signal.

It has been the aim of the inventor to have the system so arranged that no possible combination or failure of parts can produce a clear signal when a danger signal should be shown. For instance, the breaking down of the insulated joints between the blocks will result in the giving of a danger signal, and direct-current from any foreign source cannot affect operation, while the presence of stray alternating currents will also fail to operate the relay.

Where electric motor semaphore signals are used, six small cells of storage battery are connected through a resistance to operate the signal motor. The battery also provides a reserve which will operate the signals while the motor current may be off. The battery is charged with about ¼ ampere continuously.

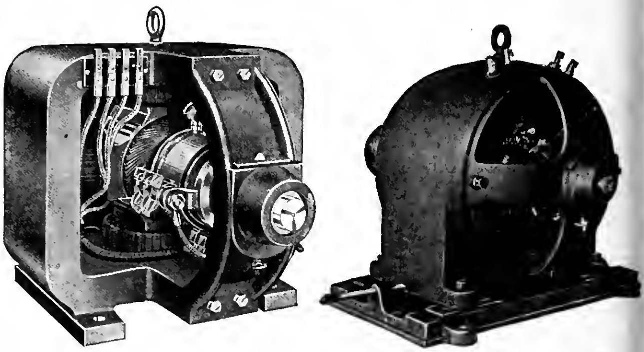
"Ideal" Universal Motors.

The type of direct-current motor illustrated herewith, manufactured by the Ideal Electric and Manufacturing Company, Mansfield, Ohio, is made in sizes ranging from 2 to 35 hp, and in three styles—open, semi-enclosed and inclosed. They can be used for belting, coupling or gearing to the driven machine or shaft, and mounted on the wall, floor or ceiling; the mounting, moreover, can also be changed at the convenience of the user.

The armature core discs are made of very thin armature sheets,

FIG. 1.—ARMATURE.

reannealed after being punched, and then coated with an insulating compound. They are built up directly on the shaft and provided with ventilating openings parallel to the shaft through which air can pass to ventilating ducts between the discs and outer ribbed flange, thus providing thorough ventilation through the entire core and windings. The winding consists of form-wound coils, the smaller armatures being wound with round wire and the larger ones with flat copper strip; the coils are independently insulated, dipped in a special insulating compound and thoroughly baked before being put in place on the armature core, where they are retained in the slots by surface bands. The commutators are made from rolled copper bars insulated



FIGS. 2 AND 3.—UNIVERSAL MOTORS.

from each other by the best grade of amber mica segments. The segments are of unusual length and depth, allowing an ample margin for wear and insuring cool and sparkless commutation. The flanges are of cast iron, insulated from the segments with solid V rings. The commutators are easily removed from the armature shaft.

Exceptional care has been used in the design of the mechanical features, as rigid construction is an important factor in the satisfactory performance of this part of the machine. The brush holders are clamped on the stems close up to the point of brush contact, the brushes being of composition graphite and carbon, and fed toward the commutator through a milled trough in the face of the holder. The brushes are held firmly against the face plate by means of a flat phosphor-bronze spring, brush tension being provided by means of a finger actuated by an adjustable spring. The holder is very simple in design, aside from being reliable in its operation. The brushes operate without vibration, and the machines are practically noiseless in service. The brushes can be readily and independently adjusted, and any brush can be quickly removed while the motor is in operation. The brush contact area is in all cases ample, the current density being at the minimum consistent with economical design. After the brushes are properly set no shifting is required and the motor operates without noise or sparking. The machines are designed to operate at their full rated capacities without the temperature of the armature or field windings rising more than 30° C. and to operate at an overload of 25 per cent, for a period of two hours, and 50 per cent overload for two to three minutes without injurious heating or sparking.

High Power Westinghouse-Parsons Steam Turbines.

The Westinghouse-Parsons steam turbine was commercially introduced in this country several years ago, the sizes then built being of 600 hp nominal capacity, direct-connected to 400-kw, polyphase generators. Subsequent development has been so rapid that within a period of four years turbines of 5,500 kw, or 7,500 hp, nominal capacity, have been designed and are under construction. These machines will have a continuous overload capacity of 11,000 hp, in one self-contained unit, and thus rank among the world's largest prime-movers. Recently marine work has been contemplated by the builders and the near future may be productive of turbines of still greater power, although of slightly different arrangement necessary to adapt the present type to marine usage.

The 5,000-kw turbo-generating unit illustrated herewith is representative of the general type which will be constructed for large powers. This type embodies the experience acquired in the construction and operation of a large number of machines. The principle of operation as well as the general relation and arrangement of rotating and stationary elements characteristic of former types has been employed. The largest machines, therefore, find their direct prototypes in the original design adopted, thus in a measure vindicating the wisdom of adherence to the design of maximum simplicity, viz.: the horizontal single-cylinder turbine.

The most distinguishing features of the new type are the extreme compactness and low speed secured. These features have been practically prescribed by the necessity of minimizing the cost of power building construction for larger station capacities.

The space occupied by the 7,500-hp turbine is approximately 27 ft. 8 in. by 13 ft. 3 in., and the height to the top of the hand railing is 12 ft. This is equivalent to .049 sq. ft. (less than one-twentieth sq. ft.) per electric horse-power capacity, or 20.2 hp per sq. ft. of floor area required. For the complete unit a rectangular area of 47 ft. 4 in. in length and 13 ft. in width is required, which is equivalent to .084 sq. ft. per electrical hp-capacity, or 12 electrical hp per sq. ft. of floor space.

A graphical comparison of floor space required for different types of prime-movers is shown in Fig. 2. In all cases a complete unit is taken as the basis of comparison. This point of relative economy of space is well illustrated by Fig. 3, which represents, in plan, the comparative space occupied by the 5,000-kw Manhattan Railway (New York) engine type units and the 5,000-kw Westinghouse-Parsons turbine units.

In point of speed, the new type fulfils the demand for a unit operating at moderate speed. The 3,000-kw units operate at 750 r.p.m., the 2,000-kw unit at 1,200 to 1,560 r.p.m., and the 1,000-kw unit at 1,500 to 1,800 r.p.m., depending upon the frequency desired. These speeds, although not comparable to engine speeds, do not impose much greater stresses upon the rotating parts, and in addition secure the great advantage of reduction in the bulk, weight and cost of the unit.

The accompanying plan and elevation of the 5,000-kw unit shows the general arrangement of the main cylinder body, bearings and auxiliary parts. The unit rests upon a single bedplate cast in two sections, secured by shrunk links. To the bedplate, which is heavily ribbed to secure rigidity, are bolted the pedestals, generator casing and turbine body, but the bedplate itself is not secured to the foundation by other means than the weight of the unit. Steam and exhaust connections are made beneath the floor level.

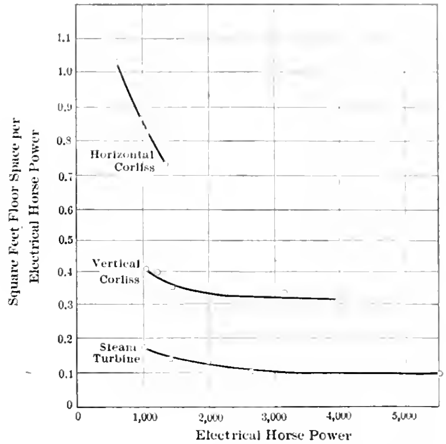


FIG. 2.—COMPARATIVE FLOOR SPACE OCCUPIED BY PRIME-MOVERS.

In the smaller machines of this type the cylinder barrel and both journals are cast in a single casting, thus largely minimizing machine work. In the large machine, however, the barrel is cast in two sections united by links, the outboard section carrying the journal and worm casing, and the inboard section the journal and exhaust opening which extends through the bedplate. As in former types, linear expansion and contraction of the turbine are provided for by a sliding foot. The inboard journal pedestal is bolted securely to the bedplate, but the outboard pedestal is free to slide between parallel machined ways. The main body of the casing is heavily lagged with non-conducting material, secured in place by sheet steel casings.

Leakage of air from the atmosphere into the exhaust spaces of the casing at the entrances of the shaft is prevented by frictionless packing glands. No oil is employed and in consequence the condensation from the turbines is pure distilled water.

In shaft construction great rigidity has been secured with minimum use of metal. A central steel quill carries the entire rotating parts, both blades and balance pistons. Hollow forged steel ends are

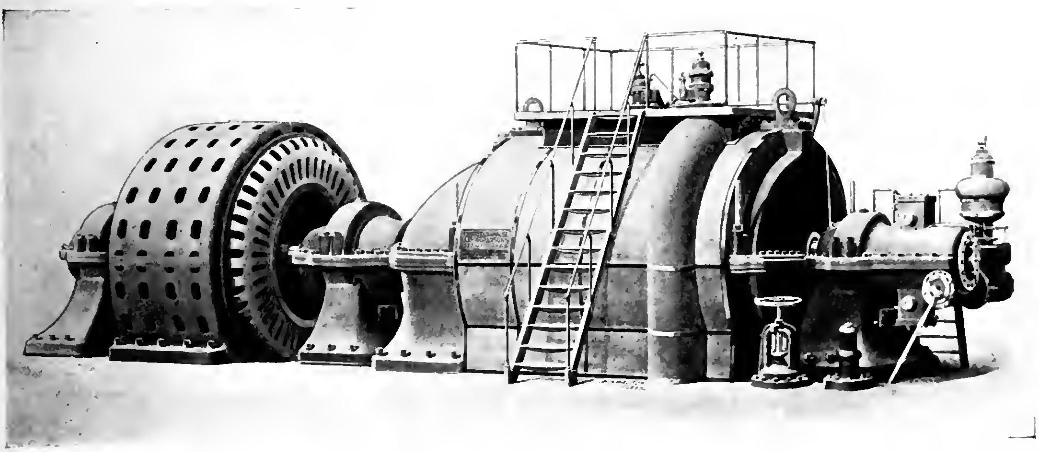

FIG. 1.—5,000-HP STEAM TURBINE.

forced into the two ends of this quill under hydraulic pressure, and are, in addition, secured by arrowhead links. High-pressure steam is conveyed to all parts of this quill structure in such a manner as to eliminate stresses and consequent distortion due to highly superheated steam.

Power is transmitted to the generator shaft through a flexible coupling which is housed partly by the turbine and partly by the generator inboard journal. The coupling is split at the junction of the two shafts, so that by removing one bearing cap and the coupling bolts, either section of the unit may be lifted out without disturbing the adjustment of the remaining section. In the smaller sizes the engagement surfaces of the coupling consist of the squared or hexa-

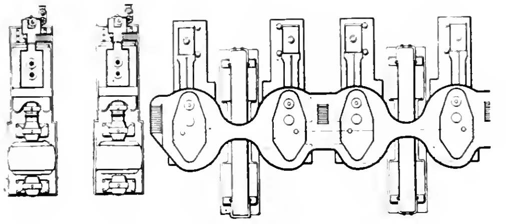

FIG. 3.—COMPARATIVE SIZES OF TWO TURBINES AND TWO RECIPROCATING ENGINES.

gonal ends of the shafts, but in the larger machines a crow-foot sleeve is keyed to each shaft and the power is transmitted by an outside quill engaging the crow-feet. Thus great flexibility is secured, together with the greatest facility in dismantling.

The journals in the larger machines are of the solid self-aligning type, similar to that employed in generators and cross-compound engines. The departure from the familiar oil-cushioned journal employed in the small machines is occasioned by the speed reduction secured. The journal shells are babbitt-lined and are split horizontally, the two halves being united by bolts with shim adjustment. Oil from a central system is introduced at the center under slight pressure, thoroughly flushing all parts. Axial adjustment is provided by metal shims arranged in quarter-box fashion. The diameter of the shaft at the journal of a 5,000-kw machine is 15 in., strikingly small in comparison to the 34-in. shafts required for a cross-compound reciprocating engine of corresponding capacity.

Longitudinal adjustment to preserve proper side clearances is secured by a thrust bearing located next to the outboard bearing. The bearing is not subjected to longitudinal thrusts from the action of the steam and is consequently of small size. The two half shells are advanced in opposite directions by graduated set-screws, so that the actual running clearances are measured in thousandths of an inch. Once set, these adjustments are permanent and do not require frequent "taking up."

Steam enters the turbine successively through an automatic quick-closing throttle, hand throttle, strainer and the main admission valve. A circular port surrounding the entrance to the initial stage conveys this steam to all points so as to avoid stresses incident to more localized admission of highly superheated steam.

An important feature of the steam distribution system is the provision of a by-pass valve. This valve admits high-pressure steam to the second stage of the turbine on overloads in order to increase its capacity up to 50 per cent. in excess of full-rated load. By properly proportioning the by-pass steam to the overload on the turbine, maximum economy may at all times be secured, together with reserve overload capacity. This results in a slight rise in the economy curve on heavy overloads, resembling in some respects the engine economy curve on loads exceeding that of maximum economy. The turbine, however, only suffers in economy at heavy overloads, while the engine economy decreases progressively from 75 to 80 per cent. of full-load capacity.

The main admission valve consists of a double-beat poppet valve, operated by a small piston, this in turn being controlled by a small pilot valve directly actuated by the governor mechanism. The valve admits steam to the turbine in puffs, the duration of which are proportioned by the governor to the load upon the turbine. This intermittent method obviates the throttling of steam to accommodate loading and secures the highest economy by using at all loads steam at boiler pressure.

At the extreme outer end of the turbine shaft is mounted a worm driving a short horizontal cross shaft. This shaft drives at one end the oil pump and at the other the governor through bevel gearing. An eccentric provides the reciprocating motion necessary for the valve mechanism.

The governor is of the fly-ball type, with 90° bell crank ball levers mounted on knife edges and fitted with roller contacts. The governor sleeve and spring is mounted on ball bearings, and adjustment of the spring tension may be made while the turbine is running, thus affording a most simple and convenient means for paralleling alternating-current generators and dividing the load proportionately between them.

At the extreme end of the outboard pedestal is mounted an auxiliary speed limit governor. It is likewise of the centrifugal type and may be set to release, at any predetermined speed, a small plunger valve, which controls with high-pressure steam the operation of the quick-closing throttle before mentioned. This is normally held open by means of an overbalanced differential piston. At the moment the speed limit operates, the excess pressure is removed and the throttle closes. This device is employed purely for insuring absolute immunity from accident from excess speeds, due to the possible disablement of the governor mechanism.

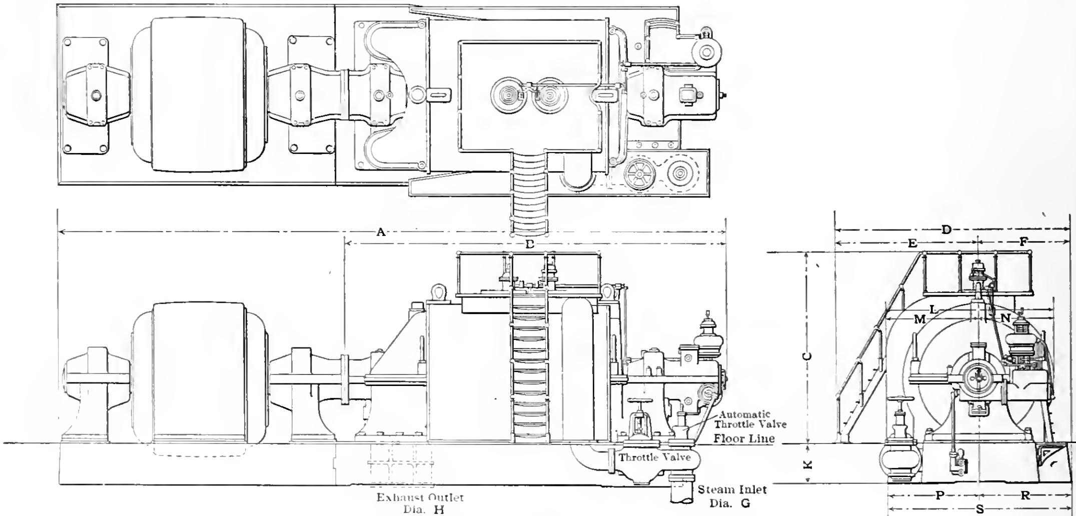

FIG. 4.—PLAN AND ELEVATIONS OF 5,000-HP. TURBINE.

Copious lubrication is supplied to all journals by means of a plunger pump driven from the worm shaft. The warm oil returning from the bearings passes through a copper coil cooler in the bedplate and thence to a reservoir from which the pump draws its supply. The cooled lubricant is circulated at slight pressure, sufficient to insure positive flow. At no point is oil under high pressure employed for preventing erosion of rubbing parts, bearing areas being sufficient for supporting the weight of the rotating parts.

In general construction the 5,000-kw turbo-generators conform to those now building for smaller machines. The field or revolving element is built from a solid cylinder of steel slotted for the reception of the bar windings, and provided with ventilating openings corresponding with openings in the laminations of the stationary element. The generators may be wound for high voltage if desired, in order to avoid the use of step-up transformers in a system of power transmission at voltages ranging up to 15,000.

The 5,000-kw turbo-units here illustrated will be employed in heavy electric railway service, which is the most exacting encountered in central station operation. These machines will form the initial equipment of the Pennsylvania Railroad Terminal property in New York City, operating with electric locomotives the heaviest Pullman trains through the tunnel approaches to Manhattan. Three units will similarly inaugurate the power service on the Philadelphia Rapid Transit Subway system now under construction. Eight 5,000-kw units will furnish power to the London Subway system and three 3,500-kw units to the surface system of the same city. These units will operate under 175 pounds steam pressure, high vacuum and 100° to 175° of superheat.

Terminal Freight Telpherage.

The application of electricity to the unloading of steamship freight at terminals is even more interesting than its use in railroad freight yards, and it is necessary that every electrical engineer should be as thoroughly conversant with the adaptation of electricity to the handling of freight or other material as well as carrying passengers. The domain of electricity is continually increasing, and these later applications proclaim an advent into the great field of railway and steamship freight terminal transportation which has formerly been a "terra incognito" to electrical engineers.

It has always been difficult to handle freight to and from the steamboats, especially when side ports are employed. If the load is to be removed from the hatchways in the deck or from the deck itself, the work was comparatively simple, but the side ports have offered the following difficulties: Low headroom, little width and the rise and fall of the river, due either to freshets or tides, the great variety of the shapes and weights of a miscellaneous cargo.

In unloading, the whole cargo has to be moved through these narrow side ports, then into a narrow space, and then comes the utmost effort to prevent congestion. What is desired is not only to get the cargo out as quickly as possible, but just as quickly to convey it to remote locations in the freight sheds or warehouses. This is most easily accomplished by telpherage. The portable electric hoist draws the loaded truck through the port, elevates it quickly and then the telpher transports at the râte of a quarter of a mile a minute. Therefore, it is the result of the trinity of "telpher, trailer and hoist." It is not sufficient to convey or hoist alone, but each is equally necessary, and the combination of the trailer with the other two gives the perfected result. More than one telpher combination is used, and as soon as one truck is hoisted and the telpher moves from the gang-plank, another telpher waiting upon a side switch near the entrance slips in and the process can be made continuous, for as soon as the loaded truck is at the side of the port the hooks of the next hoist are waiting and ready.

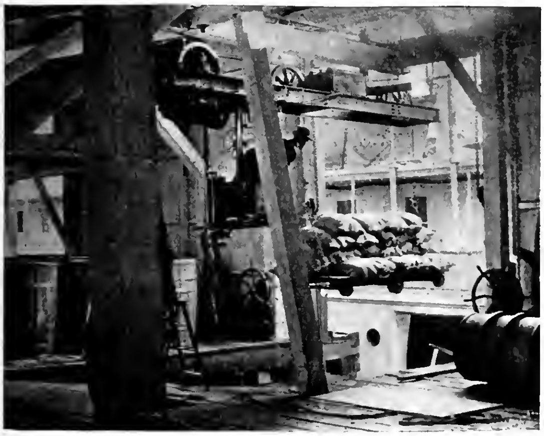

FIG. 1.—RAISING LOAD FROM SIDE PORT OF STEAMER.

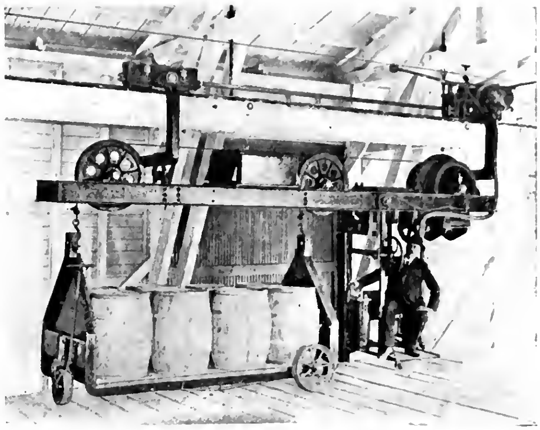

FIG. 2.—BARRELS IN TRANSIT.

In reference to the various views, these are so plain as to need but little explanation. They represent an installation made by the United Telpherage Company for the Old Dominion Steamship Company, of New York, at their southern terminal in Richmond, Va. Fig. 1 shows a load of bags being raised from a side port. Fig. 2 a truckload of barrels passing from the lower to the upper warehouse. Fig. 3 a load of boxes of cheese traversing a curve. Movable cross track can be connected with the side tracks so that every square foot of space can be covered by the telpher. A speed of 1,300 feet per minute is made with loads of 6,000 pounds.

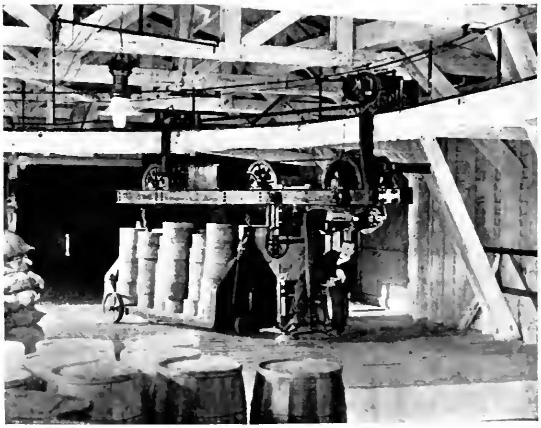

FIG. 3.—LOAD OF CHEESE TRAVERSING A SHARP CURVE.

Alternating-Current Wattmeter Testing Set.

We illustrate herewith a testing set made by the Sangamo Electric Company, of Springfield, Ill., for testing alternating-current wattmeters either in the station or on the consumer's premises, being designed for use on the standard indicating or integrating wattmeter. The purpose of the set is to give a wide range of loads under absolute control with a very small actual expenditure of energy for apparent heavy loads, these being obtained by means of a small transformer forming part of the outfit and enclosed in the same case. For light

FIG. 1.—TESTING SET.

loads, up to 120 or 150 watts, a set of non-inductive resistances and a small water rheostat are provided, also carried inside of the box, each resistance set being standardized for a certain wattage at any desired voltage.

Fig. 2 shows a diagram of connections. The water rheostat is on a third snap switch, and is operated by means of a fibre knob near the front of the box. This rheostat is composed of a heavy glass jar filled with water and made water-tight by rubber gaskets where the brass operating rod passes into it, the rod being moved vertically by

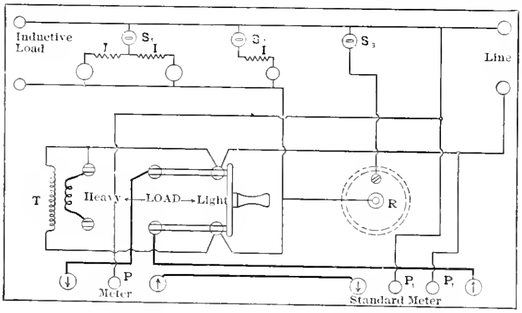

FIG. 2.—DIAGRAM OF CONNECTIONS.

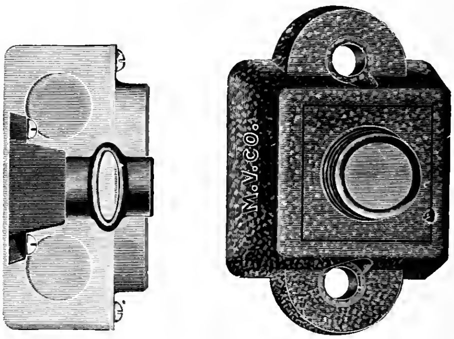
the fibre knob to get any desired load within the range of the rheostat, which is about 5 to 30 watts. On the switch-plate of the set are the three indicating snap switches for the light loads, the various binding posts, the rheostat knob and a double-pole, double-throw switch. For light loads this switch is set in the position marked "light," all connections being then made so that the resistances and rheostat are an actual non-inductive load on the meter tested, the special transformer not being in circuit. For heavy loads, above 200 watts, the switch is thrown over to the position marked "heavy," changing the connections to the various parts of the apparatus. The primary of the small transformer is now in series with the standard resistance and rheostat, which thus become simple controllers for varying the pressure on the primary, giving a range of impressed e.m.f. from a few volts to the full-line pressure.

The secondary of the transformer is wound for two or three volts maximum and large capacity, and is at the same time connected directly to the series coils of the meter and standard wattmeter. These being of very low resistance, the full-load current will flow at from ½ to 1 volt pressure, according to the type of meter under test. Therefore, by varying the primary voltage on the transformer the secondary voltage and current may be varied as desired. The full-line e.m.f. is kept on the shunt coils of the meter under test and the standard in both positions of the switch, and as phase relations are said to be maintained correct by the special construction of the transformer, large loads are obtained with the switch in the "heavy" position with actually less power, so it is claimed, than is used for resistances on light loads. For inductive load, binding posts are provided for connecting an arc lamp, motor or reactance coil, the main switch being set in the "light" position, as the actual load must be used for this purpose. To facilitate the inspection of the water rheostat, the switch-plate is hinged at the back, being held in front by three knurled screws, which, when removed, allow the plate to be swung back without disturbing any connections. The various binding posts are marked with small plates near them, and the only part of the apparatus which needs attention is the water rheostat, which should be inspected occasionally to see that it is full enough, and that the rod is fairly clean.

Insulated Fixture Stud.

A new method of installing a fixture is provided by the Robb insulated fixture stud, which is shown in the accompanying cuts. With the old style the whole would usually project some four inches from



FIGS. 1 AND 2.—FIXTURE STUD.

the back of the box. With the Robb stud and "hickey" only, suppressing the insulating joint, the projection from the back of the box is only about two inches, with the appearance shown in Fig. 2. It allows the use of flat backs on all electrical brackets, as illustrated,

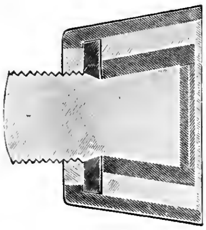


FIG. 3.—FIXTURE STUD.

and affords opportunities for taste and originality in design. As shown in Fig. 3, the device is insulated internally with pure mica, so that not only is the work of putting up fixtures simplified and economized, but a high degree of protection is assured. The appliance is made by the Mitchell-Vance Company, of New York City.

British Westinghouse Annual Report.

The British Westinghouse Electric & Manufacturing Company's fourth annual report issued to the stockholders under date London, December 17, says, in part: "The directors submit herewith the balance sheet for the year ending July 31, 1903, together with profit and loss account to that date, which shows a profit of £107,609.7.6. This includes about £60,000 special discounts allowed by the American companies on orders executed at Pittsburg. It was felt by the American companies that these discounts should be made in view of the fact that the Manchester factory could turn out only about one-third of the electrical apparatus needed for its orders and had, therefore, to purchase the balance from the Pittsburg factories.

"An interim divided at the rate of 6 per cent. per annum upon the preference shares has been paid. After providing for debenture and loan interest and the further items set out on the profit and loss account, a balance remains of £47,106.8.1. Out of this sum the directors recommend the payment of a final dividend at the rate of 6 per cent. per annum on the preference shares, absorbing £45,961.13. carrying the balance, £1,144.15.1, to reserve. This being the first year during which the company's works have been equipped it has not been thought necessary to make any provision for depreciation of buildings and machinery.

"The total authorized share capital of the company has now been issued. Under the provision of the articles of association, the directors have created a further £450,000 4 per cent. debenture stock to rank *pari passu* with the £787,500 previously created; £50,000 of this further debenture stock has already been issued. In order to make provision for maintaining a sufficient supply of stock at the company's works and for other purposes to meet the requirements of the increasing business of the company, the directors will propose to the meeting that an additional 100,000 6 per cent. preference shares of £5 each, ranking *pari passu* with those already existing, shall be created. Arrangements have been made under which the subscription to these shares will be assured. The works at Trafford Park are now employing over 5,000 hands. The following particulars are given as indicating the growth of the company's business: Orders received during the year ending July 31, 1901, £738,000; ending July 31, 1902, £932,000, and ending July 31, 1903, £1,657,114. Among other important contracts obtained during the past year are those with the Admiralty, the Midland Railway Company, the Metropolitan Railway Company, the North Eastern Railway Company, the Underground Electric Railways Company of London, the Buenos Ayres Western Railway Company, the Buenos Ayres Great Southern Railway Company, the De Beers Consolidated Diamond Mines, the London County Council, and the Corporations of Aberdeen, Bath, Bournemouth, Glasgow, Hackney, Ipswich, Liverpool, Salford and Dunedin, New Zealand, and the Savoy Hotel Company, London." It will be recalled that details regarding the major portion of these contracts have been exclusively noted, at the time of placing, in these pages.

The circular issued to the shareholders says, in part: "It has been thought advisable to postpone the annual general meeting until about the middle of January in order that the chairman, Mr. Westinghouse, who is detained in America, may be able to arrive in England and preside."

New High Voltage Oil Fuse.

The high-voltage oil fuse described below will appeal to superintendents of power houses as a means of protection against the damage to switchboards and machines caused by short circuits. This fuse is especially adapted to high-voltage lines and is very simple in construction.

The fuse consists of a glass tube with outwardly flanged ends, a fibre cap at each end being fastened to fibre collars which are held in position by the flanges on the glass. A brass rod fastened to each cap connects the fuse wire, which is made in the form of a link. The glass tube is filled with transformer oil to just above the upper extremity of the fuse wire, rubber washers and discs preventing the oil from leaking out. When the fuse blows, this oil immediately fills the gap caused by the broken fuse wire and forms an effective insulation which will prevent arcing on the highest voltages.

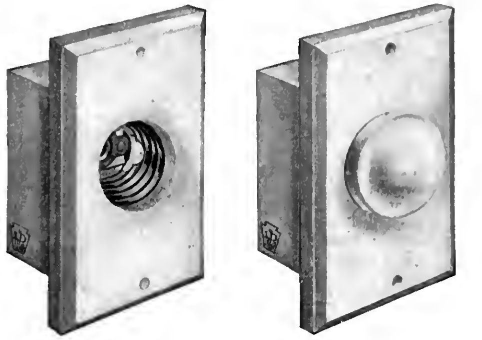
Tests have been made on this fuse by one of the most important plants in Canada, and these tests were evidently of a satisfactory nature, as they have decided to equip their plant with them for 50,-000 volts.

One of the tests is worthy of mention. In order to make a thorough test of its current capacity they used a piece of No. 10 copper wire in place of the ordinary fuse wire and short-circuited the fuse on 2,200 volts with good results. The fusing point of No. 10 copper wire is 300 amp., which on 2,200 volts makes a current of 660 kw. The Anyun Lamp & Electric Company, of Buffalo, is the manufacturer.

Wall Box Receptacle.

A new wall box receptacle is the latest addition to the "P-K" line, made by the H. T. Paiste Co. It is constructed in one piece of porcelain, which prevents any grinding, and affords a "finish" to the plate that never tarnishes or changes. It takes any Edison attachment plug, which makes it available for immediate use in the many places where such a plug is already wired.

As the result of long experimenting, the concern is able to furnish



FIGS. 1 AND 2.—WALL BOX RECEPTACLES.

these receptacles and porcelain cap attachment plugs to match in five most artistic special finishes. Each receptacle is furnished with a special dummy plug which takes the place of the attachment plug when the latter is not needed, thus preserving the neatness of the receptacle.

The two illustrations show the device at a glance. Fig. 1 is a view of the receptacle ready for use and Fig. 2 shows it with a dummy plug in place.

Light and Power in Electricity Building, St. Louis.

Prof. W. E. Goldsborough, chief of the Department of Electricity, has issued data as follows in regard to the light and power service in Electricity Building, St. Louis Exposition:

Regarding the matter of electric service to be available in the Electricity Building during the time of the Exposition, arrangements have been made to supply the following service for commercial use in the above building, namely: 104-volt, 25-cycle, alternating current, 1 and 3-phase; 104-volt, 60-cycle, 1 and 2-phase; 6,600-volt, 25-cycle, 1 and 3-phase; 2,200-volt, 60-cycle, 1 and 2-phase; 2,200-volt, 60-cycle, 1 and 3-phase; 110-volt, 220-volt, and 500-volt, direct current.

For distribution of the above service the following plans have been adopted: 104-volt, 25-cycle, 300-kw available and distributed over entire building; 104-volt, 60-cycle, 100-kw, available and distributed over entire building; 110-volt, 220-volt and 500-volt, direct current, 100-kw, available and distributed over building; 6,600-volt, 25-cycle, 100-kw, available at transformer space only; 2,200-volt, 60-cycle, 50-kw, available at transformer space only; 2,200-volt, 50-cycle, 50-kw, available at transformer space only.

Should any exhibitor require service covered by the last three items it will be necessary for him to wire from his space to the transformer space located in the northwest corner of the Electricity Building. In addition to the service mentioned above, we will have at the transformer space a limited quantity of 340-volt, 25-cycle, one and three-phase, and 400-volt, 25-cycle, one and three-phase. These two items are for supplying current to rotary converters and motor-generators installed in the transformer space.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—There is more strength to the stock market, and a demand for high-grade dividend-paying shares of companies of established credit, as well as for bonds. The United States Steel securities were strong on the better impressions prevailing as to the outlook in the iron and steel industry. Not a little attention was paid to high-grade industrial dividend stocks, such as General Electric. Brooklyn Rapid Transit was a feature, there being further intimations that the money is being raised to carry out improvements in its terminal facilities and power plants with the aid of capitalists interested in other local traction concerns. The transactions in B. R. T. aggregated 156,200 shares, the range of prices being between 50, the lowest, and 53¾, the highest, the closing figure being 53⅛—a net increase of ⅜ point. General Electric and Westinghouse common stand at the head of the list of electrical securities in the matter of net gains, the former closing with a gain of 6 points and the latter 9⅝. General Electric touched 173, but reacted and closed at 171½, the lowest figure being 164½. Westinghouse showed considerable activity, 8,900 shares having changed hands. This stock reached 170 and closed at 168, the lowest figure of the week being 157½. Westinghouse preferred remained practically steady throughout the week, closing at 193, this being, however, a net loss of 2 points. Metropolitan Street Railway closed at 123⅛, ex. div., this being a gain of 3⅛ points. American Telegraph & Telephone gained 1 point, closing at 126, and Western Union ¼, the closing price being 86¼. Following are the closing quotations of December 29:

WESTINGHOUSE BUYS ROAD.—$2,000,000 6 per cent. notes of the Westinghouse Electric & Manufacturing Company have been issued for the purpose of paying in part for the Lackawanna & Wyoming Valley Rapid Transit Railway, which runs from Scranton to Wilkesbarre and other points in Pennsylvania. The road is 42 miles long. In addition to the issue of notes the company took money out of surplus earnings, about $4,000,000, to complete the payment for this property. Westinghouse interests say that the property is worth a great deal more than was paid for it. The object in purchasing this road is to demonstrate what can be accomplished by using electricity for motive power in the transportation of both freight and passengers. The company will begin at once to equip this line with the latest electrical apparatus. It is officially stated that as soon as the Westinghouse Company has equipped the road with electrical equipments arrangements have been already made to sell the property. It is presumed that the company which stands ready to take the property is one of the anthracite coal roads. If the Westinghouse Company deems it advisable to sell the road after it has been electrically equipped and in operation the transaction will show a substantial profit to the Westinghouse Company. The road was purchased from a Philadelphia syndicate and the purchase price has not as yet been stated.

WASHINGTON-BALTIMORE TROLLEY.—It is stated that the high-speed electric railway between Washington and Baltimore, with a branch to Annapolis, Md., already constructed from Washington to Laurel, Md., is to be completed. Cleveland capitalists are at the head of the company. Some time ago it went into the hands of receivers. It was announced that a proposition will be submitted to the creditors for their approval. It is expected that at least $2,000,000 will be required to complete the property, and about $250,000 is needed to provide for debts due. An underwriters' committee has undertaken to prepare a plan for completing the property, and in the meantime calls have been made upon the underwriters to protect their interests by advancing pro rata the sum of $250,000. The plan contemplates the formation of a syndicate, mainly of receipt holders. To facilitate efforts looking to the completion of the property, it is proposed to bring into the control of the committee the receipts representing bonds and stock and all the outstanding bonds and stock not represented by receipts, and to bring into the same control the various committees and boards authorized or elected by holders of stock, bonds, or receipts. The road will be thirty-one miles long.

DIVIDENDS.—The directors of the Mexican Telegraph Company have declared the regular quarterly dividend of 2½ per cent, payable January 14. The directors of the Central & South American Telegraph Company have declared the regular quarterly dividend of 1½ per cent, payable January 7. The directors of the E. W. Bliss Company have declared the regular quarterly dividend of 2½ per cent. on the common and 2 per cent on the preferred, payable January 2. Directors of the Philadelphia Company declared a dividend of 1½ per cent. on common, payable February 1, as registered January 2. It is the regular quarterly dividend. Directors of Westinghouse Electric have declared a quarterly dividend of 2½ per cent. on the preferred and assenting and non-assenting stocks, payable January 11. Hall Signal directors have declared the regular quarterly dividend of 1½ per cent on the common stock, payable January 1.

CINCINNATI GAS & ELECTRIC.—President Kenan reports a good business in 1903. At the end of the Company's fiscal year next spring there will be left after the payment of all dividends and fixed charges a large sum for a surplus fund. This will be a remarkable showing in view of the fact that at the last annual meeting there was a deficit of about $65,000. For the past month the net earnings of the comapny amounted to $26,000 over November of 1902. The increased output of gas for December, as compared with the first 15 days of December last year, was 10,966,000 cubic feet. During the first 15 days of the month the company had applications for 170 new gas connections, as compared with 61 for the same period last year. There was sold thus far this month 117 gas ranges; none last year. There have been secured 106 new electric light consumers, who will use 3,395 incandescent lamps. The company has now 417,785 incandescent lamps in use, as compared with 344,776 this time last year, being an increase of 21 per cent.

B. R. T. EXPENDITURES.—It is stated that the management of Brooklyn Rapid Transit Company has placed the financial needs of the company before the principal owners of the property, and these owners have canvassed the situation well enough to secure definite knowledge that from $15,000,000 to $20,000,000 of cash can be obtained by the company as it needs it, on a 5 per cent basis as a maximum rate. With this knowledge the company is preparing to go ahead with its contemplated improvements. Details of the plans for raising the money will be worked out from this time on. The company appears badly in need of new equipment in various directions.

MEXICAN TELEPHONE reports as follows:

	1903.	1902.		1901.
Sept. gross	$23,024	$20,907	Inc.	$2,117
Sept. net	11,925	9,548	Inc.	2,377
Seven months gross	158,958	139,937	Inc.	19,021
Seven months net	$80,119	$63,131	Inc.	$16,988
Surplus Sept. 30	4,759	4,302	Inc.	457

CUMBERLAND TELEPHONE.—The Cumberland Telephone Company reports for the month of November as follows:

	1903.	1902.	Changes.	
Gross	$314,563	$271,650	Inc.	$42,913
Expenses	177,987	170,960	Inc.	7,027
Net earnings	$136,576	$100,689	Inc.	$35,887
Charges	2,741	23,960	Dec.	1,219
Surplus	$13,834	$76,728	Inc.	$37,106

NORTHWESTERN TELEPHONE EARNINGS.—The Northwestern Telephone Company reports annual gross earnings of $902,802 to State Auditor Iverson, of Minnesota. Of this amount, the State received 3 per cent. as imposed by law, which amounted to $27,084.07.

ILLINOIS TUNNEL COMPANY.—It is announced that the Illinois Tunnel Company has practically completed its plan of taking over the Illinois Telephone & Telegraph Company. The 5 per cent. bonds of the telephone company, amounting to $5,000,000, have been redeemed at 110, and stock to the same amount has been taken up at par. The tunnel company has a capitalization of $30,000,000 in 5 per cent. bonds, and the balance of the bonds will be issued from time to time in extending the underground tunnel railway and freight distributing project. The Illinois Tunnel Company's aim is to act as a steam railway terminal. In doing this, it is expected to carry mail between the post-office and the railways, deliver coal, packages, freight, and all kinds of merchandise.

TWIN CITY RAPID TRANSIT BONDS.—It is announced that the Twin City Rapid Transit Company's directors have authorized an issue of $10,000,000 5 per cent. gold bonds of 1928. At the present time only $3,500,000 will be issued. Of this amount $1,000,000 is to cover expenditures on power plants, sub-stations, equipment and other improvements made in 1903. Another $1,000,000 is to be expended next year to finish the power plant and sub-stations. The remaining $1,500,000 will be used to complete two additional lines between St. Paul and Minneapolis and for the extension of other suburban lines.

MERGER IN PITSBURG.—A merger of the electric lighting and power plants in the coke regions and the Pittsburg, McKeesport & Connellsville Railway system has been effected, and an application for a charter for the combined interests will be made at Harrisburg December 31. It is said the capitalization will be considerably over $5,000,000. The new company, which will be known as the Western Pennsylvania Railways Company, will be in control of the entire lighting, power and street railway system of Westmoreland and Lafayette counties, as well as part of the trolley system of Allegheny County.

TELEPHONE FORECLOSURE.—Judge Swan, of the United States Circuit Court, at Detroit, on December 24, confirmed the foreclosure sale of the Michigan Telephone Company, to N. W. Harris, who represents the syndicate of bondholders and who bid $4,100,000 for the property at the sale of November 5. The petition of Charles Flowers and Samuel T. Douglass, the latter representing the minority stockholders' protective committee, asking that the sale be set aside, is dismissed. The cases will be appealed to the United States Court of Appeals in Cincinnati.

TELEGRAPH EARNINGS.—The Central & South American Telegraph Company reports for the December quarter $286,500 gross and $189,500 net; total surplus, $884,567 against $775,578 last year. The Mexican Telegraph Company reports $129,000 gross for the quarter, $104,500 net; total surplus, $1,430,052, against $1,204,529. The earnings of both companies show a steady growth year by year.

Commercial Intelligence.

THE WEEK IN TRADE.—The principal features were strong and exceptionally active markets for speculatively dealt-in staples, and fair re-orders from jobbers. Business in wholesale lines continues dull, which, however, is usual at this period of the year. Other notable features were the exceptional ease in the money market and the sustained better feeling in iron and steel. The events in industrial lines are the ending of the Colorado coal strikes and the gradual downward adjustment of wages in coal, coke and iron and steel to meet changed conditions of supply and demand. The year is, however, closing in many lines with a rather more cheerful sentiment than appeared possible some time ago. A more confident tone has been brought about in the structural steel market by the reaffirmation of prices for billet, plate and structural steel. Much buying is not expected, however, until after the new year, although Chicago reports that some good quantities of rails have been taken up. In coal a record production, 60,000,000 tons, of anthracite is noted, prices being steady throughout the year. This output is 13 per cent. more than that of the previous record year. 1901. The prices for raw textiles are a drawback, with which the cotton manufacturing trade is struggling. Eastern mills not well supplied with cotton are buying sparingly. In copper extreme dulness prevailed throughout the week, and practically no business was transacted. There is no demand, and consumers are slow in coming into the market. Prices are unchanged at 12⅜@12⅝c. for Lake; 12¼@12½c. for electrolytic, and 12⅛@12⅜c. for casting stock. The business failures for the five days ending with December 23, as reported by *Bradstreet's,* aggregated 243, against 239 the week previous, and 166 the corresponding week last year.

BRITISH TROLLEY RAILS.—A cable dispatch from London, of December 20, says: A rather striking effect of the tariff reform agitation is the determination of the London County Council to revise its policy in regard to the equipment of tram lines, and, instead of ordering rails from Belgium, from which country the lowest bid came, it will buy from a British firm. "The decision," said a member of the Council, "indicates how powerful are the forces working in favor of tariff reform." The decision of the London County Council not to buy Belgian rails is the final outcome of a long controversy. The subject came up on December 8, and a motion to refer the matter to the Highways Committee was adopted. In moving the resolution Col. Rotton said the workingmen of England required to have as much work as they could get during the coming winter, and therefore the question of sending work abroad became a burning one. From information he had received, said Col. Rotton, he found that the wages paid by the firm which was manufacturing the Council's rails were—for foremen, 9d. to 2d. per hour; for what were known as first hands, 6d. to 9d. per hour, and for laborers and all others, 3½d. to 5d. per hour. Were these, he would ask, the rates which were imposed upon English contractors? The Council, said Col. Rotton, had sent two contracts to Belgium representing a total sum of £75,619, about 50 per cent. of that would be paid to the workmen, the other half going for profit and material. That meant that £37,879 had been lost to English workmen. At the rate of 30s. a week that amount would have given employment to 25,610 men for one week, or 485 men for a whole year. Therefore, 485 men had, by reason of this contract, been unemployed for one year in the steel trade of England.

GAS AND ELECTRICITY.—An official of the New York Consolidated Gas Company is quoted as follows: "I wish we had all realized ten years ago how this city would have grown by this time. I think we would have enlarged our plant much more than we did, and those of us who have been interested in the consolidation of the various gas companies would certainly have provided for much more extensive business than we did. This is particularly true with reference to electric lighting. The earnings from our electric light plants alone are becoming the most important part of our business. The consumption of gas for fuel purposes is also becoming a greater factor than ever before. With the incoming municipal administration there is no doubt that our present differences with the city in regard to lighting can be satisfactory adjusted."

BELL TELEPHONE OUTPUT.—The American Telephone & Telegraph Company instrument statement for the month ended November 20 and since December 20 compares as follows:

	1903.	1902.	1901.
Gross output	96,963	93,487	88,497
Returned	32,297	36,838	27,510
Net output	64,666	56,649	60,987
Since December 20:			
Gross output	1,020,941	994,422	867,323
Returned	441,013	420,682	352,173
Net output	579,928	573,740	315,150
Total outstanding	3,730,248	3,099,346	2,467,966

CUSTOMS RULINGS.—It has just been held by legal authority that cable bought in England by the Commercial Cable Company and brought from Hawaii, must pay duty. General Appraiser Hay has handed down a decision on the classification of retort graphite and retort carbon, which are byproducts in the manufacture of gas from bituminous coal. They had been assessed at 35 per cent., as articles in chief value of carbon, but Mr. Hay sustained the contention of E. P. Earle, of New York, the importer, for classification as coke at 20 per cent.

SCHIEREN LEATHER BUILDING.—The Cruikshank Company has sold for Roosevelt Hospital 30, 32 and 34 Ferry Street, New York City, old four-story buildings, on plot 72.5 by 48.5. The buyer is ex-Mayor Charles A. Schieren, the well-known leather manufacturer, who already owned the adjoining property at the southwest corner of Cliff and Ferry Streets, and who will now carry forward the building operation, which he has had under consideration for several months.

OTIS ELEVATORS FOR LONDON HOTEL.—The London interests of the Otis Elevator Company have secured a contract for the equipment of the new Savoy Hotel extensions. The installation, including the eight Otis elevators in the existing buildings, will be one of the largest of its description in Great Britain. The present contract calls for nineteen elevators, comprising five large passenger, four baggage and ten service.

LIGHT AND POWER EQUIPMENT FOR MEXICAN MINES.—La Maria Mining Company, which is engaged in extensive mining operations in the vicinity of Morelia, State of Michoacan, Mexico, is in the market for considerable equipment, including machinery for a lighting and general power plant for its mines. Julio Ambrosino, of Morelia, is the controlling factor in the enterprise.

POWER & MINING MACHINERY COMPANY has issued a circular in regard to its recent changes. The officers are B. Guggenheim, president; Cyrus Robinson, vice-president; H. C. Holthoff, vice-president; Burdett Loomis, Jr., vice-president; B. T. Leuzarder, secretary; L. P. Feustman, treasurer; Hawley Pettibone, consulting engineer. The circular says: We beg to call to your attention that the Loomis-Pettibone Gas Machinery Company, after the recent increase in capital, has now been merged with the Holthoff Machinery Company, of Milwaukee, Wis., under the new corporate name of Power & Mining Machinery Company. We are making extensive improvements and additions to our Milwaukee plant to meet the increasing demand for the American Crossley gas engines, Loomis-Pettibone gas apparatus and Holthoff mining machinery. We shall continue, under Mr. Holthoff's personal supervision, the manufacture of mining, smelting and milling plants and machinery. The Loomis-Pettibone gas producers have established for themselves a world-wide reputation as the only gas producers successfully generating a fixed gas for power and metallurgical work from either anthracite or bituminous coals, coke or wood. The Crossley gas engine, of which there are over 50,000 in operation, and which we are now building as the American licensees, we believe to be the best gas engine on the market. The economies assured by our guarantee to produce power with a consumption of one pound of good bituminous coal per brake hp-hour, or with two and one-half pounds of wood, cannot fail to be of interest to all users of power, for whatever purpose.

HUDSON RIVER POWER LAKE.—A lake larger than Lake George, in which enough water may be stored to maintain the Hudson River at a normal height during the low-water period, is one of the results which the incorporators of the Hudson River Electric Power Company, of Queensbury, expect will follow the completion of their plans. This company was incorporated December 28, at Albany, with a capital of $1,000,000, and having for its purpose the development of the power and resources of the falls of the upper Hudson, and for the distribution of electric power as far west as Utica and Syracuse, and as far south as Hudson. It is expected that the company will build the immense storage reservoir in the Sacandaga Valley, for which the engineers of the Hudson River Water Power Company have been planning for the last two years. The dam and power station will be built at Conklingville, and about 600 pieces of property will be flooded, as well as several small hamlets. The law department of the company has been searching titles and getting options on property for several years, and it is anticipated that by the time permission is asked of the Legislature to construct the dam, the company will own every piece of property to be flooded.

EQUIPMENT FOR APARTMENT HOUSES, ETC.—Percival Robert Moses, 35 Nassau Street, New York, has secured the contract for the equipment of a six-storied hardware factory, which is under construction by Charles E. Ring on Kent Avenue, Brooklyn. The engine will be of 150-hp capacity, from the Fitchburg Engine Company. It will be direct connected to a 75-kw C & C generator. The boilers will be built by the Bigelow Company, 15 Cortlandt Street. Several motors have yet to be purchased. Mr. Moses is to act as engineer regarding the electrical and refrigerating equipment to be installed in the 12-story apartment hotel being built at Sixty-ninth Street and Broadway by the Construction & Spencer Realty Company, McCreery Building, Forty-second Street. It has not yet been decided what equipment will be installed. Plans are now being drawn up, however. An apartment hotel to be built at Eighty-ninth Street and Central Park West, will also be installed with a complete electrical steam and refrigerating plant under the supervision of Mr. Moses.

CURTIS TURBINE FOR MEXICO.—The plant of the Monterey Electric Light & Power Company is to be remodeled and considerably enlarged. The electrical engineering and contracting firm of J. G. White & Co. will undertake the work. Contracts have just been let for the major part of the new equipment, which will have a capacity of about 1,000 kw. A 500-kw Curtis turbine has been ordered. This will be the first large sized steam turbine to be installed in the Southern republic. Two 240-kw belt-driven alternators, one 125 engine-driven exciter generator, and two 7½-kw belted exciter generators, transformers, etc., have also been requisitioned for. The contract was awarded to the General Electric Company, which will also supply 150 fan motors. The boilers will be of Babcock & Wilcox build.

SOME C & C FOREIGN ORDERS.—The C & C Electric Company, 143 Liberty Street, New York, has recently taken various Manchurian, Mexican, Cuban and British orders. A 20-hp slow-speed direct connected motor has been ordered by H. B. Roelker, 41 Maiden Lane, for driving ice machinery in Manchuria. A 30-kw belted dynamo and switchboard has been requisitioned for shipment to Monterey, Mexico, for lighting purposes. A 13-kw generator—belted type—and two motors of 5-hp capacity each have been ordered for light and power use in Cuba. Several orders for motors have come in lately from C. R. Heap, of London.

ELECTRIC TRACTION FOR PROGRESO, YUCATAN.—An electric traction system is to be constructed at Progreso, the prosperous seaport of Yucatan. The United Railways of Yucatan, which operates several steam railroads, has been granted a concession by the municipal authorities. Lines are to be built on all the principal streets. Progreso, which has a population of about 20,000 inhabitants, possesses no means of locomotion to the business center, not even a hack line. The export commission house of Thebaud Brothers, Broad Street, New York, acts as purchasing agents for the United Railways.

EQUIPMENT FOR SAO PAULO.—The daily press reports that the General Electric Company had secured a contract for further equipment for the Rio Tiete water-power plant of the Sao Paulo Light, Tramway and Power Campany, Limited, of Sao Paulo, are premature, as the matter has not yet been decided. The contracts, which will include generators and water turbines, will probably be let shortly after the holidays through the New York offices of the Sao Paulo Company, 29 Broadway. Mr. F. S. Pearson is the principal New Yorker interested.

ELECTRICAL EXPOSITION IN WARSAW.—An electrical exposition is planned to be held in Warsaw, the capital of Poland, between May and September, 1904. The exhibition is to include a special section to be devoted to new inventions. Foreign firms are invited to take part. It is anticipated that exhibits will be allowed to enter Poland free of duty. Interested parties can secure further information from the committee, Philharmonia Building, Moninski Street, Warsaw.

ISAAC L. RICE COMPANIES TO MOVE.—The Consolidated Railway, Electric & Equipment Company, the Consolidated Railway, Lighting & Refrigerating Company, the Railway & Stationary Refrigerating Company, the Lindstrom Brake Company, the Electric Launch Company, the Electro-Dynamic Company, the Electric Boat Company, the Holland Torpedo Boat Company, and Isaac L. Rice himself are about to move their offices from the American Society Building to the Hanover National Bank Building.

MEXICAN TRACTION SYSTEM EXTENDED.—The line of the Campania de Ferrocaniles del Distrito Federal, which are controlled by the Mexico Electric Tramway, Limited, Mexico City, are to be extended. A road is to be built between Tlalpan and Tulpulco and Kochimilco, suburbs of Mexico City. These lines will aggregate about twenty miles. Construction will begin next month. The equipment will be purchased in the United States.

MACHINE SHOP EQUIPMENT.—The Shaw Electric Crane Company, of Muskegon, Mich., has secured a contract for a crane of 30-ton capacity, for installation in the machine shops of the Canton-Hankow railway, which the American China Development Company, 320 Broadway, of which William Barclay Parsons is president, is building in China. A large contract for machine tools, etc., was recently placed with Wonham & Magor, Morris Building.

DEAL IN PENNSYLVANIA.—The electric lighting and power plants in the Connellsville coke region and the Pittsburg, McKeesport & Connellsville Railway system are to be consolidated, and a new company with a capital of $5,000,000, to be known as the Western Pennsylvania Railway Company, will be organized to take over and run the properties.

AMERICANS AFTER MEXICAN WATER POWER.—Americans propose to construct an extensive water power plant in the vicinity of Morelia, State of Michonacan, Mexico. C. C. Place, A. D. Henderson and J. H. Wilcox, all of Oswego, N. Y., are the principal parties interested in the project. They have just returned from a trip to the southern republic.

LIGHTING EQUIPMENT FOR SYDNEY, N. S. W.—Mackenzie, Quarrier & Ferguson, 114 Liberty Street, has secured an order for a 150-hp Harrisburg simple engine, which is to be direct-connected to a General Electric generator of 100-kw capacity for lighting service in Sydney, New South Wales.

CHICAGO GAS ENGINE PLANT.—The Scudder Electric Company, of Chicago, Ill., has just placed an interesting contract with New York concerns. It calls for three 100-kw, C. & C. generators, direct-connected to Nash gas engines, operating on natural gas, for installation in a small, block-lighting, central-station plant.

CONTROLLERS, ETC., FOR ENGLAND.—The Electric Controller & Supply Company, of Cleveland, has secured some fair-sized British orders for its specialties through its London offices, 47 Victoria Street.

EXPORTS AND IMPORTS.—Details of eleven months' commerce of the year 1903 are just made public by the Department of Commerce and Labor through its Bureau of Statistics. They show an increase in practically all of the great groups into which the Bureau of Statistics divides the exports and in all of the groups into which it divides the imports. Agricultural products, as a whole, show an increase of $74,000,000; products of the forests, $10,000,000; products of the mines, $8,000,000; manufactures, $5,000,000, and miscellaneous articles, $2,000,000. In the single group, fisheries, is shown a slight decrease of a little more than $1,000,000. The figures for the month of November show a marked growth in exports of manufactures, the total for the month being $34,093,639, against $30,513,512 in November of last year. Agricultural products also show a marked increase in the month, the figures for November, 1903, being $114,172,255, against $83,035,850 in the same month of last year. The increase in agricultural exports occurs chiefly in cotton, of which the value of the month's exports is unusually high. The increase in exports of manufactures is distributed through many articles, but does not occur, as had been expected, in iron and steel. Possibly one reason is that the gain in bulk does not yet offset the lower prices at which such exports have been made. Total exports for the eleven months are $1,309,000,000 and imports $917,784,000.

MAIL TELPHERAGE IN ENGLAND.—A syndicate has been formed to develop in England the telpherage method of transmitting mail. A syndicate has been formed with a capital of £150,000, divided into 60,000 6 per cent. cumulative preference shares of £1 each, and 90,000 ordinary shares of £1 each. Two-thirds of the amount wanted will be raised in Italy and France, and one-third only in England. The syndicate is formed to take over the patents from Count Taeggi Piscicelli, the inventor, and to develop the system. The directors are the Duc D'Uzes, the Duc de Morny, the Marquis Des Cars, the Comte de Pradere, Sir Theodore Fry, Mr. Charles Edwards, Mr. Henry S. Saunders (a director of the Marconi Company), Count Piscicelli, and Mr. William Digby—the two last joining the board after allotment. England, Italy, France and Spain are represented on the directorate. The Count has nothing more nor less than the later telpherage system introduced of late so successfully by Mr. H. McL. Harding and the United Telpherage Company, who have now three or four score industrial plants in operation. In addition to using telpher motors, it is proposed also to stamp the letters in some way automatically at the drop boxes, but that seems quite an unnecessary refinement.

POWER PLANTS FOR SWITZERLAND.—Among the power stations which are now being built in Switzerland that of Lucerne, in Engelberg-Obermatt, takes a prominent place. Numerous bids were received for this work, and after careful selection by a committee of experts, the plan of the Oerlikon Company was accepted as the best. In consequence, this firm has received the contract for the apparatus for the power station at Obermatt and the substation at Lucerne. The capacity of the station will be 14,000 hp, and current will be transmitted to Lucerne at 27,000 volts over a 18½-mile line. In the Lucerne substation the potential will be reduced to 2,600 volts for transmission to surrounding, districts, including the entire canton of Obwalden. Current will also be supplied for the Lucerne-Engelberg Railway. Several weeks ago the great power station of the Compagnie Vaudoise des Forces Motrices des Lacs de Joux et de l'Orbe was put in operation. This power station will supply over 190 villages in the canton of Waadt with light and power. It will have a capacity of 10,000 hp, deriving its energy from the Lac de Joux Falls near Vallorbe. The alternators will generate directly 13,000 volts at which potential the current will be transmitted.

AUSTRO-GERMAN DEALS.—With regard to consolidations noted in our Digest this week, Mr. J. H. Worman, United States Consul General, at Munich, writes under date of November 5: "A fusion has taken place between the different electric companies of Austria and Germany. The Schuckert Company, of Nuremberg—which was one of the largest industrial enterprises for electricity in Europe, and maintained its branches not only in various cities of the Empire, but also in Austria, with headquarters in Vienna—effected early this year a union with the Siemens & Halske Company, of Berlin, and now a fusion has taken place between the Siemens & Halske Company and the Austrian Schuckert works, so that it may be said that there is at present one trust controlling the trade of both Germany and Austria, for it is proposed to bring under the control of this new combination all the enterprises for electricity in Austria and, of course, in turn, in Germany under one general trust. The capital of this new trust, as far as it covers the control of Austria, is estimated at 18,000,000 crowns ($3,654,000)." That will not go very far for a trust to cover so much ground.

GERMAN CABLE.—The fourth cable line to connect New York City directly with Continental Europe will be completed next year. There is already a German cable starting from the island of Borkum near the mouth of the Ems and extending to this city by way of Fayal in the Azores. The second line takes exactly the same route and has been completed as far as the Azores. The route has been illustrated in these pages. The German Government agreed to pay to the German Atlantic Telegraph Company $178,500 if the line was completed to the Azores by January 1, 1904. In spite of the very unfavorable weather conditions on the Atlantic during the past few months the line has been laid to the Azores and is now in operation between Borkum and Fayal. The second half of the line is now to be laid and the German Government has agreed to pay the company a certain sum if it is completed between the Azores and New York by January 1, 1905.

THE ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, manufacturer of the "Chloride" and "Exide" accumulator, has recently completed arrangements with the trustees of the estate of W. G. Warden, by which the company acquires the entire property situated on Allegheny Avenue, between Eighteenth and Twentieth Streets. The main building on Allegheny Avenue is a seven-story and basement brick structure, having two wings, and containing over 280,000 sq. ft. of floor space. Aside from this building, there are 16 other structures utilized for the different processes of manufacture by the company. The property covers over three acres of ground, and has a frontage on Allegheny Avenue of nearly 600 ft., and is bounded by the Philadelphia & Reading Railway and a branch of the Pennsylvania Railroad, thus giving unusual facilities for the handling of freight and express.

SALES OF TELEPHONE APPARATUS.—Among last week's switchboard shipments reported by the American Electric Telephone Company, of Chicago, are the following: Towner, N. D., one 100-line express; Adair, Ill., one 100-line express; Glenwood Junction, Mo., one 100-line express; Wessington, S. D., one 100-line express; Fairbault, Minn., one 50-line express; Whiting, Iowa, one 100-line express; Kremlin, Okla., one 100-line express; Auburn, Neb., one 540-line installed express; Pleasant Hill, Mo., one 200-line express; Yates, Mo., one 100-line express; Sargent, Mo., one 100-line express; Espyville Station, Pa., one 100-line express; Salisbury, Mo., one 100-line express; Savannah, Mo., two 200-line express; Wolsey, S. D., one 100-line express.

POWER IN SWITZERLAND.—The Motor Aktiengesellschaft für augswandte Elektricitaat of Baden, Switzerland, writes us: "With reference to your article on the Beznau hydro-electric plant in your export issue of November 7, we beg to inform you that the plant in question is owned and operated by our company. We may add that we have installed in Switzerland besides some minor plants the well-known plants at Spiez on the Kander (6,500 hp.), and at Hagneck on the Aare (5,200 hp). We are owners of some important water rights in the north of Italy, the utilization of which we are at present engaged in preparing."

ELECTRICAL EQUIPMENT & SUPPLY COMPANY, of Pittsburg, Pa., will start formally in business on January 2, with headquarters at 215½ Fourth Avenue. It will handle the detail apparatus and supplies of the Westinghouse Electric & Manufacturing Company, General Electric Company, Marshall-Sanders Company, and New England sockets and supplies, and the Shelby incandescent lamp. This list is already being enlarged. The officers of the company are J. H. Waugh, president; Thomas Watson, vice-president; C. G. Hussey, secretary and treasurer.

RAWSON ELECTRIC COMPANY.—It is stated that the Rawson Electric Company, of Elyria, Ohio, manufacturer of telephones and supplies, contemplates erecting a large factory that will employ 300 men. It will also manufacture telephone switchboards and other apparatus. The organization will probably take the form of a consolidation between several independent telephone manufacturers and patentees. Chicago men are prominent in the negotiations which have so far taken place.

MARINETTE IRON WORKS MFG. COMPANY, Marinette, Wis., has built and occupied quite a large factory at Chicago Heights, comprising one machine shop, 60 by 150 ft., one machine shop, 100 by 250 ft.; foundry, 100 by 200 ft.; blacksmith shop, 40 by 60 ft.; pattern shop, 40 by 50 ft.; pattern storehouse, 40 by 50 ft.; power house, 40 by 60 ft., and other smaller buildings, the entire plant being of brick and stone construction.

JAPANESE TRACTION PROJECT.—The construction of an electric railway between Kioto, the ancient capital of Japan, with a population of some 350,000, and Hiogo, another prominent city, is projected. The length of the line will be upwards of fifty miles.

BALL ENGINE ORDER.—The Hocking Valley Railroad has recently placed a contract for three direct-connected units. The Ball Engine Company, Erie, Pa., will furnish the engines.

General News.

THE TELEPHONE.

ELDORADO, ARK.—The Smith Local Telephone Company contemplates remodelling its long-distance lines. One hundred and fifty subscribers are furnished with service, the rates being $1.50 to $2 a month.

EUREKA SPRINGS, ARK.—On the death of the proprietor of the Eureka Springs Telephone System the management of the exchange passed into the hands of his executrix, Mrs. Emma F. Van Allen. She writes us that it is her plan to put in a number of party lines, and to erect a new 100-drop switchboard in the hope of increasing the number of subscribers. A 200-drop Telephone Mfg. Company's switchboard has been operated at this exchange.

FRUITVALE, COL.—The Fruitvale Nutrial Telepbone Company has been incorporated with a capital stock of $1000. The directors are W. J. S. Henderson, D. L. Howard and others.

MACON, GA.—The City of Macon has made a new contract with the Southern Bell Telephone Company by which the latter pays a license of $250 and furnishes free telephones to the city, which will amount to $570 annually.

EGAN, ILL.—The Leaf River & Egan Telephone Company is preparing to build a line through this city.

ATKINSON, ILL.—Henry County Telepbone Company has increased its capital stock from $2500 to $15,000.

CHICAGO, ILL.—The Automatic Telephone Company has increased its capital from $3,000,000 to $5,000,000.

CARTHAGE, ILL.—The East Carthage Telephone Company has been incorporated with a capital stock of $21,000. Directors: O. W. Cutler, C. G. Wright and others.

FAIRFIELD, ILL.—The Egyptian Telephone & Improvement Company has been incorporated with a capital stock of $2500. The incorporators are C. M. Brock, Luke Whitson and J. H. Morian.

COLLINSVILLE, ILL.—The Central Union Telephone Company has a force of men stringing a new telephone line from Centralia to Collinsville, Ill., where connection will be made with St. Louis.

EAST ST. LOUIS, ILL.—The management of the Wabash Railway Company is stringing wires along the right of way for a telephone service. The telegraph system will be kept intact, but it will not be used between local stations except in emergency.

MARION, IND.—The Central Union Telephone Company will spend several thousands of dollars in making improvements in this city.

BLOOMFIELD, IND.—Wm. Hawkins, of Freeman, has asked the town council for a franchise to establish another telephone system at this place.

WORTHINGTON, IND.—The Greene County Telephone Company has been incorporated with a capital stock of $10,000. Directors: W. H. Beatty and others.

DENVER, IND.—The Denver Mutual Co-operative Telephone Company is the name of a new company recently organized by the citizens of this place. The company has contracted for an exchange of business with the Peru Home Telephone Company. The new company has 75 subscribers to begin with.

SAN PIERRE, IND.—The Starke County Telephone Company has incorporated with a capital stock of $5000. The company will install telephone lines and exchanges in Starke, Laporte, Jasper and Pulaski counties. The principal exchange and office will be in San Pierre. Henry A. Smith, T. J. Weinkauff and William Swetzer are the incorporators.

INDIANAPOLIS, IND.—The progress made in telephony in Indiana is shown by the tax record in the Auditor of State's office. Eight years ago there were in the whole state 5677 telephones, independent and Bell together. To-day there are 80,000 independent and 22,000 Bell telephones in the state. That means one telephone for every 25 inhabitants.

CRAWFORDSVILLE, IND.—The Home Telephone Company is arranging to install a new 200-line section to its switchboard. The company will put in a new transfer system on the entire board. Four hundred applicants have been denied service during the past four months on account of inadequacy of the switchboard. The directors are considering the feasibility of putting in about 100 new cables to all parts of the city.

TERRE HAUTE, IND.—The Terre Haute Electric Company is constructing a new system of communication between the interurban cars on the Clinton electric line and the train despatcher of the road, whose office is in the car barns in this city. Instead of having telephones at the switches, as most electric lines have, each car is to have a telephone and when communication is desired a car can be reached at almost any place along the line.

LOGANSPORT, IND.—The Logansport Home Telephone Company has announced an increase in its rates for business telephones from $18 to $30 per year. This increase, however, does not affect subscribers who signed for five years' service when the system was still in course of construction. The company's managers say they have expended a large amount of money in making extensions and improvements and in securing long distance service for the benefit of patrons, and the amount of their investments and the additional cost of maintenance render it necessary to make the increase. The company cites the ordinance which provides that after the company has installed 1000 telephones within the corporate limits it shall have the right to charge for business telepones at the rate above mentioned. The company has now 1700 telephones in service in the city.

WEST UNION, IA.—O. W. Rogers will build a telephone line here in the Spring from West Union to Clermont.

WEBSTER CITY, IA.—The Stratford Independent Telephone Company, which proposes to install a plant in this city, will begin work January 1.

BOXHOLM, IA.—The Grant Township Mutual Telephone Company, of Boxholm, has been incorporated with a capital stock of $10,000. Alfred Sunberg is president and Axel Westeen is secretary.

ELECTRIC LIGHT AND POWER.

TEMPE, ARIZ.—P. E. Fuller, of Mesa, has prepared plans for the power plant of the Tempe Canal Company. The probable cost of work is $200,000.

COMPTON, CAL.—The Compton Water & Lighting Company has been incorporated with a capital of $25,000 by E. E. Moore, C. I. Mason, W. S. Davis and others, all of Compton.

SHOSHONE, IDA.—The Shoshone Electric Light & Power Company, Ltd., of Shoshone, has been incorporated to construct, operate and maintain an electric light and telephone system; capital, $25,000. Directors: Robert Hays, of Pocatello, Frank R. Gooding and Fred W. Gooding, of Shoshone, and others.

STERLING, ILL.—The local electric light company in the spring will expend about $15,000 in improving its hydraulic plant.

SHELBYVILLE, ILL.—The Shelbyville Water, Light & Heat Company has been incorporated with a capital stock of $50,000, for the purpose of establishing a plant in this city. The incorporators are C. C. Scovil, W. H. Beem, Max Kleeman, G. C. Bolinger, I. S. Storm, B. W. Kerr and W. S. Middlesworth. The franchise of the present water company, against which a heavy judgment was rendered at the last term of the Circuit Court and the plant ordered sold by Master in Chancery, expires in August, 1905, and it is the new company's purpose to be ready to do business by that time.

GIRARD, KAN.—The plans and specifications of E. H. Ricksecker, of Chanute, for the electric light plant have been adopted, and he has been employed as consulting engineer.

GALENA, KAN.—W. G. Sargent, of Joplin, Mo., is reported to have purchased water power and mills on Spring River, and the same will probably be developed for electrical purposes.

HANCOCK, MICH.—The City Council has entered into a three years' contract with the Houghton County Electric Light Company to furnish street lighting at $86 per lamp per year.

THREE RIVERS, MICH.—The Three Rivers Light & Power Company has purchased a large strip of land on the Portage River and has commenced excavations for a new channel to give the water a better fall to the power house.

KALAMAZOO, MICH.—C. H. Frisbee, of the Kalamazoo Valley Electric Company announces that his company will, in the spring, begin the erection of two new dams on Kalamazoo River, one near Ceresco and another near Plainwell, to have a combined capacity of about 6000 horsepower. The probable cost will be $500,000.

GRAND RAPIDS, MICH.—The Grand Rapids Edison Company has nearly completed the erection of a dam and power house on Flat river, about 1½ miles north of the village of Lowell, which is 18 miles east of Grand Rapids. The company's business has increased so rapidly that its four plants are insufficient and it is now operating auxiliary dynamos on the power of the municipal lighting plant and some of the local factories. The new plant near Lowell will put the company in good shape to handle all its business and much more. There are two dams, about a quarter of a mile apart. The upper dam includes a number of headgates in a heavy concrete and masonry wall which regulate the flow to the lower dam. This headwater has an eight-foot fall. Below this a turn in the river is cut off by a 35-foot canal cut through a hill, and giving a fall of 22 feet. The main dam is erected at the mouth of this canal, where it enters the river. A circular wall of masonry is utilized at this point. Here two modern headgates 9 feet in diameter and 65 feet in length are located, and in these will be placed the 10 turbines. The power plant is a modern fireproof building with concrete floors and steel roof. It will be equipped with two generators of 450-kw capacity. There will be no transformation at the plant, but the high tension wires will be carried to Grand Rapids, where, at the city limits they will enter conduits extending to the Grand Rapids plant of the company. Here the current will be stepped down to about 220.

MEXICO, MO.—The Mexico Electric Light Company, recently purchased from Macon men by local capitalists, is buying new machinery and adding to the plant in anticipation of installing 24-hour service.

WARRENSBURG, MO.—At a meeting of the City Council the city attorney was instructed to draft an ordinance, submitting to a vote of the citizens of Warrensburg a proposition for public ownership of an electric light plant.

COLUMBIA, MO.—At a meeting of the City Council it was decided to buy the water and light plant owned by the Columbia Water & Light Company. A committee consisting of six business men of Columbia and two experts was appointed to appraise the value of the plant, the city and the company agreeing to accept the decision of the committee.

SEDALIA, MO.—Messrs. James Green, George Blackford, Horace S. and Moses Rumsey, all of St. Louis, Mo., representing all of the shareholders in the Sedalia Gas & Fuel Company and the Sedalia Electric Light & Power Company, voted at a called meeting, held at Sedalia, Dec. 14, to sell the franchises, rights and properties of the two companies to Joseph Clarke and Horace Rumsey. This sale was in furtherance of a merger plan, which practically consummates and by which the Sedalia Gas Company and its plants and the Sedalia Water Company, with its electrical interests and power plants, are consolidated under one management.

RED LODGE, MONT.—The city council has under consideration a proposition to bond the city to raise funds for the installation of an electric light plant. The matter will probably be submitted to a vote of the citizens in the near future. The establishment of a power plant on Rock Creek is also planned by the promoters.

BURLINGTON, N. C.—Electric light bonds amounting to $30,000 have been sold.

CADIZ, OHIO.—The Cadiz Electric Light & Power Company has increased its capital stock from $15,000 to $20,000 and will make improvements to its system.

MANTUA, OHIO.—The Mantua Electric Light & Power Company is installing its new plant and it is expected that it will start operations in the near future.

THE ELECTRIC RAILWAY.

SANTA BARBARA, CAL.—The Edison Electric Company has been granted a franchise to operate an electric railway between Santa Barbara and Summerland, 8 miles south of Santa Barbara.

STAMFORD, CONN.—The New York & Stamford Railway Company will build 50 miles of additional trolley lines in Westchester County. One line will extend to the Fairfield Golf Club, near Greenwich.

BOISE, IDA.—The franchise and holdings of the Boise Rapid Transit Company have been purchased by Cyrus Pierce, Howard Butcher, Jr., and J. W. Anderson, of Philadelphia, for a consideration of approximately $95,000. The new owners of the system have announced their intention of greatly improving and enlarging the service, and will construct a line through South Boise as far as the towns of Star and Pearl.

CHICAGO, ILL.—The Indiana-Chicago Air Line has completed surveys for an electric railway from South Bend to Chicago, by way of Michigan City. A spur from East Chicago to Indiana Harbor is already in operation. This line will connect with sections already built east of South Bend, and within a year it is expected that through trains will be run from Cleveland to Chicago by electric power. Both passenger and freight service are being provided for. The line is controlled by the Stone-Allen-Hanna syndicate of Cleveland, of which Luther Allen is president. The power house for the system between South Bend and Chicago will be located at Michigan City.

INDIANAPOLIS, IND.—The Dayton & Western Traction Company, of Indiana, has filed articles of incorporation. The capital stock is $10,000. The Indiana directors are H. C. Starr and J. R. Robinson, of Richmond. The company is the Indiana branch of the Ohio company of the same name.

VINCENNES, IND.—The following officers have been elected for the Vincennes, West Baden & Louisville Traction Company: Thomas H. Adams, of Vincennes, president; A. Norvale, of Cincinnati, first vice-president; Smiley N. Chambers, of Indianapolis, second vice-president; Fred Chapelle, of Petersburg, secretary; J. O. Davis, of Petersburg, treasurer. It was decided to issue bonds to the amount of $1,500,000, which will be taken by the Municipal Bond & Security Company, of Cincinnati. A trust company of Indianapolis and one at Cincinnati will act as trustees for the road.

LOUISVILLE, KY.—At the regular annual meeting of the stockholders of the Louisville & Eastern Railroad the present officers were re-elected. The proposed extension of the line to Shelbyville was discussed, but nothing definite was decided upon. It was decided to devote the profits of the past year to improvements, instead of paying dividends. A new station will be built at Pewee Valley, which will cost several thousand dollars.

BANGOR, ME.—Plans are now being made for the construction of two important electric railways—one from Bangor to Dexter, a distance of 35 miles, and the other from Rockland to South Thomaston and Owl's Head. The former is to be built by the recently incorporated Eastern Traction Company, of Bangor, capitalized at $180,000, with Forest J. Martin, Charles W. Mullen, Fred T. Dow and H. Franklin Bailey, of Bangor, and W. H. Waterhouse and E. B. Weeks, of Oldtown, as directors. Contracts have been closed for the rails, and ties for the Rockland, South Thomaston & Owl's Head line, and estimates are being made on the electrical equipment and construction. This line may be extended to Port Clyde and Tenant's Harbor, St. George.

MIDDLEBORO, MASS.—At the first corporation meeting of the Plymouth, Carver & Wareham Street Railway Company these officers were elected: Henry S. Griffith, Carver, president; William S. Kyle, Plymouth, vice-president; James B. Collingwood, Plymouth, secretary and treasurer.

FALMOUTH, MASS.—The Cape Cod Street Railway Company held a meeting here a few days ago, at which it was stated that the plans of the company for building its proposed line had been unavoidably delayed. The company will now have to petition the Legislature for an extension of its charter, and will be obliged to ask the Selectmen of Falmouth to extend its franchise in that town.

ALPENA, MICH.—Surveys are now being made for the electric railway which J. W. Boynton proposes to build from South Bend, Ind., to Alpena.

ATLANTIC CITY, N. J.—The Central Passenger Railway Company has applied to the Council for a franchise to construct a crosstown electric railway running from the beach ends of Virginia and South Carolina Avenue to Adriatic Avenue.

NEW YORK, N. Y.—The Jamaica & South Shore Railroad Company, Queens Borough, New York, has been incorporated, capital, $500,000. Directors: W. F. Brown and Joseph Kenny, Brooklyn; F. E. Haff, Long Island City, and H. A. Howarth, New York. This is a re-organization of the New York & Rockaway Railroad Company.

PENN YAN, N. Y.—The amended incorporation papers of the Lake Keuka & East Side Electric Railroad Company show that the capital stock will be $130,000. The directors for the first year are James T. Harris, Joseph C. Harris and Charles H. Hanscomb, of New York; Morris F. Sheppard, William H. Fox and Charles H. Sisson, of Penn Yan; David H. Hoover, of Keuka Landing; Frederick Crosby, of Crosby's Landing, and J. Monroe Shoemaker, of Elmira. The road will run from Penn Yan along the eastern shore of Lake Keuka to Keuka Landing, 12 miles from Penn Yan, and eventually it will be extended to Hammondsport, making the total distance 22 miles.

HAMILTON, OHIO.—The Cincinnati, Dayton & Toledo Traction Company is having preliminary plans prepared for a large central power station to operate the entire system from Dayton to Cincinnati, together with the Hamilton city lines. Current will be distributed through high-tension lines and sub-stations, following the most modern practice. At present the system is operated by five power stations with direct-current equipment. The station will be erected in Hamilton, which is about the load center of the system, and it is probable that present station buildings will be used for sub-stations.

NEW INDUSTRIAL COMPANIES.

THE INTERSTATE RAILWAY TRACTION COMPANY, of Dubuque, Ia., has been incorporated with a capital of $50,000; capital in Illinois, $5000.

THE VESTA STORAGE BATTERY COMPANY, of Portland, Me., has been incorporated with a capital of $1,000,000. Capital in Illinois, $2000.

THE ONE RAIL TRACTION COMPANY, of New York, has been incorporated by Louis J. Somerville, Brooklyn; Harry T. Stresser, Jersey City, and Alfred H. Wilmot, Brooklyn.

THE BUFFALO ELECTRIC CONTRACTING COMPANY, of Buffalo, N. Y., has been incorporated; capital, $5000. Directors: L. Y. Mayer, Joseph B. Mayer and J. J. O'Leary, Buffalo.

THE CINCH CLINCH ELECTRIC SUPPLY MFG. COMPANY, of New York; capital, $200,000, has been incorporated. Directors: J. F. Jacobs, Brooklyn; C. V. Ware and I. H. Lehman, New York.

THE WILMINGTON WATER & LIGHT COMPANY, of Wilmington, Ohio, has been incorporated at Camden, N. J.; capital, $125,000. Incorporators: S. S. Holbrook, G. H. B. Martin and J. F. Cotter.

THE AMERICAN TELEGRAPHOPHONE COMPANY has been incorporated at Washington, D. C., by Stilson Hutchins, Lee Hutchins, Z. R. Babbitt and William J. Dante; capital stock, $5,000,000.

THE OMAHA LIGHTNING ROD & ELECTRIC COMPANY has filed articles of incorporation, the capital stock being fixed at $20,000. The incorporators are S. M. Elwood, B. W. Yoho, J. K. Chalfant and Fred Craff. It will manufacture lightning rods and electric machines.

THE KINGS COUNTY AUTOMOBILE COMPANY, Brooklyn, N. Y., has been incorporated to manufacture automobiles; capital, $10,000. Incorporators: H. Aufderheide, H. W. Palmer, Brooklyn, N. Y.; P. Schissel, Forest Park, L. I., N. Y.

THE WALDORF AUTOMOBILE COMPANY, of New York City, has been incorporated to manufacture automobiles; capital, $500. Incorporators and directors for the first year: F. W. Chapman, L. O. Weilbacher, H. R. Weilbacher, New York City.

THE AMERICAN AUTOMOBILE & POWER COMPANY has been organized at Sanford, Me., to deal in automobiles and machinery; capital stock, $500,000; $50,000 paid in. The promotors are Chester I. Campbell, Samuel E. Ward, Henry C. Long, treasurer, Boston; Everett M. Goodall, Fred B. Averill, Sanford, Me.

LEGAL.

VERDICT FIVE CENTS.—Constable John Small has won a suit for five cents against the Chicago Telephone Company, because the latter did not return five cents on failing to make a connection on a slot machine. The court decreed that the company must return the nickel and pay the costs, which amounted to $7.40.

RIGHT TO MAINTAIN A BRIDGE TO CONNECT ELEVATED LINES.—Judge Honore, of Chicago, has decided that the Union Elevated Railroad Company has the right to maintain a bridge to Rothschild & Company's store from the State Street station. The store and the loop company asked that the city be restrained from tearing down the bridge, and the court made the injunction against the city permanent.

STORAGE BATTERY LITIGATION.—The Electric Storage Battery Company, of New Jersey, has applied to the United States Court for an injunction to prevent the Dayton & Muncie Traction Company from using certain electrical devices on which it claims patent rights. In the complaint it is charged that a regulation system for electric railways and electric power, for which the Electric Storage Battery Company has exclusive rights, is about to be introduced into the traction company's power houses, and it asks that it be prevented.

THE DEADLY NON-GROUNDED LOW TENSION CIRCUIT AGAIN.—The Oshkosh Gaslight Company and the Oshkosh Electric Light & Power Company, Wis., have settled for the death of Olive Oaks, a young girl who was killed while turning on an electric light in her home last year, by paying her parents $1400, suit having been brought for $5000. A cross of wires during a sleet and wind storm grounded a 3500-volt circuit through Miss Oaks as she stood on an iron heating register in the act of turning a switch. The plaintiff based suit on the alleged defect in wiring.

DAMAGE BY ELEVATED ROADS.—In New York City, the Cooper Union has just had a large award in its favor against the Manhattan Elevated for damages. The amount is $130,000. In Boston, the first verdict in the numerous damage suits brought against the Boston Elevated Railroad Company was returned recently in the Superior Court for Suffolk County, a jury deciding against the road and fixing damages at $9938. This suit was brought by a trustee of buildings situated near the elevated structure in the South End to recover $30,000 for alleged injury to property through noise, dust, and invasion of the occupants' right to privacy consequent upon the operation of trains. Other suits to recover damages of more than half a million dollars are pending.

MULTIPLE VOLTAGE DRIVE.—The Bullock Electric Mfg. Company, by Mr. L. Lowenberg, secretary's office advises us as follows: "The Bullock Electric Mfg. Company's claims to the exclusive rights under the Ward Leonard patents to install multiple voltage system of electric drive for operating machines is sustained. This decision was rendered by Judge Kirkpatrick, of the Circuit Court, Dec. 2, 1903, in the suit of the Bullock Electric Mfg. Company, of Cincinnati, Ohio, vs. the Crocker Wheeler Company, of Ampere, N. J. This system provides the only successful means of operating and controlling motors driving machinery which requires variable speeds. This opportunity is taken of warning intending purchasers of multiple voltage apparatus that the Bullock Company will vigorously protect its rights under the patent."

Obituary.

MR. JOHN H. GRAHAM.—The many friends of the senior member of Graham Bros. Company, Hudson Street, New York City, are grieved to note his death on Dec. 13, after a long and busy career, largely devoted to electrical industries. Until the last few years he had been constantly engaged in the electrical field since 1877 and took a keen interest in its development. In the year named he was with Mr. (now Sir) Hiram N. Maxim. He was connected with the Brush Electric Company, 1879-80; the old United States Electric Company; the Schuyler Electric Company and the Waterhouse Electric & Mfg. Company; and then engaged in the construction and repair business. He was of a cheerful and sunny disposition and was widely esteemed. He was a Mason. During the past few years, his health declined rapidly. The body has been cremated in accordance with his wishes.

Educational.

FREE LECTURES.—The New York Board of Education is continuing next year its admirable free lectures under Dr. H. M. Leipziger, and the courses for January and February include lectures on electricity by Messrs. W. W. Ker and Mr. T. I. Jones, who have courses of eight and eleven lectures on the subject.

COLUMBIA UNIVERSITY, N. Y.—A number of investigations of considerable interest are being carried on in the newly established Phœnix laboratories for advanced research in physics at Columbia University. Professor Nichols is occupied with several investigations on the behavior of a charge of static electricity in the magnetic field and the possibility of producing a drag in the lines of static force. Dr. Pegram is working with Professor Nichols on his investigations, and is also studying the ionization of gases by heat, and studying various phenomena connected with radium and other radio-active materials. Dr. Davis is continuing his investigation on the effect of ionization on the radiation of luminous gases, and is also working with Mr. Hendren on the rate of re-combination of ions in high vacuo. Dr. Davis and Mr. Wheeler are investigating the minimum velocity of cathode rays necessary to produce x rays. Professor Parker, Dr. Day and Messrs. Fountain and Blake are also carrying on electrical investigations. Mr. Trowbridge is investigating the peculiarities of the electrodeless discharge at very low temperatures, in an endeavor to throw some light upon the peculiar phenomena which accompany the passage of certain meteors, whose trail remains visible for a long time after the stone has actually passed. Miss Stone, of the department of physics at Vassar College, who devotes her Saturdays to work in the Columbia laboratories, is continuing her investigations on thin platinum films deposited by the cathode discharge in vacuo. She has succeeded in developing some very interesting phenomena that promise to have an important hearing upon the structure of the cathode discharge.

Personal.

CAPT. W. L. CANDEE, joint manager of the Okonite Company, has returned from a short trip to Europe.

MR. H. WARD LEONARD has, we regret to state, been confined to the hospital at Bronxville, N. Y., on account of trouble with one of his eyes. It is hoped and believed that he will soon be convalescent.

MR. T. F. MANVILLE, president of the H. W. Johns-Manville Company, started for the West on Dec. 22, and before returning to New York will visit the company's branches in Milwaukee, Chicago, St. Louis and New Orleans.

MR. SAMUEL PUTNAM AVERY offers, in memory of his son, Henry Ogden Avery, a prize of $50 for an electrolier, suitable for a newel-post in the hall of a public library. The design must represent a single female figure, draped.

MR. I. STERNFELD, the recently appointed general manager for G. & O. Braniff, Mexico City, which represents the Westinghouse interests in the Southern Republic, is at present in New York at the export offices of the Westinghouse Company, Hanover National Bank Building.

MR. W. J. BRYAN, former Democratic candidate for the presidency, has been touring Europe amongst the royalties with great eclat. He contributes to the *New York Journal* an article on the marvellous benefits from municipal ownership. What Mr. Bryan does not know on the subject would fill a library.

MR. EMILIO DYSTERUD, general manager of the Monterey Electric Light & Power Company, who has been in the States for several months past, will leave very shortly for home. The plant is to be remodeled and largely added to. Mr. Dysterud, while here, may be found at the Federal Electric Company, Washington Life Building.

MR. A. W. BUCKS has taken the management of the Chicago office of the Electric Machinery Company, of Minneapolis, Minn. This office is at the Ellsworth Building, 353 Dearborn Street. The apparatus he will handle comprises direct current motors and generators, and inductor type alternating current generators.

MR. W. J. WILGUS, fifth vice-president of the New York Central Railroad, has just returned from a six-weeks' trip through England, Scotland, France, etc., studying electric railway practice and particularly railroad terminal facilities. He does not appear to admire the methods of the Paris Underground any more than he does the jagged skyscraper outline of New York thoroughfares.

MR. H. L. SHIPPY, of John A. Roebling's Sons & Company, who has recently been ill with appendicitis has recovered we are very glad to say, and has so far convalesced as to be able to visit his office last week. For his friends, his return to health and strength has been one of the pleasures of Christmas and all have joined with special heartiness in wishing him a happy New Year.

MESSRS. H. HINE and Leonard C. Curtis, who have been in New York for several days past conferring with Mr. Charles A. Coffin, president of the General Electric Company, and John Hays Hammond, regarding new power transmission projects of the Guanajuato Electric Light & Power Company, in which concern all are largely interested, have left for Colorado Springs whence Mr. Hine will go direct to Mexico.

PROF. A. G. BELL.—Private dispatches received from Prof. Alexander Graham Bell state that he expects to return to Washington from Genoa on Jan. 15 with the remains of James Smithson, the English founder of the Smithsonian Institution. Prof Bell offered three years ago to bring the remains of Smithson here at his own expense, and renewed the offer last Spring. The action is taken with the sanction and authority of the Regents of the Smithsonian Institution. It is expected that there will be no opposition to the removal of the body. The removal of the remains at this time is desirable because a stone quarry has encroached on the English Cemetery at Genoa to such an extent that it has become necessary to move the bodies buried there.

DR. C. H. SHARP.—Dr. Clayton H. Sharp, engineer of the electrical testing laboratories of the Lamp Testing Bureau, New York City, has returned from an interesting trip to Europe, where he visited all of the principal electrical laboratories. Dr. Sharp gathered a mass of data and information which will enable him to fit up the new laboratories of the company at 80th Street and East End Avenue with the most complete and up-to-date apparatus and by the best methods known. He carried with him a number of carefully prepared standard photometer lamps, which were compared by the principal photometrists of Europe with their authorized standards, and found to be in extremely close agreement with the best of them. The Lamp-Testing Bureau will probably occupy their new laboratories in January, 1904.

HON. WILLIAM I. BUCHANAN, who was recently appointed by President Roosevelt to the post of Envoy Extraordinary and Minister Plenipotentiary of the United States to Panama and who left about a fortnight ago on a special mission to that part of the world, will return within the next few weeks for the purpose of taking general charge of the various Westinghouse interests in Europe. Mr. Buchanan was appointed in 1894 United States minister to the Argentine Republic, and served there until 1900, when he returned to this country and became director-general of the Pan-American Exposition. After his duties at Buffalo had ended he went back to the Argentine Republic to settle up some affairs for the United States. Until recently he has acted as South American agent of the New York Life Insurance Company.

MR. C. H. WILLIAMS.—A report that will be one of the most prominent and most useful features of the 27th convention of the National Electric Light Association, to be held in Boston next May, will be that of Mr. Charles H. Williams, of Madison, Wis., editor of the "wrinkle department." Mr. Williams has sent out to members a circular letter, asking each of them to make at least one contribution to this report, in the shape of a description of some method not in general use in connection with the manufacture, distribution or sale of electric energy, by which some difficulty has been overcome or some result obtained. A few sample "wrinkles" were sent with the letter, showing the general character of information desired and the style in which it should be formulated. A good many replies have already been received, and Mr. Williams is encouraged to believe that his report will be very successful.

MR. CHARLES R. PRATT has opened an office at 160 5th Ave., New York, as consulting engineer. He intends to work along the lines of general electrical engineering, while making a specialty of elevator and escalator work as well as advising in new ventures as to shop cost of construction of new apparatus and cost of machinery, machine tools, etc., to be installed. Mr. Pratt's long connection (24 years) as superintendent and engineer of some of the largest machine shops in the country has given him valuable knowledge in this line. Mr. Pratt was with the Sprague Elevator Company for years and aided in the development of the Sprague elevator, which is in such general use to-day. For the last few years Mr. Pratt has been with the Marine Engine & Machine Company, Harrison, N. J. His work in the electric elevator field has been highly successful and has besides given him an intimate insight into the solution of electrical problems.

DR. GEORGE F. KUNZ, who has been making a careful study of radium, was puzzled by the first report which came to him concerning "solium." The phenomenon described from Paris did not seem to him to be natural, and he was not one of those who spent much time searching for the new element in this country. Instead, he caused an investigation to be made, and he has just received word which confirms what he has believed all along to be the case, that there is no such element as "solium." "I have just received an answer to some questions sent by me to Paris," says Dr. Kunz, "and I am not surprised to learn that 'solium' is not an element, but a hoax. Research has been made by M. Guillaume, director of the International Bureau of Weights and Measures, and the admission has been made to him that the 'discoverer' of 'solium' merely took advantage of the wide interest in radio active substances to perpetrate a joke on the world at large."

MR. F. E. KINSMAN, in a letter to the *New York Times* on third rail dangers, says: "The cheapest and at the same time the most practical plan consists of returning the current by the furthest away traffic rail, reinforced by such return feeders as circumstances require. They need be no larger than the "third rail," nor any more heavily bonded than is now provided for the outgoing "third rail," thus eliminating the use of the traffic rail nearest the "third rail" as a return conductor. Insulating it sectionally increases the safety factor of this arrangement. It will be readily seen that the chances of a short circuit between the "third rail" and the return conductor are thus reduced by the square of the distance, which in the present practice would be between five and six feet. A person cannot step or reach across this space without unusual effort. The tools of the workmen should not be long enough to bridge this distance. The dropping of a piece of metal across the near-by rail would produce no dangerous effect, unless there was a car in the section while the accident occurred, which is unlikely, owing to the disposition to avoid the track near a moving train. The arrangement also admits of train signaling and control along the lines now being considered without use of alternating current."

Trade Notes.

PITTSBURGH TRANSFORMER COMPANY, of Pittsburgh, Pa., has issued a charming "Pretty Girl" calendar for January, the name of Mr. A. H. Mustard, New York agent, appearing on the copy that reaches us.

MR. RUSSELL HOWLAND, the advertising expert, etc., has moved from 150 Nassau Street, New York City, to 120 Liberty Street, in order to secure more room and be near many of his clients in the machinery district.

THE PHELPS COMPANY, Detroit, Mich., the maker of Hylo lamps, is putting out a colored glass sign which reads "Electrical Supplies," and is lit by one of its self-flashing sign lamps. A very attractive effect is thus produced.

G. M. GEST, the conduit contractor, etc., has issued a large and handsome calendar for 1904, the illustration on which is a double manhole built by him for the Louisville, Ky., Railway Company. The background card is a Pompeian red.

COMMERCIAL ELECTRIC COMPANY, Indianapolis, Ind., has just issued a very interesting little folder giving the exact figures of cost for properly installed isolated plants of 65,100 and 140 incandescent lights, so that a man can tell in advance what an equipment is likely to cost him.

LAMPS ON WILLIAMSBURG BRIDGE.—The incandescent lamps (20,000 in number) used to illuminate the new East River bridge at the opening last week were furnished by the Munder Electric Company through its sales agent, C. J. Purdy.

LOOMIS-PETTIBONE GAS MACHINERY COMPANY, of 52-54 William Street, New York City, has recently opened branch offices as follows: Boston, State Mutual Building; Pittsburgh, Farmers' Bank Building; Chicago, First National Bank Building.

MANHATTAN ELECTRICAL SUPPLY COMPANY, New York and Chicago, has issued special new price lists and trade literature, including clearance lists of the New York store, electrical portable lamps of handsome design, and other specialties.

THE MECHANICS SUPPLY COMPANY, 96 Peter Street, Quebec, Canada, is introducing at a trivial price two charming little novelties for the new year, one being a tiny wrench and the other a dainty hammer. Both of them "work" perfectly. They are well made and heavily nickeled.

AUTOMOBILE WORK.—The Edison Electric Illuminating Company, of Boston, has recently issued a most interesting bulletin giving an account of the recent round trip with an Edison battery automobile, between Boston and New York. Another bulletin gives a list of charging stations available all over New England.

AUTOMATIC TELEPHONY.—Contractors will be interested in the descriptive matter issued by the Electric Appliance Company, Chicago, telling of its latest things in telephones of all kinds. Circulars can be had for the asking, giving full details of the new Dinsmore automatic telephone for inter-communicating work.

STANLEY AND NORTHERN.—The Stanley Electric Manufacturing Company and the Northern Electrical Manufacturing Company announce that they have established branch offices on the Pacific coast with headquarters at 69-75 New Montgomery Street, San Francisco, Cal., and sub-offices at the Pioneer Bldg., Seattle Wash., and the Douglas Bldg., Los Angeles, Cal.

THE MONSON BURMAH SLATE COMPANY, of Portland, Me., has received the highest kind of endorsement for its slate, both as to durability and adaptability for all electrical appliances and for the beauty of its finish, it being of uniform color and unfading black. The slate which it furnishes has a very high insulation test and is wholly free from moisture, absorption and metallic substances.

PASS & SEYMOUR, INC., Solvay, N. Y., have in press an edition of 25,000 catalogues to be distributed on Jan. 1, 1904. Anyone interested in the P. & S. specialties should drop a postal card to the firm when a copy will be mailed promptly. This catalogue shows a number of valuable and useful additions to the P. & S. line, as they have brought out many new specialties during the past year.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., reports a very gratifying business for the outgoing year of 1903, and asserts its belief that 1904 will witness still further improvement and development of its already immense business. The company states that it will continue to push with vigor the same specialties with which its name is already so well identified: viz. "Okonite" and "I. X. L." wires, "D. & W." enclosed fuses and safety devices, "Pittsburgh" transformers, and "Columbia" lamps.

THE WEBSTER CHEMICAL COMPANY, St. Paul, Minn., is manufacturer of Crystal Chemical Coloring, a compound for artificially coloring incandescent lamps. The material has been on the market for a number of years and the maker claims that it has never known of a case where it has not given complete satisfaction. It is said to remain good for a long period of time. Very pretty colors are secured, in addition to which there are opal, white and ground glass effects. The use of this compound is a convenient method for securing an attractive illumination without the expense of natural colored bulbs.

THE ECONOMICAL ELECTRIC LAMP COMPANY has issued a circular to supply dealers throughout the country in which the good points of its turn down lamp are attractively set forth. It dwells on the simplicity of the "String Pull" lamp and its positive action, on the saving of current when the smaller filament is burning, and on the fact that the lamps are furnished in various bases for differing voltages. The catch phrase employed by the company "Don't burn your hands" is emphasized by an illustration showing its needlessness when "Economical lamps" are used.

THE SMITH & HEMENWAY COMPANY has contracted with the Page Storms Drop Forge Company to handle the entire marketing on its engineer's wrenches and hereafter the latter concern's New York office will be 296 Broadway, care of the Smith & Hemenway Company, which will look after this end of its business exclusively. In addition to manufacturing drop forged engineer's wrenches, it makes a specialty of making forgings from blue prints or samples, for anyone desiring this class of work. Parties interested or wishing to have forgings made will make their requests known direct to the factory at Brightwood, Mass.

LINK-BELT SPROCKET WHEELS.—The Link-Belt Engineering Company, Nicetown, Philadelphia, has just issued a circular devoted to link-belt case-hardened sprocket wheels. By the company's new process of case-hardening it is stated that the teeth and rims of the wheels are made so hard as to be practically indestructible, at the same time giving them a smooth, uniform and close-grained surface. These wheels are of advantage in all link-belt gearing, but are particularly recommended for use in cement mills, phosphate plants, stone crushing plants and for all work where grit is present. The circular has an illustration showing the depth of chill produced by the case hardening process.

NAVY VENTILATION.—In no branch of government service has the matter of ventilation been given such serious consideration as in the navy. The construction of the modern vessel renders it extremely difficult to secure proper ventilation in some portions below the water line. Noticeable for its novelty, among the various methods used to properly ventilate such places, is the portable ventilating set, consisting of a small exhauster of the "Monogram" type directly connected to an enclosed electric motor. It is very light, moves a large body of air, and is provided with handles for carrying from place to place, enabling the crew to work in any portion of the vessel with comfort, and is but one of the many types of blowers manufactured by the B. F. Sturtevant Company, of Boston, Mass.

INDUSTRIAL RAILWAYS.—In the modern industrial railway equipment where turn-tables are used for out-door work there is always a temptation to set the turn-tables upon too shallow a foundation, the result being that they are thrown out of line by the influence of the frost. In the new plant of the B. F. Sturtevant Company, at Hyde Park, Mass., where special turn-tables of its own manufacture have been very successfully introduced in connection with its industrial system, each turn-table rests at the top of a brick circular well with 8-inch walls extending to a depth of 4 ft. or below the frost line. These walls are set upon hard-pan and the center filled with loose stones providing perfect drainage. The first winter's experience has shown them to be absolutely uninjured by frost.

"IDEAL" ELECTRICAL MACHINERY.—The Ideal Electric & Mfg. Company, of Mansfield, Ohio, has recently placed on the market a complete line of "Ideal" electrical machinery embracing a line of elevator and hoist motors and controllers, a line of universal motors, and a complete line of belted and engine-type dynamos and generators in sizes up to 150 horse power. This company, while apparently new in the field, is backed by men of long years of experience in the design and manufacture of electrical machinery. In its shops at Mansfield it is using individual motor drive applied to the most modern machine tool equipment, and already the demand for its machines has forced the necessity for increased facilities, and a large new brick building with three floors is under way and will be ready for occupancy early in the spring. It is the intention of the company to work into larger units as soon as the proper facilities can be provided.

MILLING MACHINES.—The Hess Machine Company, 15th and Chestnut Streets, Philadelphia, Pa., has just brought an attractive pamphlet on the subject of milling machines and milling cutters for large output. The company guarantees feeds per minute of 10 inches or more in roughing off cast iron the full width of the machine, and on steel forgings and steel castings, four inches or more. The cutters are made on a new principle and do not "hog in" when changing from wide to narrow surfaces at full rates of speed. The machines are designed for direct electric driving by direct and alternating current motors. The pamphlet contains several excellent illustrations of milling machines of different sizes, each being accompanied by a table giving all the principal dimensions, speeds, etc. There is also a telegraph code, a chapter on the Hess Company's cutters for fast feeding closes the pamphlet. All machinists will be interested in this machine as it is evidently a great time and money saver.

ELECTRIC CONTROLLERS.—J. L. Schureman & Co., of Chicago, have issued two handsome pamphlets, Bulletins Nos. 19 and 20, describing respectively their line of electric elevator controllers and self starters and pressure regulators for direct current motors. These contain descriptions, dimension tables and price lists of the apparatus manufactured by the company, which makes a specialty of controllers of various kinds. It will be recalled that the business was formerly conducted under the name of Schureman & Hayen, the partnership having been dissolved July 1, 1903. Subsequently the company's business in electrical machinery was disposed of to the Gregory Electric Company, since which time Schureman & Company have been devoting themselves to the manufacture of controllers exclusively. Although these have been placed on the market for a number of years, no effort has been made in the past to push the line, but an aggressive policy is now being pursued.

FRINK LIGHTING.—In the perfecting of modern buildings, many problems have been solved by the Frink system of lighting, well known in lighting churches and public buildings. Some of the recent installations furnish further proof of its efficiency: Madison Ave. Baptist Church, Church of St. Edward the Martyr, Rutgers Presby. Church, Church of the Incarnation, Church of the Covenant, New York City. Immanuel Bapt. Church, Albany, N. Y. Westminster Presby. Church, Yonkers, N. Y. Church of St. Peter of Alcantara, Port Washington, L. I. First Presby. Church, Wheeling, W. Va., M. E. Church, Morristown, N. J. The New Amsterdam Theatre, probably the handsomest in New York, offers an excellent example of illumination by lights concealed in Frink cove reflectors. The effect is especially fine in the foyer, the fullest appreciation of the decoration of which is made possible only through the skillful handling of the lighting. Progressive merchants everywhere evidence their desire to share the benefits of Frink reflectors by equipping their windows with Frink special patent window reflector; show cases with reflectors especially designed for them and store interiors with special cluster reflectors which are economical and of highest efficiency. Full information concerning any of the above lines may be had by addressing the inventor, patentee and sole manufacturer, I. P. Frink, No. 551 Pearl St., New York City.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED DECEMBER 22, 1903.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., N. Y.]

747,345. SIGNALING APPARATUS; James E. Allison, St. Louis, Mo. App. filed Aug. 30, 1902. Details of a system wherein trains can signal the station agent.

747,354. ELECTRIC WELDING MACHINE; George Baehr, McKeesport, Pa. App. filed Aug. 6, 1902. A machine for electrically welding tubes in continuous lengths.

747,367. FLEXIBLE METALLIC TUBING FOR ARMORING INSULATED ELECTRICAL CONDUCTORS; Wm. H. K. Bowley, London, Eng. App. filed Nov. 17, 1902. A corrugated strip of metal coiled so that each turn is partially overlapped by the next succeeding turn, a strip of metal being wound in the spaces between the corrugations.

747,371. TROLLEY WHEEL; Herbert W. Brockett, Hamden, Conn. App. filed June 23, 1903. Two disks flank the wheel and being of greater diameter than the latter, tend to retain the wheel on the wire.

747,394. TELEPHONE WALL SET; Ernest B. Fahnstock, New York, N. Y. App. filed April 13, 1903.

747,421. MULTIPLE SWITCHBOARD; Carl M. Hedman, Chicago, Ill. App. filed May 22, 1902.

747,446. ELECTRIC LIGHTING ATTACHMENT FOR GAS STOVES; Samuel Lewellen, Philadelphia, Pa. App. filed Dec. 9, 1902. Sparking electrodes are moved at the same time the valve is turned.

747,454. ELECTRIC CONDUCTOR; Victor Lowendahl, Stockholm, Sweden. App. filed Feb. 7, 1903. Masses of granular carbon covered with metal are compressed into blocks to form a carbon brush.

747,470. SUPPORT FOR ELECTRICAL CONDUCTORS; Robert Orr and John Morrison, New York, N. Y. App. filed Jan. 9, 1903. A trolley clip consisting of two connected members each being provided with a wedge-shaped groove, a wedge-shaped wire-gripping clip being secured in the groove.

747,477. RAIL INSULATOR; Leonard M. Randolph, Newark, N. J. App. filed May 4, 1903. A non-porous insulating covering for ground rails, consisting of varnish residue and an absorbent substance pressed into intimate contact with the rail.

747,491. TELEPHONY; Harry O. Rugh, Chicago, Ill. App. filed June 2, 1902.

747,508. REGULATING DEVICE FOR ELECTRIC ARC LAMPS; Aron N. Thorin, Stockholm, Sweden. App. filed Aug. 2, 1902. A roller in contact with the carbon has its axle resting freely against an inclined frame and a spring dog engages the roller in such a manner that it is permitted to move down the incline with the carbon rod at each feeding operation and to finally grip the rod.

747,515. TELEPHONE OR LIKE CABLE; Francis Tremain, Highgate, Eng. App. filed Nov. 1, 1901.

747,528. FUSE AND FUSE-MAGAZINE; William P. Woodruff, Buffalo, N. Y. App. filed June 12, 1903.

747,537. ELECTRICAL SWITCH; George J. Crossland, Mobile, Ala. App. filed July 12, 1902. Details of a circuit closer for operating an electromagnetic railway switch.

747,553. CONNECTOR FOR ELECTRIC CIRCUITS; Wm. H. Kelsey, Cambridge, Mass. App. filed Sept. 24, 1902. A plug having two different styles of contact is arranged to be reversible upon a holder so that either set of contacts can be used.

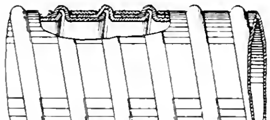
747,571. WINDING DEVICE FOR CABLES TO WHICH MOVABLE ELECTRIC APPARATUS IS ATTACHED; Gregor Ackermann, Biel, and Gustav Engisch, Madretsch, Switzerland. App. filed Nov. 5, 1902. Details of a spring drum arrangement for winding up a flexible cord.

747,595. COIL FOR ELECTRICAL MACHINES; Isaac De Kaiser, Pittsburg, Pa. App. filed May 1, 1903. The coil comprises an inner and an outer concentric portion, wound in opposite directions and having leads projecting from adjacent turns of the outer portion.

747,602. BATTERY TRANSMITTER; John S. Goldberg, Chicago, Ill. App. filed Nov. 17, 1902.

747,607. TROLLEY POLE; Jonah R. Hollis, Brockton, Mass. App. filed Nov. 7, 1902. The trolley harp is pivoted to permit the wheel to swing laterally.

747,609. ROSETTE; Edward J. Hunt, Toledo, Ohio. App. filed June 3, 1903. Details.



747,367.—Flexible Metallic Tubing for Armoring Insulated Electrical Conductors.

747,631. FIELD MAGNET COIL FOR ELECTRICAL MACHINES; Loyall A. Osborne, Pittsburg, Pa. App. filed June 24, 1903. The coil is formed of scrap copper and sheets of heat-resisting insulation between adjacent turns, the structure being inclosed in a hermetically shell.

747,673. ELECTRIC SWITCH; Charles C. Badeau, Swissvale, Pa. App. filed Aug. 12, 1903. Details of an overload switch.

747,686. SYSTEM OF ELECTRICAL REGULATION; John L. Creveling, New York, N. Y. App. filed Feb. 12, 1902. In a train lighting system where the generator is driven from the axle and supplies an accumulator, the generator is controlled automatically by the voltage of the accumulator.

747,696. BRUSH HOLDER; Henry Geisenhoner, Schenectady, N. Y. App. filed Dec. 17, 1900. The springs are mounted in hinged frames so that they can be tilted to one side when the brushes are to be removed.

747,697. ELECTRIC FUSE; Henry Geisenhoner, Schenectady, N. Y. App. filed May 31, 1901. The fusible strip is threaded back and forth through transverse openings in the cartridge, to prevent the formation of an arc.

747,698. DYNAMO ELECTRIC MACHINE; Henry Geisenhoner, Schenectady, N. Y. App. filed Aug. 28, 1901. The space between the teeth of the core is closed by a wooden wedge faced off with cement.

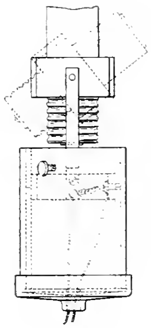
747,706. MAGNETIC CLUTCH; Edward M. Hewlett, Schenectady, N. Y. App. filed June 18, 1902. A stationary member contains the coil and attracts towards its opposite sides two rotary members.

747,707. ELEVATOR; Nelson Hiss, New York, and Harold S. Macaye, Yonkers, N. Y. App. filed May 31, 1902. Means whereby the car may be brought gradually and easily to rest at either end of its normal travel independently of the use of the ordinary controlling handle.

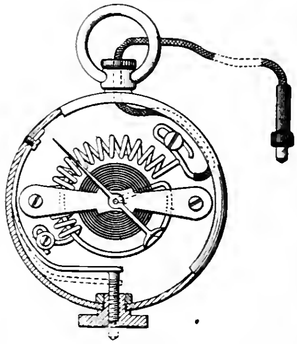
747,755. SPARK OIL; Charles P. L. Noxon, Syracuse, N. Y. App. filed Aug. 20, 1902. The face of the armature of the vibrator is grooved for the purpose of emphasizing the attractive force of the core.

747,763. REGISTERING MECHANISM; William H. Pratt, Lynn, Mass. App. filed Sept. 24, 1901. The combination with an integrating meter of means for registering thereby any excess of the quantity measured over a certain predetermined amount.

747,765. RAILWAY MOTOR; Edward D. Priest, Schenectady, N. Y. App. filed Sept. 16, 1902. Structural details relating to the split motor frame whereby the advantages of a box frame are also obtained.



747,553.—Connector for Electric Circuits.



747,871.—Measuring Instrument.

747,778. EXPRESS OR OTHER ANNUNCIATOR; Joseph H. Rusby, Nutley, N. J. App. filed Nov. 15, 1902. An electric sign containing the names of express companies with suitable switching apparatus for displaying any of them.

747,795. AUTOMATIC APPARATUS FOR CONTROLLING AND OPERATING THE POINTS OF ELECTRIC RAILWAYS OR TRAMWAYS; Thomas B. Stewart, Wm. H. Turner and Rowland E. Dixon, Leeds, Eng. App. filed April 1, 1902. Details.

747,796. APPARATUS FOR CONTROLLING AND OPERATING THE POINTS OF ELECTRIC RAILWAYS OR TRAMWAYS; Thomas B. Stewart, Wm. H. Turner and Rowland E. Dixon, Leeds, Eng. App. filed March 6, 1903. Details.

747,821. STARTING RHEOSTAT; Howard B. Wilson, Schenectady, N. Y. App. filed Aug. 21, 1902. The contact carried by the arm or a rheostat is in two parts, one being of higher resistance than the other, thus dividing the total current into two parts with a resulting diminution of sparking.

747,841. ELECTRIC APPARATUS FOR WELDING TUBES; George Baehr, McKeesport, Pa. App. filed Jan. 31, 1902. A machine in which flat plates are progressively bent into tubular form and the joint electrically welded, with adjustments for different sizes of tube.

747,842. ELECTRIC APPARATUS FOR WELDING TUBES; George Baehr, McKeesport, Pa. App. filed Jan. 31, 1902. The electric heating and welding apparatus is self-propelling along the tube blank to progressively heat and weld together the abutting edges of the blank.

747,847. STREET RAILWAY SWITCHING MECHANISM; Walter J. Bell, Los Angeles, Cal. App. filed May 7, 1903. Hydraulic pistons for moving the switch are locked and released by an electro-magnetic latch.

747,853. RETARDING DEVICE FOR ELECTRIC CIRCUIT BREAKERS; Algernon R. Cheyney, Philadelphia, Pa. App. filed April 16, 1903. A circulatory system for liquid is combined with a solenoid to get proper retardation of the core.

747,871. ELECTRICAL MEASURING INSTRUMENT; Earl C. Eldredge, Springfield, Mass. App. filed Oct. 3, 1903. A pocket volt-meter in which one of the contacts is at the end of a flexible cord, while the other is housed within the case, but can be readily extended when needed.

747,873. COMMUTATOR; Hermann F. T. Erben, Schenectady, N. Y. App. filed Aug. 10, 1901. Structural details.

747,876. INSULATING WIRE; Henry W. Fisher, Pittsburg, Pa. App. filed Nov. 1, 1902.

747,889. ELECTRIC LIGHTING SYSTEM; James F. McElroy, Albany, N. Y. App. filed Oct. 21, 1902. The regulator is controlled by a series of adjusting magnets included in separate lamp circuits, a storage battery being in multiple with the lamps and the dynamo being driven from a car axle.

747,890. BRUSH HOLDER FOR ELECTRICAL MACHINES; James E. McElroy, Albany, N. Y. App. filed March 5, 1903. A construction permitting the spring pressure to be relieved before reversing the holder or follower from its working position.

747,891. IMPLEMENT FOR FILLING WOOD SURFACES; Lewis W. Nelson, Grand Rapids, Mich. App. filed April 9, 1903. An electric heater applied to a heating iron.

747,911. CONNECTION TERMINAL AND PLUG; William W. Dean, Chicago, Ill. App. filed Dec. 26, 1900.

12,185. CONNECTION COUNTER FOR TELEPHONE LINES; Frank R. McBerty, Evanston, Ill. App. filed Jan. 16, 1900.

Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

CONTENTS.

THE IROQUOIS THEATRE FIRE.

Last week at the new Iroquois Theatre in Chicago some six hundred lives were lost through what would appear to be criminal carelessness and negligence on the part of those entrusted with the management of that place. The fire which broke out on the stage in the middle of an afternoon performance and swept suddenly through the house, is now under investigation, and we must await the results before attempting to distribute blame. On the face of it, however, there are many obvious points that deserve comment. One of these touches the wild recklessness with which electric lights appear to have been used around the stage. It has been alleged and has not so far been contradicted that one of the pieces of scenery was set on fire on account of the close proximity of a sputtering, unshielded arc lamp which was used for scenic purposes, while it is also stated that an incandescent lamp projector hindered the asbestos curtain from falling its full length to the floor of the stage. We trust these points will be fully cleared up. There is no medium so safe and convenient as electricity for light and power, especially around the stage, yet there is none which is so abused and trifled with. One result of the awful disaster in Chicago has been to close up half the places of amusement as unsafe, and we are heartily glad of it. In spite of all that is said to the contrary, just as sweeping an edict ought to be and could be put in force in New York City. Meantime it is a matter of congratulation that the authorities have ordered an examination of all the electric lighting appliances and facilities in the New York theatres. We trust that the examination will be as rigid and severe as the highest standards of the art can make it, and there is no reason why this inquisition should be limited to New York City.

GAS IN SECOND PLACE.

The public is accustomed to think of gas as still the leading illuminant, but while this is probably true in Europe, in the United States the sceptre of light has definitely passed to electricity. The figures just issued by our Census Office are, indeed, startling. Gas had nearly 75 years' start over its competitor, but it now appears to be decidedly in second place. Yet there is no denying the fact that the introduction of the brilliant electric light has stimulated greatly the use of gas. There are now close upon 4,000 electric light central stations in America, but by the census of 1900 there were then only 877 gas plants, and the number was not growing perceptibly. The gas plants were earning an income of $75,000,000. Last year the central stations earned $85,000,000. The cost of construction and equipment of both was over $500,000,000. Gas employed 22,400 men and electric light 23,300.

But this is only half the story. It is estimated that there are over 50,000 isolated electric light plants in this country, and that they represent as many lamps as do the central stations. New York City has 1,000 of them, and some, like that in the Waldorf-Astoria, would run many an ambitious Western city. Hence, the figures against gas are doubled in most respects. The 20,000,000 incandescent lamps burning nightly become 40,000,000. The 400,000 arc lamps—Shelley's "insistent sisters of the day"—become 800,000. Were it not for the universal use of the gas stove and the prevalence of the gas engine, one marvels what would have become of the illuminant of our fathers.

Such is the pace at which we live to-day that, while millions of people in this country have not yet got up to the stage of "civilization" represented by the use of gas, but when they encounter it casually employ it suicidally, other millions have outgrown and discarded it, and will have none of it even for a curling iron or a chafing dish, let alone for lighting. To put it briefly, the use of electricity for lighting in New York State alone has increased over 2,000 per cent. in ten years, and the use of electricity for power, also from central stations, has increased in the decade nearly 1,200 per cent. And yet the electricians are inclined to think they have only just started in.

Alternating Current Locomotives.

Through what might seem a curious chance, during the past few months several important papers have been read by American electrical engineers before the Canadian Society of Civil Engineers. Why such a body should have been chosen instead of the American Institute of Electrical Engineers as a medium of communication with the electrical engineering profession it is difficult to fathom, particularly since in two instances the communications were the first announcements of radical departures in engineering policy on the part of American electrical manufacturing companies. This recalls a similar instance of some months ago, when one of the most important engineering announcements of several years formed the subject of a paper read before a learned body more interested in a happening of the paleozoic age or a new nebular hypothesis than in such a utilitarian matter as a modern engineering advance like the the steam turbine. Can it be that, for some occult reason, the practice of theatre folks in avoiding urban publicity upon the trial performance of a play is extending to the technical field? A reprint of one of these Canadian papers, read November 19, has just come to hand, the subject being "Some Possibilities of the Alternating-Current, Single-Phase Railway Motor," and the author, Mr. A. H. Armstrong. In the opening paragraphs of his paper Mr. Armstrong pronounces strongly in favor of the new departure in electric traction indicated by the development recently of single-phase alternating-current motors, which he says have a speed torque characteristic even better adapted for railway work than that of the direct-current series motor and, furthermore, providing ample starting torque with any voltage variation liable to occur in practical railway operation. He adds that as these motors can be operated with the single trolley and ground return and, moreover, can be operated satisfactorily on either direct or alternating current, their field of usefulness is much greater than that of their direct-current series motor competitor. He considers that this type of motor enables us to break away from the exclusive field of electric traction with frequent service and small units, and to render possible the operation of freight and passenger trains over regular steam lines.

The paper proceeds to make a comparison in detail between steam and alternating-current locomotive traction with reference to train weights of 250, 500, 1,000 and 2,000 tons, at speeds up to a maximum of 60 to 70 miles an hour. All of the steam data are based as far as possible upon actual locomotive performance sheets; the electrical data relating to the generating station are derived from present generating station practice, which, it is stated, would be merely duplicated in railway practice. The standard electrical apparatus and voltages met with in present everyday practice are only considered, and the results thus do not represent what electrical engineers may confidently expect to be able to do some time even in the near future. The conclusions are that for very infrequent service—that is, five trains per day each way or less—it would hardly pay to equip present steam roads electrically. With more frequent service, however, the saving in electrical operation becomes more marked until at from 15 to 20 trains per day each way the interest earning power of the electrical investment becomes significant. Taking into account, however, that the electrically-equipped road while carrying heavy through freight traffic with an earning capacity of from 4 to 7 per cent. on the investment, can also build up a local traffic, both freight and passenger, with practically no additional cost and showing very large returns, the balance is still more in favor of the electric locomotive. After discussing incidental savings which may be made with the electric system, and which were not taken into consideration in the preceding calculations, the final conclusion of the author is that should all the factors entering into the engineering expense of operating roads by steam and by electric locomotives be carefully considered, the possibilities opened up by the use of alternating-current motors are sufficiently great to warrant its replacing the steam locomotive in many of our railway systems, either in part or for the complete system. As this opinion may be taken to reflect the present policy of one of the great electrical manufacturing companies, which company until quite recently was—if we are to judge by the attitude of members of its technical staff in discussions on the subject—committed against alternating-current traction, the revolutionary change that in the past few months has taken place with respect to the electric traction situation is sharply defined.

Measurement of Current by Copper Coulombmeter.

A matter of considerable interest is the relative value of the two fundamental methods now in use for calibrating standard voltmeters and ammeters. The first method is to use a voltameter, which, by the way, is an unfortunate term, since it resembles "voltmeter" so closely, and the term coulombmeter has consequently been wisely suggested as a convenient substitute. The second method is to use a standard cell. The first method involves the measurement of electric quantity, and thence, with the aid of elapsed time, the mean electric current strength. This measured current strength will serve to calibrate a standard ammeter directly, and will also serve to calibrate a standard voltmeter indirectly, by passing the measured current through a coil of known resistance. The second method involves the comparison of a convenient uniform e.m.f. with the e.m.f. of a Clark cell, through the medium of a potentiometer or equivalent device. In this manner a standard voltmeter may be calibrated directly, while a standard ammeter may be calibrated indirectly, by passing a current from the measured e.m.f. through the ammeter and a standard coil of known resistance.

For the purposes of commercial accuracy, either of these two methods is available. So soon, however, as the highest laboratory standard of accuracy is desired, difference of opinion is encountered as to the relative advantages of the two methods. There are potentiometer advocates, and there are coulombmeter advocates. It is interesting to observe that both methods are similar, in being fundamentally electrolytic. One, however, employs the electrolytic plating bath, while the other employs the electrolytic cell or couple. The theoretical value of the silver or copper coulombmeter method is in the Faraday law which declares that a definite quantity of metal must be removed from the anode and deposited on the cathode, for every unit quantity of electricity passing through the plating bath. The theoretical claim of the potentiometer method is that with the commercialy attainable degree to chemical purity in the substances employed, Clark cells can be reduplicated to a very satisfactory degree of accuracy in e.m.f.

The disadvantage, or weak point of the coulombmeter method is that although in strict theory the anode loses as much metal as the cathode gains, yet in practice there is always an appreciable difference between the loss of the anode and the gain of the cathode. This difference is apparently attributable to secondary chemical actions at the anode and cathode surfaces; but whatever the explanation may be, the discrepancy introduces a certain small element of uncertainty, and it is generally admitted that the same quantity of electricity in coulombs will not produce exactly the same apparent transfer of metal when the quantity is transferred during an hour, as when transferred during a week. The disadvantage or weak point of the potentiometer method is that it is less direct than the coulombmeter method, since the coulombmeter, with a stop-watch and a chemical balance, can give a result that immediately yields the value of a certain reading on an ammeter scale; whereas the potentiometer method involves not only the error of the Clark cell, but also the error of the potentiometer. Moreover, Clark cells may not agree very closely, unless the method of setting them up be uniform, even when pure chemicals are employed; since if the mercurious sulphate solution is saturated or unsaturated makes an appreciable difference in the value of the e.m.f. at a given temperature, as well as in the temperature coefficient of variation in e.m.f.

We are inclined to the belief that if Clark cells or cadmium cells are made up according to uniform and standard specifications, their e.m.f. can be depended upon to within a very small range of variation or error, say 1/30 of one per cent., and that the error of potentiometer comparison can, with sufficient care, be made negligibly small. Consequently, standard voltmeter calibrations by the potentiometer method may be carried with reasonable care to about 1/13 of one per cent. On the other hand, differences in the making up of Clark cells may involve variations in voltmeter calibration of as much as ⅙ of one per cent. in practice. This is about as great a variation as may be found in coulombmeter measurements. Consequently, one method is about as good as the other if no special precautions are taken in regard to the standard cell. If, however, the Clark or cadmium cell can be brought by suitable international specifications to the smallest range of variation of which it is reasonably capable, then we think the potentiometer method will be found superior. At the present time many of our standard instruments in laboratory use are calibrated by the coulombmeter, and many are also calibrated by potentiometer. In many practical cases the limits of desired accuracy are such that either method is equally suitable regardless of the absolute superiority of one or the other.

THE PROGRESS OF ELECTROTECHNICAL EDUCATION.

The condition of electrotechnical education in the United States at the present time is very satisfactory. The ideal condition of technical education is that it should be open to all comers and to every citizen. It should not be stereotyped and forced into any one or two sharply defined forms, but should be multiplied and varied in degree, in time, in expectation and in cost, so that all localities, pursuits, qualifications and purses may be suited. There is no royal road to learning, and there should be built no artificial causeway. The sole conditions on which knowledge and proficiency of any kind are to be had are attention and time; or what is equivalent, effort and perseverence. These will win everywhere, and at all times, so that it is only of importance to throw facility into the line of endeavor. To the artisan belongs the night school, since his daily work forbids him to give attention except at night. The manual training school is open to the young mechanic, with limited means and time for education. The correspondence school is specially adapted to those who, remote from cities, or occupied during educational hours, can devote time to what the teacher and the mail-carrier may provide. All these do very important work for the many. To the favored few are open the higher branches of technical education offered by technical colleges. These are most costly both in time and in money. They represent an investment made by the student in education as vested capital, upon which interest returns are demanded throughout subsequent working life.

No education can expect to flourish in this age, which does not pay as well as interest. We all desire the purely ornamental, but we want only such an amount as shall adorn the stern creations of necessity and use. A few grammes of gold will gild a large mass of less valuable structural material. On the other hand, the education should not only be graded to the student, but the student to the education. The college training may be thrown away upon a student who does not possess technological aptitude. An engineer must be born as well as made. No amount of education can make up for inherent defects in vitality, temperament or specialized mental capacity. There are some students who will learn much in a manual training school and but little from a technical college. The main effort should be to increase each individual's usefulness to the utmost that local conditions will permit. Work and acquisition of some kind should be the rule for all, and the most work, the highest kind of teaching, for the few who can afford and can avail themselves of the greatest development.

In the development of our industrial resources the time has gone by when lesser proficiency will meet requirements. At this time each factory and workshop is virtually in competition with the rest of the world, and only the fitted can survive. Consequently, while empirical methods and the guidance of experience were adequate to technical prominence only a few decades ago, now they are insufficient, and the best scientific equipment must be added to experience in order successfully to cope with the engineering problems of the day. For this reason we see the technical college graduate of the best ability and best training assuming the positions of responsibility, not only in the productive and constructive departments of modern industry, but also beginning to dominate in the administrative and commercial branches. The very best material, brains and training are only just good enough for the purpose of the day. They would be relegated to a second place if yet better vitality, brains, knowledge, training and experience could be obtained. Every year must see more demand for highly specialized students of the best technical training, and the best positions will naturally tend to the possession of those who, other things being equal, have had the best education and training.

At the same time it must be remembered that the great bulk of the people employed in electrotechnical industry, the rank and file of those who produce and who apply, must continue to receive their training, so far as it can be provided outside of the school of practical experience, in the night school, or high school, or correspondence school. In the nature of things many men will attain technical prominence who have never enjoyed the advantages of special training, laboratory teaching, or technical colleges. Such men advance by right and reason of special born abilities. But because one man in the million is a genius as a painter, and becomes eminent as an untaught artist, is no reason why painting should not be regularly taught in special schools, but rather the reverse. The numerous and varied facilities for acquiring technological education in America at this time, as well as the evident endeavor of all classes to improve their education throughout life, is the most encouraging symptom, and progressive evidence of, Western civilization.

The Joint Engineering Building Plan.

With regard to the work of the committee of fifteen on the joint Engineering Building given by Mr. Carnegie at a cost of $1,000,000 and upwards, the American Society of Mechanical Engineers has just issued a most interesting circular on the subject embodying a good deal of new material and data. The chief item is the report of the committee on organization, composed of Dr. A. R. Ledoux, C. W. Hunt and Dr. S. S. Wheeler. We give it below:

Having considered legal advice and taken note of all suggestions received, the committee unanimously advise as follows:

1. The total amount offered by Mr. Carnegie shall be administered as two gifts: one to the Engineering Societies and the other to the Engineers' Club, each to be held and administered independent of the other. The allocation of the fund to be made at once, but the buildings to be designed and erected as one operation: thereafter the respective titles and administrations to be entirely independent.

2. The property represented by land, buildings and equipment of the engineering societies, shall be held and administered by an executive corporate body, preferably under a special charter, to be obtained from the State of New York, each of the constituent societies being entitled to name from its membership three persons to act as incorporators and thereafter as directors.

3. Each society annually to elect or appoint, as their by-laws may prescribe, one of their voting members to serve on the Board of Directors of the Executive Corporation for a term of three years; a vacancy in said board to be filled by an appointment made by the society the retirement of whose representative causes the vacancy.

4. The land and property being held for the societies by an Executive Corporation, the said corporation may, to pay for the land acquired, issue certificates of indebtedness or bonds bearing interest at four per cent., and redeemable on six months' notice, the buildings being a gift from Mr. Carnegie.

5. Each of the constituent societies may purchase and hold an equal amount in value of the said bonds or certificates, but the Board of Directors of the Executive Corporation may authorize any of the constituent societies to hold an additional amount; that is, in excess of its portion, but such excess shall be subject to recall at its par value at any time that the directors of the Executive Corporation may so order, to the end that each society shall have an equal interest in the property of the corporation if it so desires.

The certificates held by each society shall be inalienable unless they are offered to the Executive Corporation at their par value, and such tender shall not be accepted by the Board of Directors within one year thereafter.

6. The property of the Executive Corporation shall be used perpetually as a meeting place and headquarters for the constituent societies, and for such other scientific associations as may be temporarily admitted by the consent of the Board of Directors of the Executive Corporation. Such associations may pay a pro rata share in the expenses of the headquarters, but no profit shall be made from such use.

7. Each of the participating societies shall be entitled to rooms and space in the property adequate to its need, paying its share of the running expenses in accordance with the amount of space occupied; said space to be assigned and a proper assessment therefor determined by the Board of Directors of the Executive Corporation.

8. The excess of receipts over expenditures, if any, shall be used for reducing the subsequent contribution of the several societies for maintaining the building, and for the advancing of engineering arts and science, by and through the participating constituent associations. No dividends shall be declared or profits divided, but a reasonable repair and rebuilding fund may be established.

9. If the income of the Executive Corporation shall be less than the expenditure, the deficiency shall be made good by an assessment on each of the constituent societies, so allocated as to be in proportion to the number of voting members of each society.

An excess of receipts over expenditures may be allocated to the societies in like manner to reduce their annual assessment.

10. Should any of the constituent societies fail or refuse to appoint directors, the remaining members of the board of the Executive Corporation shall administer the property with all the force and effect as though the board contained its full quota of members.

11. Finally your committee, in offering the above suggestions, has had in mind the setting aside of the money used for a building for the Engineers' Club, so that on the completion of the said building the relations of the club and of the engineering societies will terminate. Thenceforward, the constituent societies are to carry through the Executive Corporation the administration of the building and its accessories, leaving the scientific, professional, intellectual and financial activity in each organization entirely independent of the others, and free to develop to any extent and along any line that may be determined each for itself.

The details of the superintendence and administration of the buildings can best be considered after the organization of the proposed Executive Corporation through the procuring of a special charter. As to the above report we may add that the ideas and plans that are being developed involve two separate buildings, even without physical union or means of common access, one for the engineering societies and the other for the Engineers' Club. No objections are raised to this in any respect.

An Edison Medal for the Institute.

In order to celebrate the twenty-fifth anniversary of the introduction and commercial development of the incandescent lamp, the friends and associates of Mr. Thomas A. Edison have taken steps to found a medal which will be entrusted to the American Institute of Electrical Engineers, and which it is proposed to award annually to graduating students in electrical engineering. The Institute, through its council, has already accepted the trusteeship of this fund and the circular which is being issued by the Edison Medal Association announces that it is the intention that the medal shall be awarded each year to the graduating student who shall present the best thesis on some original subject, from the universities and colleges of the United States and Canada which have regular courses in electrical engineering. It will be remembered that Mr. Edison's mother was a Canadian; that part of his own active life has been spent in that country, and that to-day the Institute not only selects some of its officers from that country, but that professors and students are freely interchangeable; considerations which render the inclusion of Canada by the founders of the medal eminently appropriate. It is proposed that the medal shall be executed by some artist of distinction and that if possible a permanent fund of about $5,000 shall be established for its maintenance. To carry this purpose into effect an Edison Medal Association has been organized, and it is proposed to present the medal fund at the annual dinner of the Institute on February 11, at which Mr. Edison will be a guest of honor. It is Mr. Edison's birthday also. The dinner is to be held at the Waldorf-Astoria and there is already every indication that it will be one of the most memorable functions of the kind that the Institute has ever enjoyed. The Edison Medal Association has as its officers Mr. Samuel Insull, chairman; Mr. Charles Batchelor as vice-chairman; Mr. Frank S. Hastings as treasurer, and Mr. Robert Ten Eyck Lozier as secretary. These "old Edison men" are reinforced and assisted by an executive committee of some 30 others, all of whom have been intimately associated with Edison developments, and by a general committee of about 100, all of whom have also at some stage of their careers been more or less closely identified with Mr. Edison's work. The Edison Medal Association has also appointed a dinner committee to co-operate with the Institute dinner committee under Mr. Calvin W. Rice, and has appointed other committees on various branches of its work. The executive committee includes Willie S. Andrews, C. Batchelor, Sig. Bergmann, R. R. Bowker, C. A. Coffin, R. N. Dyer, S. B. Eaton, C. L. Edgar, W. E. Gilmore, W. J. Hammer, C. T. Hughes, F. S. Hastings, S. Insull, E. H. Johnson, F. Jehl, A. E. Kennelly, J. W. Lieb, Jr., H. W. Leonard, R. T. E. Lozier, E. H. Lewis, W. S. Mallory, J. P. Morgan, T C. Martin, J. Ott, J. P. Ord, E. Rathenau, P. Seubel, F. J. Sprague, F. Thurnauer, S. S. Wheeler and F. R. Upton.

A great deal of interest is taken in this movement throughout the Institute ranks and amongst the numerous old associates of Mr. Edison, not only because the first Institute medal will thus be founded, but because one of the great epochs in electrical development will be celebrated. The twenty-fifth anniversary of incandescent lighting is also to be recognized this year at the St. Louis Exposition by the Edison companies; but it has been felt that in its engineering aspects the occasion is one which could be fitly and legitimately used to identify the Institute with the lighting art, and by this representative affair enlarge the sphere of its influence and responsibilities, since the medal is to be put in its charge. The address of Treasurer Hastings is 80 Broadway, New York.

A Combined Steam and Water-Power Central Station at Richmond.

ABOUT five years ago the construction of a power station was begun at Richmond for the Virginia Electrical Railway & Development Company to furnish current as a competitor in the electric railway and the general electric power and lighting business of that city. Water rights along the river at that point had been secured and plans were drawn for a development of 10,000 hp. Owing to the necessity for a continuity of service and in view of the fact that this could not be secured from the river either at low water or in times of freshets, a steam plant was arranged for, equivalent in capacity to the water power. The initial plant, which was completed about two years ago, was only carried for an output of 4,000 hp, but in the meantime the property passed into the hands of the Virginia Passenger & Power Company, which now represents a consolidation of the railway and electric services of Richmond, and during the present year work has been in progress until the full 10,000 hp is now practically available.

Both the hydraulic and the steam ends of the plant are unusually interesting. The former comprehends a long, low dam, provided with flashboards of both the automatic and the non-automatic type, a necessarily small canal to conduct the water to the power house, the limited cross-section creating a comparatively high velocity of flow, and the usually submerged, low-head water wheels. The steam plant includes vertical steam engines of 1,000 hp each, appropriately styled as steeple engines. A specially instructive feature of the station lies in the relative locations of the water and steam machinery and the limitations of their separate or conjoined operation.

The water rights were formerly owned by a flouring mill on Johnson's Island. The design and construction of the hydraulic portion of the first completed part of the station, including the power house, was in charge of Mr. Reuben Shirreffs, M.A.Soc.C.E., as chief engineer, now chief engineer directing a water power development at Great Falls, near Washington. Mr. J. H. Apsey was superintendent for Messrs. Winston & Co., of Chicago, contractors on the dam, canal and power house foundations. The steam and electrical features were designed by Mr. E. J. Willis, M.Am.Inst.E.E., now president of the Richmond Electric Company, of Richmond, who was succeeded by Mr. J. P. Pope. Messrs. Sargent & Lundy, of Chicago, were consulting engineers on the steam plant. Since the consolidation of the local companies, in which Mr. Frank Jay Gould, of New York, has a controlling interest, Mr. William C. Whitner has been retained as chief engineer for the water power developments of the Virginia Passenger & Power Company, and under his supervision the power house has been extended, additional units installed, some changes made in the canal and intakes and a new type of dam designed for the portion of the original work that had not yet been completed when Mr. Whitner was appointed.

FIG. 1.—VIEW OF ENGINE ROOM.

The city of Richmond is situated at the head of tidewater about 100 miles from the mouth of the James River. In the last three miles above navigation the fall of the river is 84 ft. and within nine miles 112 ft. The watershed of the river is 6,900 sq. miles. Mr. Whitner states that the average rainfall is 42 in., and from records of the Geological Survey assumes that it is not advisable to figure that the minimum flow of the James River at Richmond exceeds 700 cu. ft. per second, or 0.1 ft. per square mile of the catchment basin. About 100 cu. ft. per second pass through the Chesapeake & Ohio Canal and are not available for power. In considering the obtainable power in the river, complication exists owing to the fact that diversion has to be made to the Manchester Canal, which supplies water for operating a number of mills located along its bank. This is the property of the company, but the contracts under which water is furnished could not, practically, be changed. It is estimated that 600 cu. ft. per second are disposed of in this way, under a fall of 19 ft. At periods of very low flow, however, the Manchester Canal tenants are only entitled to one-half the water in the river. The James River plant is designed for a head of 25 ft. and assuming a combined efficiency of the wheels and generators of 75 per cent., and allowing for the diversion to the Manchester Canal, the following schedule of power has been prepared by Mr. Whitner. For five months, 8,846 hp; for six months, 6,242 hp; for eight months, 4,012 hp; for nine months, 2,982 hp; for eleven and a half months, 1,065 hp; minimum, 639 hp. This summary shows the necessity, if it is desired to supply 10,000 hp continually from its plant, for the steam engine adjunct. It shows that if 9,000 hp is the demand, the engines would not have to be operated at all practically for five months; that for one month they would have to supply 2,758 hp; for two months they would have to supply 4,988 hp, and so on. For fifteen days they would have to meet practically the entire demand. Of course, it must be remembered that these results are based on the minimum flow, which is not necessarily an annual occurrence.

The dam extends straight across the river at the upper end of Brown's Island. The hand gate house, which controls the entrance of water to the power canal, is a continuation of the dam, extending from the island to the east bank, to a point on the property of the Tredegar Iron Works. In a contract with that company the level of the water in the pond above the dam was fixed at elevation 44.75, and the level of the water in the canal just below the gate house at elevation 43. The contract also stipulated that the elevation of the top of the dam should not exceed 40.5, but provides that movable crests or flashboards can be used, by which the level of the water in the pond can ordinarily be kept at elevation 44.75. It requires that these flashboards shall be lowered or raised in times of high water so as to maintain the water level as nearly at elevation 44.75 as possible. The canal leading to the power house is 2,200 ft. long and the power house, at the end, is located at the river side. The elevation of the tail water at the other side of the power house is ordinarily 17, so that the gross head is 26 ft.

The dam is a concrete masonry structure over 1,700 ft. long, inclusive of a guard wall at the upper end of the channel. The average height of the crest is only 5 ft. above the solid granite bed of the river, on which the dam is built. That a head of 26 or 27 ft. is realized with a dam of this height is indicative of the rapid drop in the river between the dam and the power house. The minimum height of dam is about 8 ft. A higher one would probably have been constructed, except for the reasons mentioned, and the probability that serious damage might come to property above the dam at times of extreme freshets. At intervals of 40 ft. concrete piers 4 ft. wide were built along the top of the dam, 10½ ft. above the crest of the dam, to support the structure for moving the flashboards. Their height was taken to bring them above the highest flood levels, and to them are hinged the timber gates or flashboards. When resting on the dam proper these maintain the desired level in the pond, as will be noted in detail below. The movable flashboards are constructed of heavy pine timber in planking and are faced with cotton duck heavily coated with North Carolina tar as a preventive of leakage.

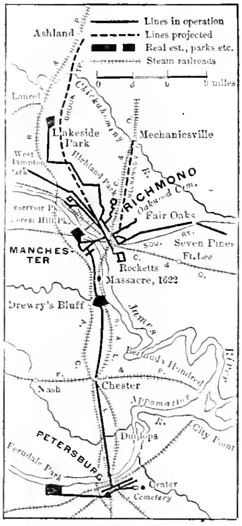

FIG. 2.—MAP OF RAILWAY SYSTEM.

The manipulation of these gates is one of the interesting features of the original design. Timber bridging spans the piers the length of the dam and this carries tracking on which is moved a hand car. The car carries a 3-hp electric motor for hauling up each gate, which is then fastened in its uppermost position, and the car is pushed from gate to gate for this purpose. There are 43 of the dropping crests, all told, each practically 36 ft. long, but the later ones are of an entirely different type. About 1,200 ft. of the dam were completed by the original company, leaving about 560 ft. to be built. This later work has been carried on by Mr. Whitner, who designed the movable crest, which is an interesting feature of the plant. This is designed to be automatic and consists, as shown, of a hinged apron inclined with the direction of flow so that there is a downward pressure on it, due to the presence of water above it. The hinge is at its lower edge, while the upper edge is hung from the end of levers, at the other ends of which is a counterbalance. When the level of the pond rises above the predetermined elevation of 44.51, the weight of the extra amount of water is designed to overbalance the counterweight, so that the apron will descend and lower the rollway crest. It will be noted that the shape of the concrete dam proper at the top is different from that for the old portion on account of the new type of flashboard. The apron consists of 6 x 10-in. pine timbers 9 ft. long, bolted together by iron plates at the bottom and top and strengthened at the top by a 15-in., 42-pound I-beam. There are two levers, one at each end, composed of 12-in., 31½-pound I-beams 15 ft. long, with two lever arms 4 and 10 ft. in length. The apron is suspended from each lever by a heavy chain. The counterweight is a cubical mass of concrete, measuring about 26 cu. ft.

A signal station is maintained at Columbia, Va., about 50 miles upstream, from which reports can be sent to Richmond by telephone of the water level at that point. By this means notices of floods are received twelve hours in advance of a rise at Richmond and men immediately start raising the gates in anticipation of the high water. Of course, with the automatic type of flashboard this is unnecessary.

The upper 900 ft. of the canal is a natural channel, enlarged by an excavation of earth and rock to an average waterway of 1,200 sq. ft. The lower end, or 1,600 ft., has concrete masonry side walls and a smooth lining of concrete on the bottom, the walls to retain the banks, as the width available was limited, and the bottom lining to increase the capacity to carry water, the lower part of the excavation being in solid rock. Its area is about 650 sq. ft. It was estimated that the canal would deliver to the station 5,500 to 6,000 cu. ft. per second with a loss of not more than 12 to 15 in. the whole length. The velocity under these conditions is about 9 ft. per second. To diminish the loss of head as far as possible, an unusual amount of gate area was provided at the head house. There are ten openings, each 12 ft. wide and 8 ft. high. The openings were fitted with heavy timber frames, each of which supports five smaller gates. This division was employed to regulate the supply of water when the river is high, but when the river is low the openings are left unobstructed.

The power house is located, as already stated, parallel to the axis of the canal, so that the forebay is comparatively small, at least where the water has to change its direction 90° before entering the wheel chambers. With the extension of the power house the end canal was enlarged as much as the width of the property would allow and the racks, which were formerly set across the canal, have been put immediately in front of the wheel chambers, increasing the area of flow through them, it is stated, three and one-half times. In connection with them an interesting device has been provided to clean the racks mechanically. The racks are composed of 3½ x ⅜-in. steel bars spaced on 1⅝-in. centers and each rack structure protects an opening 18 ft. wide. The cleaning device comprises a number of large combs, on which the projecting teeth fit in between the bars of the racks, and of endless chains on which the combs are fixed and by which they are moved upward along the rack bars. The comb consists of an angle bar with teeth of ½ x 1-in. iron, pointed, and riveted to the angle on 1⅝-in. centers. The chains are driven at the top by a motor connected to a shaft, which carries the necessary sprocket wheels.

The power house is built on bed rock, and, on account of the great weight of the machinery installed, on the one hand, and the considerable upward pressure of water in extreme freshets, which reach a level of 20 ft. above the boiler room floor, on the other, the foundations have been made unusually massive. The water wheels, which are of the horizontal type, are mounted in pairs, one pair submerged in each wheel chamber. The wheel chambers are arched overhead and support the boiler room for the steam plant. The tail water from the turbines reaches the tailrace through a comparatively long draft tube and across the draft tubes is located the generator room. The shaft from the water wheels extends into this and is directly attached to the generator, and on the other side of the generator is the steam engine, placed also in line for direct connection, when necessary. Under the engine room the entire space excavated is solidly filled with concrete, except for the draft tubes, which are circular in section, 10½ ft. in diameter at the outlet of the wheels, enlarging to 14 ft. at the river wall. The extensive use of concrete masonry is noticeable, as not only the dam, the canal masonry and power house foundations are constructed of it, but the walls and roof of the first portion of the station, the switchbard gallery floor and even the outer shell of the chimney are concrete. Portland cement was used for the most part, except in places where weight only was required, and there natural cement was used. It was stated that the stone from the excavations was unsuitable for stone masonry, and the use of concrete in constructing the building and chimney made architectural effects possible at a comparatively low cost. The foundation work was built in forms and the shaft of the chimney was constructed in the same way. The walls of the superstructure, however, were built of blocks of concrete, previously molded in boxes and laid up in the walls like stone ashlar. This part of the station was built large enough for four units of 1,000 hp each. The extension is designed for six additional 1,000-hp units, so that the capacity will be 10,000 hp.

Six pairs of the water wheels are of the Victor cylinder gate type, built by the Stilwell-Bierce & Smith-Vaile Company. Each is 51 in. in diameter and the pair guaranteed to develop 1,200 hp under a 25-ft. head. The seventh pair of wheels thus far installed consists of Hercules turbines built by the Holyoke Machine Company. The shaft from each pair extends in the usual way to the engine room through an opening in the partition wall. Each generator is a continuous-current machine of 700-kw capacity, built by the General Electric Company. The engines are steeple tandem-compound Allis engines. They are arranged to run condensing or non-condensing and are rated at 750 hp and at best economy are capable of delivering 1,500 hp. The water wheels are controlled by Lombard governors.

The steam engine cylinders are 18 and 36 in. in diameter with a 42-in. stroke, and they are equipped with the Reynolds valve gear and ball governors. A bolted flange coupling effects the connection between the turbines and the generators. The engine fly-wheel, which weighs 80,000 pounds, is mounted between the generator bearings and runs with the generator, whether driven by the turbine or engine. The engines are disconnected by uncoupling the connecting rods from the crank pins. To change from the water to the steam plant, bolts are removed from the couplings and the connecting rod is connected to the crank pin. To change from steam to water the operation is, of course, reversed. It is stated that the change requires about 45 minutes. The reason that the engines have a most economical rating at the comparatively low power is that this machinery is depended on to operate alone but for a small portion of the year. They are intended principally to supplement the wheels in time of low water and to maintain proper speed in the turbines at high water.

The condensing plant presents an interesting combination of two Worthington elevated injector condensers set at different levels. The lower one is operated normally under the head existing between the canal and the river. The second condenser is provided with an electrically-driven centrifugal pump, which has a capacity of 1,600 gallons per minute, to meet the conditions of high water when the natural head may prove insufficient. The condenser plant has a rated capacity of 6,000 hp. It is provided with a double-acting Worthington dry vacuum pump, 10 x 18 x 18 in. in size.

The boiler installation consists of four 1,000-hp batteries of Babcock & Wilcox water tube boilers, each having 252 tubes 4 in. in diameter and 18 ft. long, and three steam drums 3½ ft. in diameter and 20 ft. 4 in. long. They are rated at 500 hp each, on the basis of 10 sq. ft. of heating surface per horse-power and 0.2 sq. ft. of grate surface per horse-power, so that the ratio of grate area to heating surface is 1 to 50. The ultimate steam capacity of the plant is 4,000 hp.

It will be noted from the cross-section drawing of the station that coal is delivered in the railroad cars pushed on a trestle in the boiler room. The coal is readily dumped immediately in front of the boilers and there is storage capacity for about 120 tons. Semi-bituminous coal is used and as labor is cheap and the boilers are not operated continuously, they are hand-fired. The chimney is 11 ft. in diameter and 175 ft. high above the boiler grates. Feed water is drawn from the canal; but there is, also, a connection with the city mains, so that in times of excessive turbidity in the canal the boilers may be kept free from scale-forming water. There are two feed pumps of the Knowles duplex type, 6 x 10 x 12 in. in dimension. The water

FIG. 3.—EXTERIOR VIEW OF HYDRAULIC POWER HOUSE.

is discharged by the pumps through a Berryman feed water heater, 36 in. in diameter, provided with the usual by-passes for both the exhaust steam and the feed water. The only steam passing through the heater is that from the dry vacuum and the feed water.

The steam pressure is 150 pounds per sq. in., and extra heavy wrought-iron flanged pipe was installed for all the steam mains. The Chapman valves are employed, and the high-pressure mains and pipes are drained into the boilers by means of the Holly system. The steam header is 14 in. in diameter and the exhaust header 36 in.

In addition to the machinery described, there are two drainage pumps on the engine room floor with a combined capacity of 600 gallons per minute, furnished to handle any water which may percolate through the masonry during freshets. A 25-ton traveling crane built by the Whiting Foundry Equipment Company spans the engine room.

Being an independent company when the work was instituted, a variety of service was arranged for. The switchboards, which are situated on a gallery running around the engine room, are quite extensive. Direct current is supplied for railway work and for light and power, and for the latter there are two high and two low bus-bars and one common neutral bus on the lighting panels, the Edison system of distribution being employed. Alternating current is also furnished, and besides the generator and exciter panels, the switchboard has 10 railway feeder panels, 10 Edison panels and 2 alternating-current panels. The unusual feature is presented of a water power station situated almost at the center of its load, two-thirds of it being located within a radius of 1½ miles. On this account the three-wire system of distribution was adopted, 235 volts for light and 470 for power, reserving the alternating system for service out-

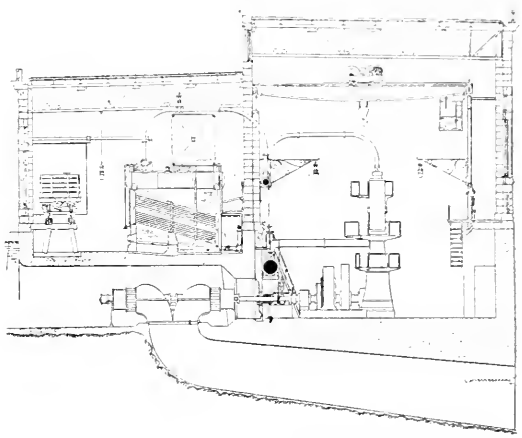

FIG. 4.—CROSS SECTION DIAGRAM OF POWER HOUSE.

side this zone. The voltage for this service is 2,300 at the station, with transformation to 115 volts, for local distribution. The railway current is, of course, delivered at 550 volts. The current is distributed both through underground conduits and overhead feeders. In the former the conductors are rubber-covered lead-enclosed feeders, furnished by the John A. Roebling's Sons Company. The electric controlling apparatus is of standard General Electric manufacture.

The officers of the Virginia Passenger & Power Company is as follows: President, Mr. F. Sitterding, of Richmond; first vice-president, Mr. Frank Jay Gould, of New York; second vice-president, Mr. Augustus Wright, of Petersburg; secretary and treasurer, Mr. Guy Phillips, of New York; assistant secretary and treasurer, Mr. William Northrop, of Richmond. The late construction work, except the extension to the power house, which was erected by Mr. John Mann, Jr., was done by the company's own forces.

A Long Trolley Line.

A telegram from Richmond, Ind., of January 1 says: "If the plans of the men who are the power behind the Columbus, Greensburg & Richmond Traction Company materialize the company will have one of the greatest systems of trolley lines in the world. The plans contemplate not only a line from Columbus through Greensburg to Richmond, but also several long branch lines. One is to run to Louisville. Another is to run into Cincinnati. At Greenfield connection will be made with the Indianapolis & Eastern for Indianapolis. The line to Richmond is not merely to run into this city, but is to extend through the city and east to Cleveland, with Buffalo as its ultimate terminal. This would give the company direct connections with Indianapolis, Louisville, Cincinnati, Cleveland and Buffalo. The third-rail system is to be used except inside the corporations, where it is necessary to resort to overhead construction. The company will make use of private right of way."

The Government Printing Office—The Electrical Equipment of the Largest Printing Office in the World.—II.

DISTRIBUTION, ETC.

IN the first part of this article it was attempted to give an account of the Government Printing Office at Washington, as the largest printing office in the world, and that in which the application of electricity to the various processes of typography finds its most notable example as well as its furthest reach up to date. That part of the article dealt with the building, the nature and extent of the work done in it, the size of the staff employed, the power plant and the electrical generating apparatus. It is now proposed to deal with the distribution of the current and its utilization in running motors, heating, ventilating, lighting, etc. But before entering upon this part of the subject, which embraces the Office as a going concern, which, with the New Year has barely got into full swing, it is appropriate to note the fact that even before there was a new building, Mr. Tapley had to operate his plant for all it was worth, during the trying period of erection. In a rather curious manner, therefore, typically illustrative of the flexibility of electric power, the Office has shown what can be done in building operations with a handy and adequate source of current. For instance, all of the steel structure was raised by electric hoists, and virtually all the brick, mortar and cement and other general building material was elevated in the same way. Electrical pumps were used during the digging of the foundations, for removing the surface water. In the laying of the wood block floor, current was used for heating the mastic which holds the maple onto the concrete flooring bed. Portable saws and other woodworking machinery were supplied with electric drive, and all the planing of the floors was done by specially constructed machines propelled by electric motors. This contract was carried out by Mr. James G. Wilson, of New York City.

Such "distribution" as was required for this special work was necessarily more or less transient and temporary, but from the very first elaborate plans had to be worked out providing for all main and branch circuits in a building of steel, whose iron floor construction is covered with two to four inches of fireproof material, such as concrete, and yet where the work would demand the extension to innumerable points of wires capable of delivering current enough to run extremely heavy machinery. Moreover, two distinct services had to be provided for, light and power, besides which the use of electricity in large volume for elevators, heating, ventilating, etc., made further exactions only to be fully comprehended by a study of the building itself, over whose endless floors one may wander for days, encountering some new application of electricity or electric motor at every turn.

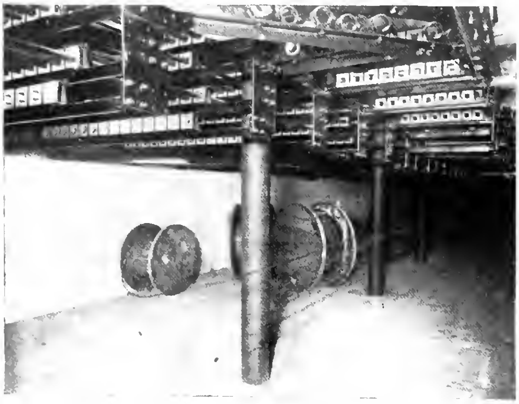

FIG. 12.—CABLE VAULT.

As might be expected, some wiring between floors and walls is enclosed in conduit, as well as at points of emergence around machines, and some idea of the extent of the work involved is faintly indicated by the data given in the report of the chief of engineers, United States War Department, who, by some odd twist of governmental regime, appears to have had the construction of this building under his direction and supervision, although it is obviously one of the most pacific branches of the public service. The figures submitted by Captain J. S. Sewell, United States Corps of Engineers, to General Gillespie, show that up to November 28, the sum of $123,147 had been expended on electric wiring, the work on which, by the way, was done by the electrical force of the Printing Office—a most creditable fact. The scope of the work is also indicated by the material used in the electrical installation, including 13,094 linear feet of terra conduit; 55,068 feet of flexible metal conduit; 14,000 pieces of lead bushing for the flexible conduit; 1,822 iron outlet and junction boxes; 8,248 pieces of enameled pipe; 145,811 fittings of all kinds; 394,375 feet of wire of all classes, or about 75 miles; 1,649 C. S. switches; 91 distributing centers; 1,490 feet of lead tubing and 807 feet of ¾-in. black pipe; 1,490 cut-outs; 2 automatic switches; 1,310 castings of all kinds, and 7 galvanized iron boilers of 30-gallon capacity each, employed with pneumatic door openers. This is no mean bill of supplies.

As a general thing, the column fixtures are the essential feature

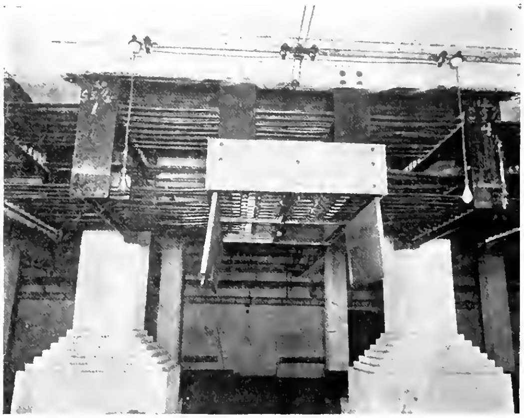

FIG. 13.—LIGHTING DISTRIBUTION CENTER.

of the lighting, but such departments as the composing room and the proof-reading room are a maze of drop lights on flexible cord. Of these applications more anon. It will, however, be readily understood that what is essentially an entirely new system had to be worked out for distributing the electric light and power conductors throughout such a building.

The contract for furnishing some of the wire and cables for the office was made with the Safety Insulated Wire & Cable Company, and amounted to over 100 miles of conductors ranging in size from 1,000,000 cm. to No. 12 B. & S. gauge. The specifications were the most rigid that have ever been received by that company for inside wiring, Article 37 of the contract being as follows: "All rubber wire, both stranded and solid conductors, shall have an insulation of seamless rubber compound, containing not less than 40 per cent. of pure Para rubber, and shall show an insulation test of not less than 1,200 megohms per mile; must be concentric and free from flaws and holes; must have a smooth surface and circular section."

The insulation was guaranteed to stand a rise in temperature of 100 degs. F. above the surrounding atmosphere, and not be affected by either acid or alkaline solutions. It was specified that all wires and cables furnished should be submerged in water for two weeks at a temperature of 76 degs. F., before the insulation resistances were taken. No. 12 wire was used in all cases for circuit work instead of No. 14, as is ordinarily used in commercial installations. The circuit wire was constructed under special specifications drawn by Mr. Tapley, as electrical engineer of the Office, and was designed to withstand not only the exacting electrical heat, acid and alkaline tests, as noted above, but such abrasion as would ensure its safety against rough handling in drawing through the miles of conduits used in the Printing Office. As a special precaution, after manufacture, all of the wires and cables were submerged in water, and an alternating current of 5,000 volts pressure was applied between the conductors and the water. This test showed a factor of safety of fifty times the actual working pressure.

The cable racks shown in the vault extend a considerable distance, and are built up in four tiers and supported, as shown clearly in the cut. All the cast iron and steel parts received either one or two coats of asphaltum paint or japanned finish, and the insulator clamps like all the castings in the work are of a tough, close-grained gray iron. The porcelain insulator blocks are of dense material, glazed and tested to withstand 10,000 volts alternating current without breakdown.

The terra cotta conduit used, furnished by the Potomac Terra Cotta Company, of Washington, D. C., is composed of single duct 24 inches in length, vitrified and glazed inside and out, with exterior dimensions about 4 inches square, and with a hole in the duct 3¼ inches in diameter. Each piece of duct is provided with iron dowel pins. The outlet holes of all tile are 2½ inches. The steel pipe employed is enamel, having a thickness of 1-16 inch evenly applied, leaving a smooth interior wall guaranteed for ten years to be free from cracks and flaking, and with an insulation between metal and enamel equal to 5 megohms. The iron armored conduit of which four or five thousand feet have been used, is ¾ inch with heavy wall. A large amount of flexible iron conduit has also been used, amounting to several thousand feet of ¾ and 1-inch sizes, and it is of the spiralized flexible metallic Greenfield type made by the Sprague Electric Company. A striking illustration of its flexibility is shown in one of the engravings which portrays a run at an elevator shaft, where it has been brought up a lattice column and looped around and across. The circuits thus run through pipe and by means of the vent shafts run to over 1,800 metal outlet boxes, as noted above, all of cast iron with interior insulation, and of a general dimension of 3¼ by 3¼ inches inside measurement, and to switch boxes of corresponding number equipped with C. S. double-pole flush switches made by the Cutter Electric Manufacturing Company, of Philadelphia.

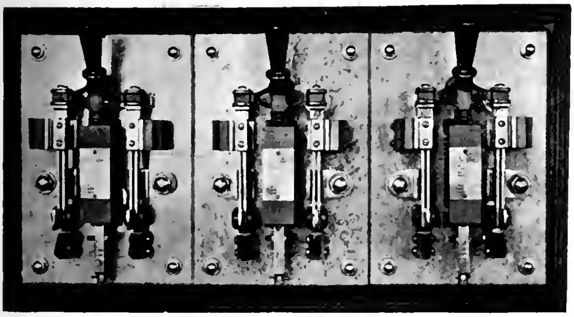

FIG. 14.—DISTRIBUTING CENTER AND CIRCUIT-BREAKERS.

The proper distribution of the electric circuits necessary for supplying both light and power in a modern fireproof structure is a subject that needs much thought and consideration before the final arrangements are decided upon and to the structure itself. This is one of the principal features in the wiring of this building. The general scheme is as follows: There is provided an air space between the ceiling and the fireproof flooring of from 10½ inches, bottom of floor beam to top of ceiling beam to a maximum distance of 19 inches from crown of floor arch to ceiling line. This provides a space where all wires are readily accessible. The selection of the fire proofing and floor construction was finally settled upon as being the best suited to an electrical distribution which has to be constantly changed, that is, there must be means of ready accessibility not only to the power circuits but also to the lighting as well. At the same time the floor construction must not be weakened by having a large number of holes drilled through it, which is necessary as will be seen from the subsequent description of the power and press installation.

The system as a whole might be most properly designated as an open-concealed installation, which is readily to be understood from the illustrations which accompany this article. The auxiliary feeders are all supported upon porcelain insulators carried in specially constructed insulator clamps which in turn are fastened to the three-inch I ceiling beams.

The main feeders come direct from the switchboard to the cable vault where they are carried upon porcelain insulators themselves secured to special iron cable supports thence to the vent shafts which run from the basement to the loft, in which are another type of special insulators fastened to channel iron which are so placed as not to interfere in any way with the main design of these shafts, namely, ventilation of the various floors. It provides, however, a very accessible means of making additions or alterations in either the lighting or power circuits now or in the future without in any way installing new conduits or having to cut the ceiling of the building for such work.

In the basement both in the north and south wings of the building are placed two distributing centers into which the main lighting feeders are connected, from this branch laterally the auxiliary feeders entering ultimately the extreme east and west vent shafts of their respective wings in which they rise to the individual floors, where they enter a specially devised distributing center consisting of three circuit breakers mounted upon a common bus, which in turn is the connecting link of the main floor crib. All floors are wired on the crib system, the center circuit breaker being used as a tie switch, thus allowing double the number of lights to be installed on the crib without any subsequent drop in voltage.

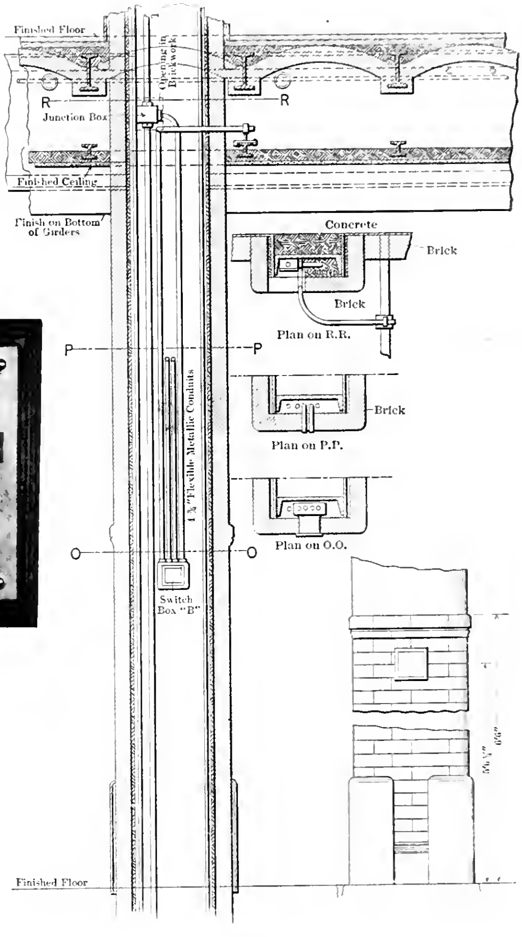

FIG. 15.—SECTIONAL VIEW OF COLUMN, WITH CONDUITS AND SWITCH AND JUNCTION BOXES.

ELECTRIC LIGHTING.

From the main floor lighting crib is made a tap at every column from which the wires are conducted through flexible metal conduit to switches located on the east and west sides of the columns in the building. The switches on the east side control the lights of their respective north and south bays, while the switches on the west side are used for controlling the general illumination, which is obtained by means of 12 lights uniformly distributed around the sides. Two of these lights are used for pilot lighting, which provides sufficient light for the watch force when the Office is not engaged in night work. This pilot system is controlled by one general circuit located in the basement, to which are connected vertical feeders for each column. This pilot circuit is connected to an individual switch on the main switchboard giving the switchboard attendant full control over the lighting system and thus cutting down to a minimum the use of current for this purpose.

The individual lighting throughout the entire building, except in the executive offices, main hall and column lighting as mentioned

FIG. 16.—VIEW IN COMPOSING ROOM.

before is entirely done by means of individual pendant lighting. Each bay, practically 12 ft. by 34 ft., is taken care of by an independent auxiliary crib located inside of the ceiling space to which taps are made wherever lights are desired. Wiring for the individual lighting is figured on the basis of one 16-cp. lamp to every 25 sq. ft. of floor space. In some places, such as composing rooms, this maximum allowance is used, while in others there is not more than one-half of the original proportion in use.

The power circuits are conducted in a similar manner from the switchboard to their respective vent shafts with the exception that there are no distributing centers in the basement, but each power circuit is continuous from the switchboard to its respective distributing center located on the vent shaft near the ceiling of the floor below which it is to feed. The general scheme is for the power circuits to lead up through the floor to the individual motors wherever located while the lighting connections are made to the ceiling of the floor below.

On every floor there are four lateral power feeders extending the entire length of the building from which power is given to individual motors when located within the radius of a few of same. The feeders themselves are in turn connected by ties to the individual circuit breakers located on the distributing centers. The floor girders are 33 inches in depth, extending 10 inches below the ceiling line. Means of providing for these lateral runs through both steel girders and their surrounding fire proofing is accomplished by having the girders punched at the proper place and a steel tubing thoroughly enameled being inserted in this hole and its end projecting 1 inch either side of the fire-proofing of the girders, thus providing continuous porcelain support for the feeders from one end of the building to the other, the supports between girders being special insulator clamps fastened to tie rods 4 ft. on centers. There was installed in the outer walls of the building and in every bay a vertical run of terra cotta conduit having openings inside of the ceiling space and at 6 ft. from the floor at every story. This makes it possible to run wires throughout the entire building with the ability to reach any place desired without having to cut the walls or in any way disfiguring the interior of the building, which is of enameled and white hard-burned bricks.

Mr. Tapley has used throughout the entire installation, with exception of the taps from the auxiliary cribs to switches and their returns, weather-proof wire, thus effecting a saving between rubber and fireproof insulation of a sum sufficient to pay for the cable supports in the basement and vent shafts. This wire being subjected constantly to a warm, dry atmosphere the insulation will be in much better condition ten years hence than had rubber insulation been used for the mains and feeders.

The cost of this system was very much less with regard to both material and labor than had conduit system been adopted. The cost of alterations and additions are practically nothing in comparison to what this would have been had no means been provided of ready access to all wires in the building. In a large institution of this character it is impossible to see ahead three or four years, and thus it becomes necessary to provide some such means as adopted here, unless they were to disfigure the building every time an alteration of lights or of machinery are needed for the benefit of the service. No argument is needed on this score for a careful study of the illustrations shown will demonstrate the great practibility of this system over the ordinary iron pipe installation.

As a general thing, as already noted, the column fixtures are the essential feature of the lighting on all floors, and they are clearly illustrated in many of the engravings as well as in detail. The column fixture is a simple band of metal of plain but graceful appearance, having three lights on each side of the column. It is noteworthy that here as well as in the halls, in fact, throughout the building, incandescent lighting reigns supreme, while, of course, in the halls of the first and second stories, or where the general public has access the fixtures are of a more costly and decorative type, especially at the marble stairway of the front entrance.

Views are also shown of the lighting in the proof-reading and composing rooms, where there is a maze of drop lights on flexible cord supplementing the column fixtures. In the composing room over the type cases, Mr. Tapley has worked out and installed a simple but ingenious device, as shown in one of the cuts, by means of which the possibility of breaking the cord or the lamp is reduced to a minimum. As will be seen the lamp can be slid along a horizontal wire or rod which extends from end to end of the row of type cases, and even if he moves his position only an inch or two, the compositor can at once slide his lamp along the wire and it assumes and keeps the position in which he wants it without any further manipulation or attention. The handle by which the lamp and its shade are shifted about on the supporting wire can be seen over the various type cases.

FIG. 17.—SPECIAL FIXTURES OVER TYPE CASES.

ELECTRIC ELEVATFRS.

One of the most interesting and important parts of the plant is the elevator equipment, to which incidental reference has already been made. The elevator system was designed by Mr. E. R. Carichoff, of the Otis Elevator Company, to meet the special conditions laid down very rigorously in the government specifications. All the elevator mechanism is, of course, installed on the basement floor, and the elevator shafts are designated clearly as to location on one of the plans already published in the first part of this article. The elevator plant consists of thirteen large machines, eight of which are for passenger service and five for freight service, and two form lifts,

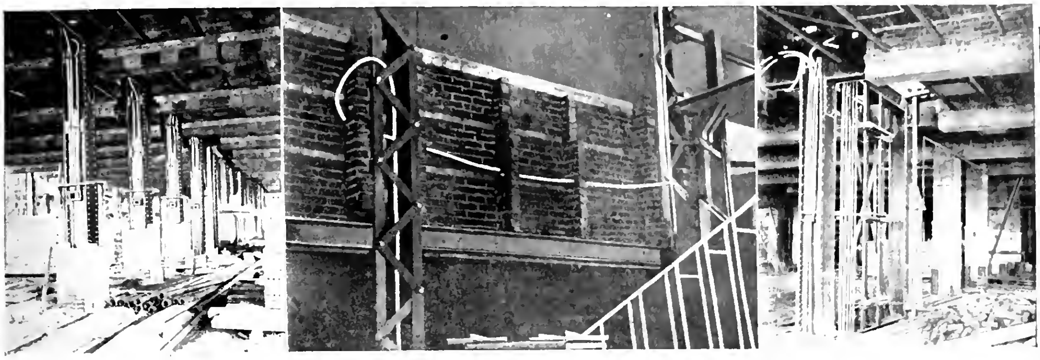

Fig. 18.—Straight Runs of Conduit, Cable Vent Shaft and a Flexible Conduit Loop.

Fig. 19.—Runs of Conduit with Outlet Boxes on Columns.

Fig. 20.—Distribution Crib on Ceiling, and Conduits and Cables in Vent Shafts.

WIRING OF THE GOVERNMENT PRINTING OFFICE, WASHINGTON, D. C.

which are automatic push-button elevators for carrying forms of set up type. The large machines have a capacity of 5,000 lbs. at 350 ft. per minute, and one of the freight machines is provided with changeable back gears at the drum, which increase its lifting capacity to 10,000 lbs. at a reduced speed.

All of the machines are of the worm-gear drive-winding drum type. The worm gears are cut according to the Hindley form, to insure the maximum contact surface. The two worms are cut on one forged shaft, and interlocking spur gears bolted to the side of the worm wheels take up the end thrust of the worms. The taper ends of the worm shaft and the armature enter the face couplings connecting the motor to the worm shaft—one-half of the coupling forming the brake pulley.

A glance at the cut of the isolated machine (Figs. 22 and 23) shows the substantial character of the construction, and also how readily adjustments may be made of brake tension and for wear of shoes. No live parts are exposed at any time, and the motor may be entirely closed or the covers may be removed as desired.

The wires from the motor to the controller run in flexible loom through insulated water-tight ironpipes and less than one per cent drop of potential occurs between motor and controller. Fig. 24 shows a single controller, the parts of which are mounted on two-inch Tennessee marble supported on angle irons from a cast iron base. The two reversing switches are shown near the bottom. The long coil in the centre operates the fingers for regulating the resistance for starting and stopping, and is controlled in both operations independently by an oil retarder.

FIG. 21.—VIEW IN PROOFREADING ROOM.

The small heavy wire coil at the right, near the middle, limits the input of current, and the small magnet at the left varies the field strength and speed of the main motor. On the upper right corner is placed an independent overload no-voltage circuit breaker, which may be opened by the car at extreme limit of travel or by the operator in car in emergency cases. On the upper left corner of the board is a recording wattmeter, which with the counting device attached to the machine permits readings of energy consumed by the machine and feet traveled by the car.

The two reversing switches and the variable speed magnet are controlled by the car switch which is entirely enclosed, self-oiling, and provided with spring return to off position and lock to prevent accidental movement. A covered stop motion switch on the machine brings the car to a stop at the top and bottom of travel. A centrifugal governor switch on the machine forbids excessive speed. The safety grip for holding the car on the rails is operated by a speed governor at the top of the hoistway, and may be thrown on by the operator in the car. This action controls the switches which immediately stop the machine. The guide rails for the car are cold-rolled steel, and are supported every four feet by reamed bolts. The overhead construction work has no holes in the flanges of beams.

The passenger cars have bronze cages and other parts are made to correspond in finish. Throughout the work is of the highest grade, and the operation of the cars is prompt and at the same time exceedingly smooth.

The scheme of motor connections herewith (Fig. 25) shows that one resistance is used for starting and stopping the motor. It will be interesting to refer to this diagram in detail. When all the switches are down the armature is seen to be on closed circuit of low resistance. It will also be noted that a small quantity of current is allowed to pass through the shunt field by the resistance *F R*. This current is less than two amperes on 110-volt circuit, but is

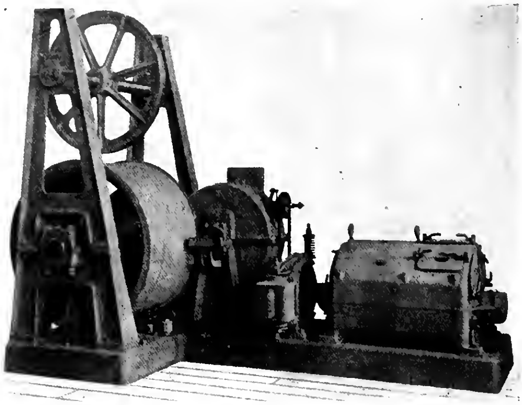

FIG. 22.—VIEW OF SINGLE ELEVATOR.

sufficient in connection with the resistance *S* to provide a dynamic brake for stopping.

Beginning with the switches in this position, the operation may be described as follows: Let the car switch be moved toward up. The first movement sends current from the plus line through the wire - *c* to the car switch, and thence through the contact *U* and the *U* limit to the up magnet, thence through the wire *U*, and bridges 6 and 7 and wire -*c* to - line. The up magnet is now lifted, bridge No. 1 making the circuit from - line to *I*, and bridge No. 2 making the cir-

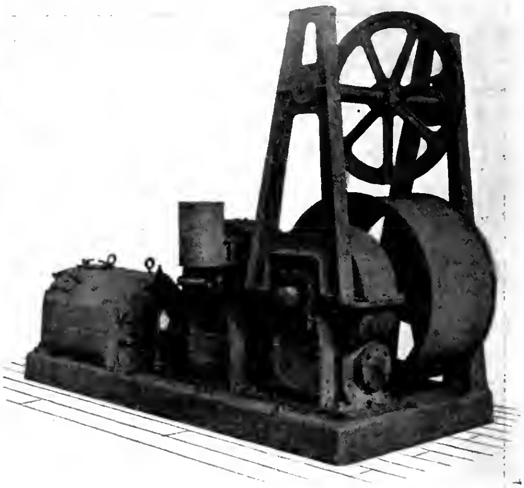

FIG. 23.—VIEW OF SINGLE ELEVATOR.

cuit from - line to *Ro*. The bridge No. 2 being electrically connected to bridge No. 3, connection is also made between the - line and the lines -*B* and -*SF*. Current now passes from - line to the brush *I*, and through the armature to the brush *E*, thence through the regulator brush and resistance to *Ro* and back to - line.

Current also passes from - line through the wire -*SF* to the shunt field and thence through bridge No. 9 to the wire -*SF* and through bridges No. 2 and No. 3 to - line. The brake circuit is also completed from - line through bridges 10, 3 and 2. The regulator circuit is completed through bridges 10, 11, 3 and 2.

Supposing the car switch to remain in the position just described the armature begins to rotate and resistance is cut out by the regulator. The throttle magnet is operated by a series coil in the armature circuit, and should the current become excessive, it lifts breaking the regulator circuit at bridge 11. The regulator then receives current only through the resistance *A. R. T.*, and ceases to move.

When the regulator reaches the top of its movement, it lifts bridge No. 10. This cuts resistance *A. R. B.* into the brake circuit, and resistance *A. R. S.* into the regulator circuit, so that these coils do not become heated. The bridge 10 also completes the circuit to the fast speed magnet, so that if the car switch is now moved so as to send current through contact *F*, the fast speed magnet will be lifted cutting in the field resistance. The motor then runs with increased speed and weakened field. Should the car switch be turned at once to "full speed," the fast speed magnet cannot operate until the regulator has completed its upward movement.

As the car switch is returned to the central position, either by hand or by the action of its own centralizing spring, the fast speed and the reversing switch magnets are demagnetized and fall, placing the armature in a closed circuit of high resistance, the resistance brushes being now at the top of their travel. The regulator is retarded in its descent, so that the resistance in circuit is gradually reduced until the circuits are as shown in the diagram. This action affords a gradual dynamic brake.

It is seen that the reversing switches cannot be operated unless the resistance brushes are at the lowest position where all the starting resistance is in circuit, as soon as one of the reversing switches is energized.

Resistance tubes of suitable capacity are inserted in the operating coils after action, so that the temperature rise is hardly appreciable. This and the mode of winding of coils insures absolute indestructibility. The contacts are of ample capacity, readily renewable as will be seen by a glance at the engraving of the controller. Indeed, some of the elevators have been in operation for a year, and experience so far indicates that the cost of maintenance will be almost nothing.

Reference has also been made to the two form lifts of the "push-

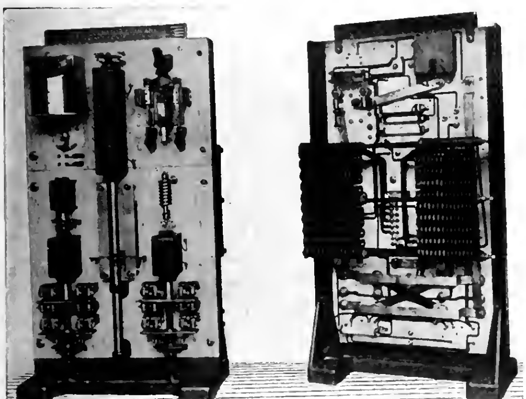

FIG. 24.—VIEWS OF ELEVATOR CONTROLLER.

button" type, operating between the composing room and the pressroom floors. These were also supplied by the Otis Company. On the form lifts exact stops are made from a speed of 300 ft. per minute by the automatic slowing device, which operates only at the landing for which the car is destined. At the same floor a signal lamp remains lighted and the car is held until the load is removed or put on and the door closed, when the car may be directed to any other floor. The total lift is 100 ft. The hoists are provided in permanent elevator shafts, housed in well above the floor, and are each equipped with a 10-hp motor, 110 volts, direct current. The cars are 4 ft. by 6 ft. 6 in., so that a large "chase" can be handled quickly; and it will have been understood from previous passages in this article that the hoists are a material factor in securing the great dispatch with which much of the work is executed.

ELECTRIC HEATING APPLICATIONS.

Perhaps the application of the motors to the presses might be considered next to the elevators, but there are one or two other branches of service of equal interest if not equal scope which fall in place here for treatment. Most striking and noteworthy of these is the use of electric heating. Unless we are greatly mistaken Mr. Tapley has in service one of the largest electric heating systems in the world; certainly the largest that is known in the field of printing and publication. Here again the work is characterized by a great deal of originality and thoroughness, for which the staff, in conjunction with Mr. W. S. Hadaway, Jr., engineer of the Hadaway Electric Heating & Engineering Company, of New York City, must be ascribed great

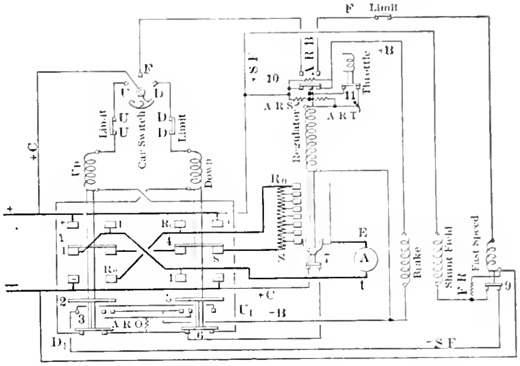

FIG. 25.—DIAGRAM OF MOTOR CONTROL USED ON ELEVATORS.

credit. The uses of electric heat in the office fall broadly into two groups or classes. One of these embraces the foundry and includes matrix drying tables, wax stripping tables, wax melting kettles, case warming cabinets, "builders' up" tool heaters, case warming table, wax knife cutting down machine, "sweating on" machine, and soldering iron heaters. The other class in the bindery includes embossing and stamping press heads, glue heater equipments, glue cookers, case making machines, finishers' tool heaters, book cover shaping machines. This is a remarkable range, but in addition and outside these divisions we find the pamphlet covering machines, the sealing wax melters and some other devices. It is only when one sees such an equipment as has been devised for and brought together in the Government Printing Office that one grasps fully the idea of the extraordinary flexibility and utility of electric heating. Such heating may not yet take care of a big building, but in such special applications as these it cannot be surpassed or equaled for efficiency and economy.

The equipment of these electrically heated appliances in the Office supplants gas and steam in all processes excepting the stereotype melting pots which are heated by gas. Practically all apparatus was made from new designs by Mr. Hadaway with careful attention to mechanical details, and with large factors of safety electrically. The specifications of the controlling appliances were rigid, and necessitated new switch designs giving great strength and durability. The switches, seen on the wall in Fig. 28, are mounted upon slate slabs and protected by iron covers, all connections being soldered to lugs. The slabs are mounted upon iron or slate bases so that every precaution may be taken against accident.

In cases where working temperatures are moderate, the apparatus is operated on 117 volts. Where high temperatures and rapid rates of impartivity are required lower variable voltages are used. These are secured by translating appliances consisting of rotary converters and transformers with several taps on secondaries. The extreme ranges of energy density in various appliances are from 0.75 to 40 watts per square inch superficial area.

The Matrix Drying Tables.—These are employed for preparing the matrices used in printing the *Congressional Record*. The bed is supported upon a massive pedestal to which an apron is attached. The platen is controlled by a heavy double screw in yoke bolted to the pedestal. The bed and apron are heated, each having separate controllers. Great care was necessary to secure a uniform temperature over working surfaces.

Wax Stripping Tables.—After the cases have been used to make electrotype shells, they are put upon the stripping tables which melt

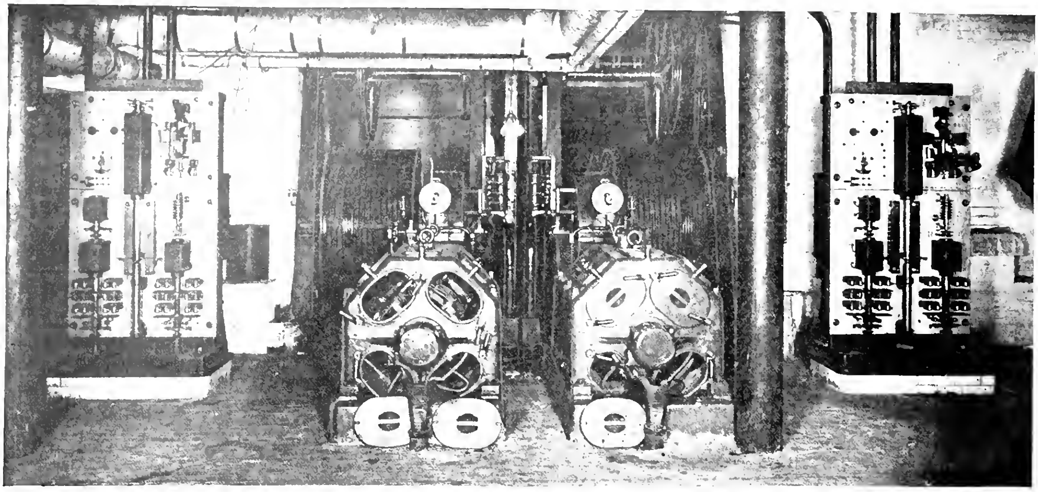

Fig. 26.—View of Double Elevator Equipment.

the wax. The wax is collected in a gutter, which empties into the wax kettles. A variable temperature within moderate limits is desirable according to the amount of work to be done.

Wax Melting Kettles.—The wax is collected in these from the stripping table and freed from graphite and dirt and freshened and tempered. A pair of kettles are placed side by side and attached to a drip pan to facilitate this process. The drip pan is attached to the stripping table on one side and to a pouring table on the other side. The heaters are arranged to give equal temperatures to the walls of the kettles and to prevent scorching and unnecessary destruction of the volatile elements in wax.

Case Warming Cabinet.—Before the cases are put under hydraulic presses, the wax is softened at a moderate temperature so as to give accurate impressions. The warming cabinet is a chamber with racks in which a number of cases may be put to soften the wax. Electric heaters are so distributed as to give a uniformly diffused heat throughout the chamber.

Case Warming Table.—In the case warming cabinet the wax is softened equally throughout. The case warming table is designed to heat the case on the upper surface only so as to secure a firmer backing. A heated plate is placed horizontally above the table upon which the cases rest with the wax films upward. The heating is effected by radiation from a uniformly distributed energy surface.

Wax Knife Cutting-Down Machine.—After the cases have been under the hydraulic presses, the wax is uneven and ragged around the impressions. This machine has a movable bed upon which the case rests. It is then passed under a carefully heated knife, which removes all projections without defacement. This is an instructive example of the greater refinement in processes which has been made possible by electric heating.

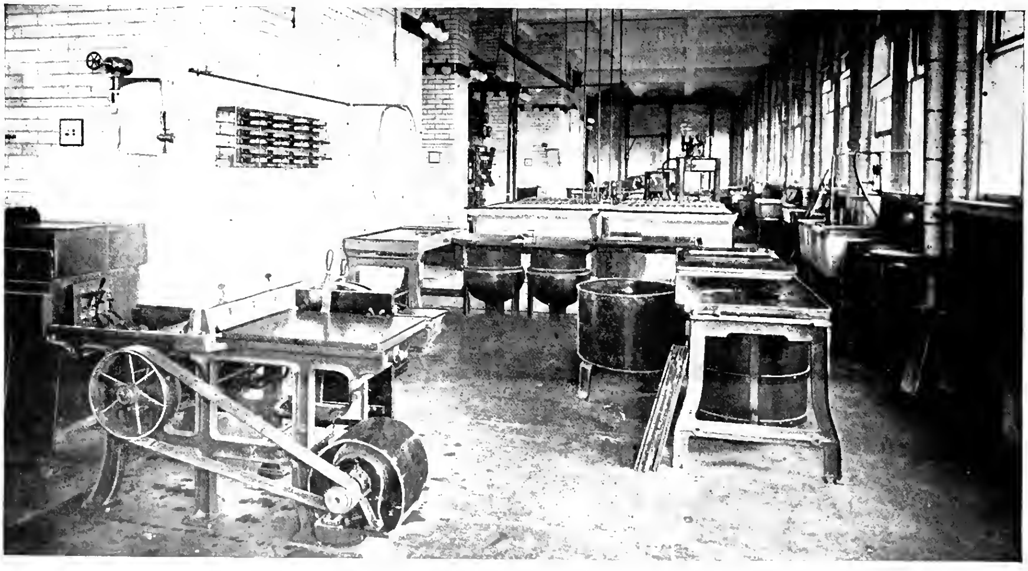

Fig. 27.—Wax Shaver and Wax Heating, Electric Heating Department.

Builders'-Up Tool Heaters.—Before the case is put in the electroplating bath, it is necessary to build up parts of the surface by melting wax to run upon different points. This is done by heated copper tools. These tools are heated upon hooded electric stoves provided with broad tool supports.

Sweating-On Machine.—In some classes of work, it is more desirable to mount electrotypes upon metal backs than upon boxwood blocks. Stereotype metal blocks of equal thickness are heated upon an electric plate with a film of solder and flux between the block and the electrotype. When the solder film is melted, the block is placed under a light press which cools it under pressure. An electrically heated plate makes this process economically possible owing to equal temperatures over the whole surface, so that several electrotypes may be sweated on to their respective blocks at once.

Soldering-Iron Heaters.—To correct electrotypes and insert new letters, it is necessary to use light soldering irons heated very hot. Electric soldering irons with cords attached had been found unsuitable for this work. Soldering-iron heaters capable of running continually at a high temperature were then adopted. The heat is controlled by varying the voltage. The coppers are inserted in pockets to be heated, each heater having two pockets.

Embossing and Stamping Press Heads.—Stamping and embossing require a variable, uniform temperature in the press heads to increase the production to a maximum. The heads have to be strong and the heaters uninjured by shock. Each press is equipped with a heated head and controller complete.

Glue Heater Equipments.—The glue heaters are inserted flush in the benches. The water bath and glue pot are removable. A cover is provided which leaves the bench smooth for stacking books to be bound when the water bath is taken out and the cover put on. A hook is arranged on the bottom of the heater for alternately holding the cover and the water bath, and the glue pot. The heaters are of minimum heat capacity, and heat by conduction and convection in an insulated chamber.

Glue Cookers.—Glue can be prepared in large quantity in these cookers so that there is no need for the men to waste time waiting to make glue in small quantities. Large kettles are fitted steam tight in a chamber built according to low pressure boiler specifications. The apparatus is supplied with water seal, gauge glass, blow-off valves, etc., complete. The heater is designed for maximum working surface so as to be rapid in operation.

Case Making Machines.—Book covers or cases are rapidly glued together in these machines. A large shallow glue pan is heated by a water bath to which electric heaters are attached. These heaters are in sections for facility of control and temperature regulation.

Book Cover Shaping Machine.—The book covers are rounded at the back by machine so as to be smooth and of uniform appearance. In rounding, as for example, the backs, the glue has to be softened so that the case will retain its proper shape. As the rate of working is fast, a high temperature is necessary to secure the proper relation of heat to speed.

Finishers' Tool Heaters.—In gilding and in burning sheepskin for finishing covers of various patterns, tools of varying sizes and shapes are employed. The temperature range is very great. The maximum is high enough for pyrography, the minimum affords a low heat for gilding. Where pyrographic heat is required, small recessed plates are heated very hot upon which tools of varying design are heated

FIG. 29.—VIEW IN ELECTROTYPE FOUNDRY.

by conduction. These heated plates are controlled by variable voltage. In addition, removable plates are provided to accommodate the several patterns of tools employed. It may be noted that in the branch bindery at the Library of Congress, the heated plates are placed vertically above each other in an insulated chamber, with projecting flanges for supporting handles. Variable temperatures in the chambers are secured by varying the amount of heating surface.

Pamphlet Covering Machines.—The pamphlets prepared in infinite number are covered by machines which rapidly glue the backs and place the paper covers on. The backs of the pamphlets are glued by passing over a wheel which turns in a large shallow glue pan.

FIG. 28.—ELECTRIC HEATING DEPARTMENT. FIRST ELECTRICALLY-HEATED MATRIX PRESSES EVER MADE.

The glue pan is of heavy construction and so designed with relation to mass and heater surface as to require no water bath.

Sealing Wax Melters.—These are small heated tools used to melt sealing wax in situ and smoothe the wax so as to prepare it for the seal giving a neat, strong wafer.

Work on this large and unique installation was begun in a conservative way in 1898. Each year, as results became conclusive, small additions in various lines were tried. The sole consideration aside from durability of heating appliances and depreciation factor, was whether a variable controllable temperature increased production sufficiently to pay for the greater cost of the heat required. The answer was in the affirmative, and electric heating appliances have now been used in every process requiring heat excepting the stereotype metal pots.

A great number of heaters are used, and in so large an installation the depreciation of every part of every heater must be considered. Very large factors of safety have been allowed. In high temperature work the energy has been translated to voltages giving maximum mechanical strength to resistances and ensuring effectiveness in operation. This may be likened to the transformations necessary in energy for electro-plating.

An installation representing years of study along this line involves many new features, and it is believed that more attention has been paid to the salient features embodied in this apparatus than in any electric heating installation hitherto made. This treatment of the subject, while it may appear long, is, in fact, very superficial, but is limited by considerations as to the general scope of the present article. As a matter of fact, the electric heating plant of the office is from its novelty and its bearing on a still undeveloped branch of the electrical arts and industries worthy all the space here devoted to the electrical equipment of the office as a whole.

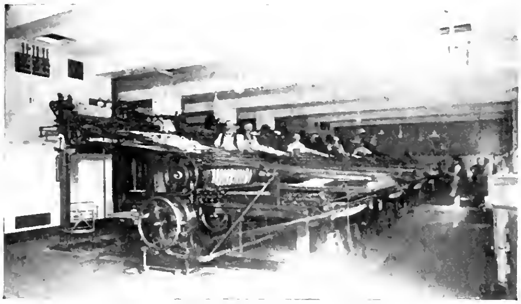

FIG. 30.—A PRESS ROOM SHOWING DISTRIBUTING CENTER AT VENT SHAFT ON WALL ABOVE PRESSES FOR POWER, AND LIGHTING CENTER AT EXTREME RIGHT OF CUT.

Power Signaling on British Railways.

The following from the London *Times* is forwarded by U. S. Consul Mahin, of Nottingham, England: "Three distinct systems of power signaling are now engaging the consideration of British railway managers. These are (1) the all-electric, (2) the electro-pneumatic, and (3) the pneumatic. The first-named system has been adopted by the London & Northwestern Railway at Crewe, and also by the Northeastern Railway Company at its Severus junction box, York, while the Northeastern Railway at Tyne Dock, the Lancashire & Yorkshire Company at its new station at Bolton, and the Great Eastern Railway at Bishopsgate Street goods yard have installed the Westinghouse electropneumatic system. The third system—the pneumatic low-pressure—has been installed on the London & Southwestern Railway, while it is announced that the Northeastern Railway, which has already experimented with the first two named systems, has now arranged for an installation of the low-pressure pneumatic signaling, in order to arrive at the relative merits of the three systems of power signaling on the market. The Great Central Railway Company, which is about to equip its Woodhead Tunnel with the 'Miller' electric signals, has recently placed a contract with the British Pneumatic Signaling Company for the installation of pneumatic signaling in the neighborhood of Manchester."

Annual Meeting of the American Association for the Advancement of Science.

The fifty-third annual meeting of the American Association for the Advancement of Science convened in St. Louis on December 28, under the presidency of the Hon. Carroll D. Wright. After the usual addresses of welcome, the association resolved itself into its various sections to listen to the addresses of the retiring vice-presidents. Prof. E. F. Nichols, the retiring vice-president of the Section in Physics, was unable to be present, and Section B united with Section D, Mechanical Engineering, to listen to Prof. C. A. Waldo, of Purdue University, on "The Relation of Higher Mathematics to Engineering." The essential feature of this address was that calculus should be taught largely through an analysis of its application to practical problems in physics and engineering. In this manner the student had better become acquainted with calculus as a working tool.

The retiring president of the association, President Ira Remsen, of Johns Hopkins University, gave a very scholarly and interesting address on "Scientific Investigation and Progress." He explained how the association was accomplishing its purposes through these migratory annual meetings, where large numbers of scientific men gather for intercourse. This intercourse stimulates thought, the thought leads to work, and the work leads to greater usefulness. He then spoke of the benefits which chemistry is bestowing upon mankind, especially in connection with the raising of food stuffs and the discovery of new medicines and other disease preventives.

On Tuesday and the three following days the several sections listened to the reading of technical and scientific papers by the members. The sections of Physics and of Mechanical Engineering usually have many papers of electrical interest. But at this meeting there seems to have been little of special interest to readers of this journal presented before the Mechanical Engineering Section. Before the Section in Physics, presided over by Prof. E. H. Hall, of Harvard University, there were presented in all thirty-seven papers, about half of which were concerned with electrical subjects. Among the more interesting of these papers the following may be mentioned:

"Iron Losses in Loaded Transformers," by Prof. E. S. Johonnott, of Rose Polytechnic Institute. When a differential coil is added to a Rayleigh phasemeter, it is adapted to the measurement of iron losses in a loaded transformer. It was found that in a transformer having great magnetic leakage, there was an apparent increase in the loss of energy in the iron in the secondary, and decrease in the energy loss in the primary. If a transformer in which there is little leakage has the load in the secondary increased, the loss of energy in the iron and the exciting current and its phase with respect to the induction, remain constant.

"A Simple Alternate-Current Frequency Recorder," by Prof. E. S. Johonnott, of Rose Polytechnic Institute. To one pole of a simple electromagnet is attached a light armature, which is held at some distance from the other pole by a stiff, flat spring. If an alternating current is sent through the coils, it causes the armature to vibrate with a frequency twice that of the current. A smoked-paper recording device may be arranged to receive the trace made by a style attached to the armature, and also the marks from a pendulum or tuning fork. The frequency may then be counted. The current through two incandescent lamps in parallel on 100 volts is sufficient to operate the apparatus.

Another paper was "On the Velocity of Light in a Magnetic Field," by John Mills, of Western Reserve University. The experimenter undertook to measure the acceleration or the retardation experienced by a circular component traversing a magnetic field. The apparatus consisted of a Michelson interferometer. In the path of each beam was placed a tube of carbon disulphide surrounded by a solenoid. The light passed through a Nicol prism and a Bravais double plate. Half of the fringes were thus composed of light circularly polarized in a direction opposite to those of the other half. The formation of a magnetic field produced a shifting of the two sets in opposite directions. The current causing a shifting of one full band (corresponding to a difference in phase of 360°) was observed. On the assumption that the rotation of plane polarized light is the result of a difference of phase between its circular components, the difference of phase corresponding to this value of the current was calculated. It was 368°. The readings for the current giving a displacement of three bands (that is a difference of phase of 1080°) corresponding to a difference of 1101°, calculated.

"A Method for the Determination of Mutual Induction Coefficients," by Augustus Trowbridge, of the University of Wisconsin. If a pair of coils are joined in series and are so placed that the magnetic tubes of force of one thread through the other, the self-induction of the pair is $L_1 + 2M + L_2$. Upon reversing the current through the coil, the self-induction is $L_1 - 2M + L_2$. The coefficient of mutual induction, M, may be found by measuring the two quantities mentioned by means of a bridge method.

"On the Electrical Resistance of Hydrogen-Charged Palladium," by Prof. W. E. McElfresh, of Williams College. This paper will appear in full in the *Transactions* of the American Academy. "A Remarkable Distribution of Carbon on the Bulb of a 'Hylo' Incandescent Lamp," by Prof. Arthur L. Foley, of Indiana University. On the bulb exhibited there are peculiar band and ring deposits, which are dark and of uniform density, while the other portions of the bulb are perfectly clear, the line of separation being as clear as though laid on with a brush. The theory of molecular shadows and the "Edison effect" explains the general character of the deposit, but does not explain the peculiar shapes and the sharp outlines. An attempt to age a number of similar lamps by subjecting them to a high voltage, a uniform deposit quite unlike them are described.

"On the Use of Nickel in the Case of the Marconi Magnetic Detector," by Prof. Arthur L. Foley, of Indiana University. The various forms of sensitive detectors of recent construction were described, and the effect of varying proportion of nickel in the Marconi form was considered.

"On the Charges Given to Surfaces by the Diffusion of Ions, and the Earth's Negative Potential," by Prof. John Zeleny, of the University of Minnesota. Experiments were made showing neutral ionized air in passing through a long tube at first gives a negative charge to the tube, and farther along it charges the tube positively. If the tube is short, only the first effect is obtained, the air itself coming out with a positive charge. Dry carbonic acid gave the same effects, while saturating the gas with water vapor caused phenomena with reversed sign. The results are explained by supposing the charges to be produced by the unequal rates of diffusion of the two ions. These experiments confirm Geitel's explanation of the earth's negative potential.

"On the Differential Telephone," by Prof. William Duane, of the University of Colorado. Two separate coils are wound on the bobbin of a telephone receiver; there are adjusted to have equal resistances and equal self-inductances, and so that their magnetizing effect is zero when equal currents pass through the coils in opposite directions. The coil whose self-inductance is to be measured is connected in series with one coil, and a variable standard of self-inductance in series with the other. A non-inductive resistance is connected to that series having the least resistance, and the two series are connected in parallel and an alternating e.m.f. is applied to the branch points. It will be possible to adjust the several factors of the circuit so that the sound in the telephone vanishes. The unknown self-inductance may be determined to one part in five thousand.

"A Continuous Method of Steam Calorimetry," by Dr. Joseph H. Hart, of the University of Pennsylvania. The continuous method of steam calorimetry here outlined is capable of measuring readily latent and specific heats of fluids with a degree of accuracy seldom attained by other methods, even though they be made with the greatest refinement in the method and observations. If a stream of water at a temperature of T_1 be passed through a worm immersed in a steam bath and emerges at a temperature T_2 the quantity of heat absorbed is $m\ S\ (T_2 - T_1)$, where m is the mass of water passed through and S the mean specific heat of water between T_2 and T_1. If the heat absorbed by the water is obtained by direct condensation of steam alone we have the equation:

$$M\,L = m\,S\ (T_2 - T_1).$$

Where M is the mass of the condensed water and L the latent heat of condensation of steam. If either L or S is taken as known, the other may be readily obtained. Barnes' values of S were taken and a number of determinations of L made to test the efficiency of the method. In the practical development of the method, the process was made continuous. The water in the worm and the condensed water was drawn off constantly and measured. Radiation and conduction entered as important factors in the construction of the calorimeter, but were eliminated or at least satisfactorily accounted for in the amount of condensed water, both by theory and practice. Results were obtained in consecutive experiments, which were concordant to the fifth significant figure.

Perhaps the most interesting event of the meetings was a popular lecture on "Radium and Radioactivity," by Prof. E. Rutherford, of McGill University, Montreal. He had given two scientific papers before the Physical Society, in which he described some new and important phases of his researches on the properties of radium. In his popular lecture he described and illustrated these discoveries, besides giving a general account of the discovery and properties of radium. A golf-leaf electroscope was arranged for projection, and with this the discharging effect of radium was strikingly exhibited, the sample of radium used being thirty milligrams of pure radium bromide. The interposition of a plate of iron two inches thick only slightly reduced the effects. It was demonstrated that when radium is heated there is liberated an emanation which, when conducted through a tube to the electroscope, the latter is discharged. Prof. Rutherford described a differential air calorimeter with which he had verified Prof. Curie's discovery that a gram of radium gives out heat at the rate of a hundred calories per hour. He has proven that this energy resides in an emanation which may be driven off by heating, and which can be condensed by liquid air. This was demonstrated upon the stage. This emanation seems to possess all the energy, and leaves the radium without energy. The emanation seems to be gaseous, possibly is helium, and can be preserved by itself. It gradually loses its energy, while the inert radium regains its former activity. These changes proceed in a geometrical progression, the recovery being about one-half in four days, with a practically complete recovery in a month. It was computed that one gram of radium gives off 6×10^{-6} cubic centimeters of emanation; and that a pound of this emanation would be able to give out energy at the rate of 10,000 hp for six days, an amount sufficient to drive a steamer across the Atlantic. It was suggested that radium might prove useful in the treatment of cancer and of consumption, though at present there is little definite information upon these points. The lecturer referred to the undoubted presence of radium in the earth and in the sun, and suggested that Lord Kelvin's "distressing theory" that the sun's heat would be exhausted in 60,000,000 years might be disproved; and that it might possibly be the presence of radium in the soil which causes an increase of temperature towards the center of the earth. The experimental parts of the lecture, involving the use of the lantern, the induction coil, liquid air and much accessory apparatus were very successful. The entire audience was able to see the luminosity of the radium itself, and its induced radioactivities on various mineral substances. An artificial "spinthariscope" gave a vivid impression of the wonderful sight exhibited by this small instrument.

The American Physical Society held its annual meeting in connection with the association. Twelve papers were read before the society, several of which are mentioned above. The president was Prof. A. G. Webster, of Clark University, who was re-elected president for the coming year.

Among those elected Fellows of the Association (the highest grade of membership) are E. S. Johonnott, professor of Electrical Engineering in Rose Polytechnic Institute; Henry Crew, professor of Physics in Northwestern University; A. S. Langsdorf, professor of Electrical Engineering in Washington University; C. M. Knight, profesor of Physics in Buchtel College, and Bernhard A. Behrend, of Cincinnati, member of the American Institute of Electrical Engineers.

The number of members registered at the meeting was 385; this number does not, however, fairly represent the attendance, for the many affiliated scientific societies were attended by other scientists not included in the above. The attendance at the sessions of the Physics Section was usually about 75. While the Middle West was very adequately represented, there were many prominent members in attendance from the East and New England, as well as from the Pacific coast. Upon the whole, the meeting was very successful, and it was enjoyable and profitable for all present. The local committee of St. Louis provided a most hospitable entertainment for their guests, which was duly appreciated. One afternoon the whole association visited the World's Fair, as guests of the management. After a lunch the members inspected the spacious grounds and the many beautiful buildings now nearing completion.

The next meeting of the asociation will be held in Philadelphia, beginning December 28, 1904. Prof. W. F. Magie, of Princeton, will preside over the Section in Physics and Prof. D. S. Jacobus, of Stevens Institute of Technology, will be the presiding officer of the Mechanical Engineering Section. It is thought that the meeting for 1905 will be held in New Orleans.

Gas Power for Central Stations.

At the December meeting of the American Institute of Electrical Engineers, Mr. J. R. Bibbins in a paper entitled "Gas Power for Central Stations," discussed the operation of electrical generating stations in connection with gas works, and presented in the form of curves and tables much interesting data relating thereto. Owing to limitations of space we are obliged to omit the tabular matter, which is, however, available for reference in the *Transactions* of the Institute.

In opening Mr. Bibbins stated that his object was to offer evidence that present gas-power machinery is suitable for central station service; that a well-equipped gas-power electric plant can operate with far better economy than a steam plant under similar conditions; that its operation is much simpler and requires less running expense for the same results; and that gas works laboring under low load or output factor, can profitably install a gas-power electric generating station, and become its own largest customer, selling both gas and electricity at comparative rates.

The basis of the paper consists of data collected from various electric light and power plants in the United States using gas engines as their principal motive power, a number of which are operated by gas companies.

Tables accompanying the paper gives the data of 15 plants. Of these 12 are located in centres ranging from 2,000 to 25,000 population, and where in most cases the cost of fuel is high. The equipments average 315-hp capacity, and operate a variety of types of generators for arc and incandescent lighting and for railway or general power service. All the generators are belted, the majority directly, but a few through the medium of a jack-shaft, the latter arrangement being employed in order to obtain the desired flexibility of service without installing a number of engines of small size. The other three plants are somewhat larger and generate polyphase power for industrial works. These three plants average approximately 570 brake hp and the units are all direct-connected and run in parallel.

In general, the character of electrical equipment is not all that could be desired for furnishing results of great accuracy; but owing to the more or less uncertain calorific value of the fuel-gas used, errors of a few per cent. in particular cases will not have much effect upon the general result. In any event, the average cost of power charged against the station is the desired figure.

A 65-hp two-cylinder vertical engine of the type employed in the plants reported on has made the following record in fan-blower service: In a period of 8,472 hours, the stoppages were 242 hours, or 3 per cent., 0.6 per cent. of which was chargeable to the engine in changing igniters and setting up bearings. During this period the engine ran, without stopping, 1,157 hours, and was then shut down to repair a broken belt.

In a pumping station located on the Allegheny, a short distance from Pittsburg, five 85-hp engines of the same type operate regularly at full load through the week without stopping, except on Sunday, when the units are shut down in rotation for inspection and repair. Each engine operates from 96 to 98 per cent. of elapsed time. Such service would not be required in central stations, as reserve capacity should be available for use during peak-loads. In the present exhibit, the majority of the plants operate from 18 to 22 hours per day, giving ample time for inspection and repair, even if no reserve capacity were provided.

The skill required for operating a gas plant is apparently no greater than for steam plant. In several instances where the latter have been replaced, the old employees have been retained. In newly established plants steam engineers have invariably taken charge after short preliminary instruction from the builders' erecting engineer.

In one plant weekly inspection of bearings, igniters, and valves were at first carried out. This was found to be unnecessarily frequent and is now done once a month. The cylinders are inspected occasionally throughout the year. This plant, 800 hp capacity, is operated by three day men and one night man, ten hours to a shift.

In cost, the gas-engine equipment is quite comparable with that of a steam plant. The engine itself costs more than a steam engine of corresponding size, on account of the increase in metal required by the higher pressures dealt with. With the cost of condensing machinery charged to the steam-engine, however, this disparity is much reduced. With natural or illuminating gas supply available, the equipment cost would fall considerably below that of a steam equipment of boilers, engines, condensers, heaters, pumps, etc. In the case of a producer gas plant installed to supply the gas engines, the cost of the respective equipments, each of 1,000 hp, is at a parity, although depending somewhat upon the gas storage capacity provided. This, however, amounts to much less than electric storage. For producer gas the former costs in the neighborhood of $7.35 per hp hour and the latter $100. Considering the increase in productiveness of labor which is stated by a prominent gas engineer to be fully 100 per cent. (owing to the fact that one man can handle twice the amount of coal), the advantage, if any, held by the steam plant, disappears.

In economy of fuel, the gas engine admittedly has no rival. The present limit of steam engine practice is 10 pounds water per ihp, or 11 pounds per bhp. With an evaporation of 10 pounds of water per pound of good coal (14,000 B.T.U. per pound), a performance of 1.1 pound coal, or 15,400 B.T.U. per brake hp is realized. The gas engine at present delivers, at full load, a brake hp upon 10.5 to 11 ft. of gas (of 900 to 1,000 B.T.U. per cu. ft., calor,ic value) which is equivalent to 10,000 to 11,000 B.T.U. per brake hp; Fig. 1 shows a typical test-log upon a 550-hp engine of the three-cylinder vertical type, employing the four-stroke cycle. The thermal efficiency shown is the true or "kinetic" efficiency, namely, the ratio of the input to the output, or the thermal equivalent of the work done to the thermal value of the gas.

At full load this appears at 25 per cent., and considering that the theoretical limit of gas engine efficiency is yet only approached, and the fact that the theoretical efficiency of a steam engine working

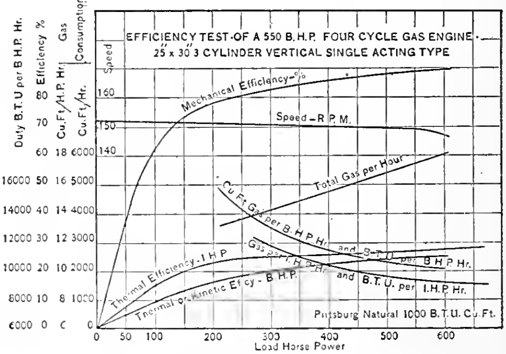

FIG. 1.—EFFICIENCY CURVES OF FOUR-CYCLE ENGINE.

between the usual units of 150 lbs. boiler and 3 lbs. condenser pressure has already been exceeded, there appears to be an encouraging future for internal combustion motors.

Mr. Bibbins summarizes the advantage of the gas engine for central stations as follows:

1. Minimum fuel and heat consumption. 2. Light load efficiency higher than steam engine of corresponding size. 3. Low cost of operation and maintenance. 4. Simplification of equipment. 5. Small number of auxiliaries required. 6. Absence of "standby" losses. 7. Quick starting. 8. Waste heat in jacket water suitable for building heating. 9. Ease of extending equipment. 10. Absence of high pressure except in engine cylinder. No danger from explosion outside, as a mixture of proper proportions is required. 11. Power can be stored during light loads at small cost in the form of gas in holder. 12. Sub-division of units more easily accomplished, yielding higher all-day economy.

An important source of economy in gas plants is the fact that as soon as an engine is shut down all heat losses cease. Also, during operation no heat is lost by the gas in transit from the producer, and the plant is not hampered by inefficient auxiliaries such as steam pumps, condensers, return traps, etc., all of which largely increase the general complexity of the system. Steam pipe and cylinder condensation losses, radiation, leakage in piping, and fuel loss in banking fires, have no parallel in the gas plant. The only auxiliaries required are the igniter generators, and air compressors. The former are negligible as affecting the economy of the station, and the latter operate at full capacity at regular intervals. In cases where artesian wells supply jacket water, a pump is of course required, preferably operated by a motor or small gas engine to which the air compressor may also be belted.

In quick starting, the gas engine fulfils every requirement. The 280-hp pumping units of the Philadelphia high pressure fire system have been repeatedly started cold, brought up to speed and the pumps loaded to the required pressure (300 lbs. per sq. in.) within a period of 40 seconds from the starting signal. In another plant employing 133-cycle high-speed generators, the units are regularly started in two minutes, and this may be reduced to one minute in case of necessity.

A number of plants make use of hot jacket water for heating offices and buildings, ordinary cast-iron or coil-pipe radiators being used for this purpose. One station partly supplies a municipal heating system resembling the Yaryan, thereby deriving direct revenue from a waste product. Part of the return water is sent again through the jackets, the temperature being lowered to the proper degree by adding fresh water from the station supply main. Another station returns hot jacket water to a large cistern where it partially cools and is again pumped through the jackets emerging at a temperature of 200° F. before being discharged into the sewer. As return water from a heating system is also discharged into this well, a small amount of cold water from artesian well or city water system is added from time to time, to reduce the general temperature of the circulating system. In another plant, the jacket water is utilized in winter for warming the water in the gas holders to prevent freezing. This was formerly done by using live steam from a boiler used in making water gas. It is estimated by the manager that a saving of $250 per year is effected. In locations where water is expensive, a small cooling tower may profitably be installed to cool the jacket water which may then be saved.

In the matter of parallel operation of alternating-current generators, the three larger plants noted have been distinctly successful, particularly in view of the variable character of load incidental to large industrial works operated by induction motors. All the units are of the direct-connected type with standard fly-wheels. A spring coupling provides a flexible connection between engine and generator, to absorb cyclical speed variations. The usual copper dampers on the pole pieces assist in preventing hunting. In general. a low frequency seems to be desirable, with high peripheral speed and moderate reactance in the generator to assist in damping current fluctuations. The suddenness of the impulse in a gas engine cylinder offers, to be sure, greater difficulties than in the case of a steam engine, but the remedy has apparently been found.

The following table is given of the calorific values of different gases suitable for gas engine use. The first column gives the calorific value in B.T.U. per cubic foot for the gas itself and the second column the calorific value for the working mixture:

Natural gas	1000	91.0
Coal gas	650	91.7
Water gas	300	88.0
Carburetted water gas	600	92.0
Producer gas	120 to 145	60 to 68
Coke oven gas	600	90.0
Blast furnace gas	90	53.0

The power to be developed by an engine of given proportions does not therefore vary within appreciable limits, except on producer gas and blast-furnace gases, when larger engines are required, or larger cylinders on the same engine frames. The rate of combustion is, however, less rapid with these than with other gases due to the large amount of inert gases such as nitrogen and carbon dioxide present in the mixture. The compression may also be carried much higher without risk of pre-ignition, or "back firing," thus increasing the efficiency of the cycle. With water gas the high percentage of hydrogen occasions quicker combustion and higher flame temperatures with so considerable a tendency to pre-ignition and back firing that this gas is not well adapted to gas engine work.

In water-gas plants a great saving may be made and the gas rendered much more suitable for the operation of gas engines by providing additional holders for the air or blast gas made during the period when the producers are under blast. This gas is equivalent in calorific value to blast furnace gas—90 B.T.U.—and is generally allowed to go to waste. It may, however, be used to great advantage for power purposes, either alone or mixed with a proportion of water gas which it renders less snappy and thereby better suited for use in gas engines. In fact, by this means a gas is obtained similar in many respects to the producer gases made by operating a producer continuously with combined steam and air blasts.

Leaving out of consideration the by-product, or waste coke-oven and blast-furnace gases, as occupying a field of power development somewhat foreign to the subject in hand, producer gas offers at present the greatest possibilities in the field of power for use in manufacturing centres. This is due to its comparative cheapness, simplicity of installation and general efficiency when gas for power purposes is alone considered.

A comparison of the approximate thermal efficiencies of the various processes gives the following results.

Coal gas (without coke)	24%
Coal gas (with coke)	60%
Water gas	60%
Water gas, special quick blast	75 to 80%
Producer gas	80 to 85%

Assuming the calorific value of coal as 14,000 B.T.U. per lb. and the efficiency of the gas-making process 80 per cent., the heat available at the engine is 11,250 B.T.U., which is equivalent to about one bhp. This duty, one bhp per lb. of coal, should therefore be expected from a well-equipped gas-power plant.

The average gas consumption of the stations reported was 39 cu. ft. per kw-hour. In some cases the averages were given for several months' operation, so that the results represent the efficiency of the entire station, day in and day out, with various generating outfits running at varying load factors, and including errors of measurements encountered in every-day operation. Although in some cases "over-dynamoed," the engines are generally underloaded and frequently so much so that good economy could hardly be expected. The average gas consumption per kw-hour is 39.0 cu. ft. Assuming an average calorific value of 625 B.T.U. per ft. for coal gas, water gas, or mixed gas, the heat consumption is 24,000 B.T.U. per kw-hour, 18,200 B.T.U. per electric hp-hour, and 14,500 B.T.U. per brake hp-hour. The average cost of gas charged to the engine is 33.9 cent per M, which is in nearly all cases considerably above the cost in the holder to companies operating both plants, with the result that the gas works realizes a handsome profit from the electric station in addition to the decrease in cost per unit with increased production. This point will be brought out later. Assuming an average production cost of 20 cents per M, the average cost of power is 0.83 cents per kw-hour, equivalent to .0495 cents per brake hp-hour at 80 per cent. combined efficiency.

The comparative cost of steam with gas power is illustrated in two tables. In one two independent stations were operated during 1902, together with the gas works. The cost of coal in the steam plant was 1.38 cents per kw-hour against 0.75 cents per kw-hour in the gas plant, representing a saving of 45.5 per cent., although the cost per M B.T.U. of gas was 3.4 times that per M. B.T.U. of coal. Assuming calorific values of 14,000 and 625 B.T.U. per lb. and cu. ft. respectively, 92,000 B.T.U. were required per kw-hour in the steam station, against 29,100 in the gas station, or a saving in the latter of 68½ per cent. of the former.

In the other table the output was not measured, but the costs indicate the general balance of economy on the side of the gas station. The steam plant started operation on natural gas at 10 cents per M with a minimum of $3,000 per year. It employed boilers fired by gas. One year after starting the gas plant, this minimum was reached and the company is now paying at the rate of over 16 cents per M ft. The saving in total operating cost amounted to 405 per cent. In the face of a 30 per cent. increase in station output, the gas consumption has been reduced by 93 per cent. Previous to the replacement of the steam equipment an economy test was run on the station, throughout 24 hours. The gas consumption at the boilers was 51.09 cu. ft. per ihp, developed at the engines, equivalent to about 86 cu. ft. per kw-hour. All engines were of the simple, high speed type running non-condensing. During the six months ending August, 1902, the total gas consumption of the station, including heating, was 23.8 cu. ft. per kw-hour. Deducting approximately 7.5 per cent. for heating, the net consumption was 21.5 cu. ft., which is about 24 per cent. of that recorded on the steam station. It is equivalent to 12 cu. ft. per brake hp. or a duty of 14,100 B.T.U. per brake hp.

The gross station economy in the case of one plant is shown on curve sheet No. 1. These observations were taken when the station was first started and operating under an extremely low load-factor.. Curve sheet No. 2 shows similar results from another station, which also operates considerably under rating. Both sheets show the decrease in cost of gas at the gas works, due to the increase in works output, necessitated by the electric station. The results may be considered as representative of conditions about as unfavorable to high economy in the prime mover as is usually encountered. Another table gives the operating cost of a plant for six months, during 1902. The average cost of gas is 1.22 cents per kw-hour, and the total operating cost 3.18 cents per kw-hour. Considering this to be a plant of but 135 hp, these results are good.

The above data show in a general way the results that may be accomplished by gas-power plants, even though running under a burden of expense for fuel that would be quite out of the reach of steam plants. It goes without saying that much better results are obtainable in a plant of considerable size of modern design and furnished with reasonably cheap fuel gas

Combined Gas and Electric Stations.—The theory of increase of profits from the operation of combined gas and electric plants is based upon the fundamental principle of reduction in cost per unit with increased output. If the net saving is sufficient to cover fixed charges upon the electric station, the way is clear to reap a double

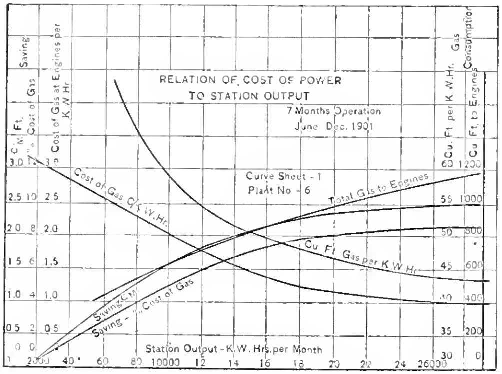

FIG. 2.—RELATION OF COST OF POWER TO OUTPUT.

revenue, one from the electric station operating at a cost far below its steam-driven competitors, and the other from the gas station operating at a lower cost of production than before. The balance may, of course, be applied proportionately to the disbursement of fixed charges on both stations. It is usually the gas station that reaps the profit at the expense of the electric station. An adjustment of gas and electric rates can easily be made to prevent embarrassing competition.

Curve sheet No. 3 shows the cost of coal gas, water gas and mixed gas for approximately 500 gas plants in the United States, from the report o fthe Commission of Labor on Gas and Electric Plants, 1899.

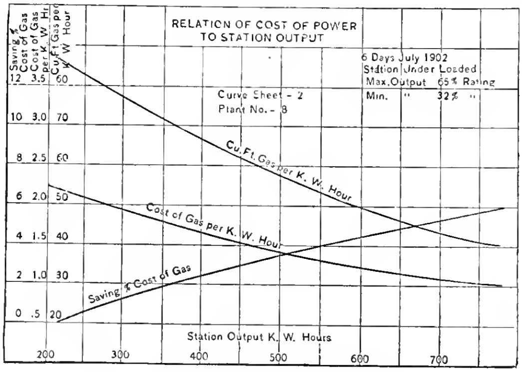

FIG. 3.—RELATION OF COST OF POWER TO OUTPUT.

The curves were determined by the method of moments from a "shot-gun" diagram, and bring out the following points:

1. Cost per unit decreases as output increases, most rapidly in coal-gas plants and less rapidly in water-gas plants.

2. Decrease in cost per unit in small plants of two to ten million per year output is very marked, being greatest in water-gas plants and least in mixed-gas plants.

3. The greatest opportunity for increasing revenue from combined gas and electric station appears to be in the case of small coal and water-gas plants under ten million output. The smaller the plant, the greater the profit.

Curve sheets 4 and 5 represent the saving due to increased production, part of which is traceable to the electric plant and part to consumers. In one plant a saving of 24 per cent. was realized, and in

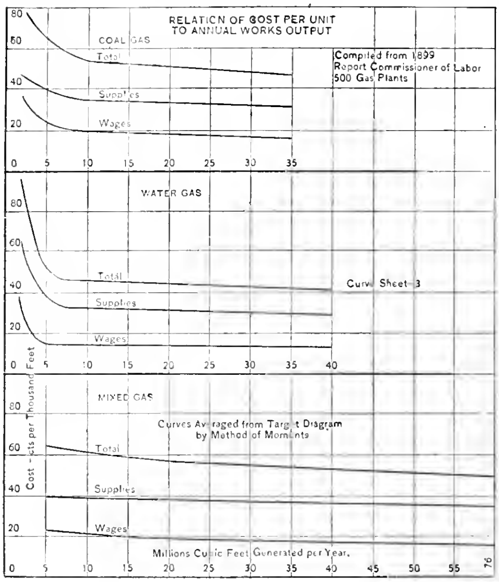

FIG. 4.—RELATION OF COST PER UNIT TO ANNUAL OUTPUT.

still another the remarkable amount of 92 per cent. of initial works cost.

In order to bring out clearly the character of this saving due to increased production, the following case has been estimated along the lines indicated in the preceding paragraph. A ten-million-foot plant has been taken generating gas at 40 cents per M- works cost including coal, bench fuel, labor, repairs, and miscellaneous material, residuals not deducted. Fixed charges have purposely been omitted. The gas is charged at works cost to the electric station. It is assumed that the cost of gas for this plant, previous to absorption of the electric plant, was 50 cents per M, and that the electric plant gen-

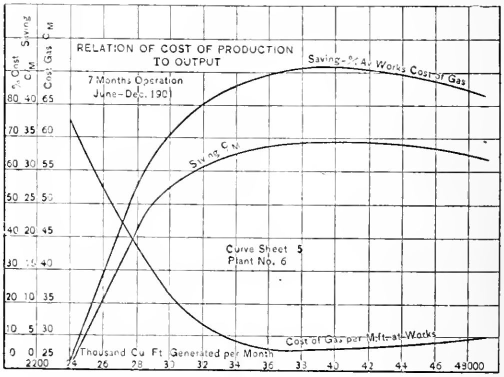

FIG. 5.—RELATION OF COST OF PRODUCTION TO OUTPUT.

erates electricity at twice the fuel cost, 3.2 cents per kw-hour. During normal operation with an output to the electric plant of 30 per cent. of the total amount of gas generated, the total net revenue of the combined works was about $13,300; 45 per cent. of which was due to the electric station and 55 per cent. to the gas station. The operating costs will then amount to 46.4 per cent. of the net revenue.

The comparative market prices for fuel in the case of ten of the above plants averaged $3.63 and $5.10 f. o. b. works for coal and coke respectively, under normal conditions. The corresponding prices during 1902 averaged $4.50 for coal and $7.41 for coke, or an increase of $0.87 and $2.41 over normal for coal and coke respectively.

Comparing the operations of the gas station *per se*, previous to and following the acquisition of the electric station, there is a net revenue of $5,835 and $7,344 respectively, or an increase of $1,509; 25.8 per cent. of the original revenue. Figuring in the saving of 10 cents per M, due to increased production, the total increase amounts to 43 per cent. of the net revenue upon the original gas station.

Considering, finally, the combined works, the increase is $7,449, or 127 per cent. of the original revenue, and adding again the saving 10 cents per M, the total increase is 145 per cent. of the revenue of the original gas works.

Although these percentages will be considerably reduced by the consideration of investment charges, depreciation, sinking fund, etc., the fact remains that the saving due to combined operation is material and should appeal particularly to companies operating independent gas and electric generating stations.

The paper includes an elaborate estimate of the operating cost of a typical gas-electric works having a yearly output of 10,000,000 cubic feet of gas, and supplying customers at $1.25 per 1,000 cu. ft. for gas, and selling current at an average rate of 12 cents per kw-hour. This is followed by ten tables, as follows: Tables giving the data of 15 gas engine electrical generating plants and the cost of operation of eleven of these; comparative operating economy of a 1,250-kw. steam and 685-hp gas engine station; comparative cost of operating steam and gas engine stations on natural gas; operating cost of a 5,000-kw. gas engine station; details of profit from combined operation of a gas engine station and gas works; reduction in cost per unit with increase of production; comparative cost of gas as affected by production; full costs and prices paid for residuals; gas works yields.

A lengthy discussion followed the reading of Mr. Bibbins' paper. Mr. Mershon said that if the paper was intended as a comparison between gas and steam plants, he thought some figures should be given for gas engine installations in connection with gas producers, in comparison with figures for steam plants, taking into account not only economy of fuel but the other charges that should be made, such as deterioration, repairs and interest on investment. He considered that if this had been done the figures would not be so highly in favor of the gas engine, although he was thoroughly a friend of the gas engine, and believed the time was not far off when gas engines and gas producers would be installed instead of steam engines and steam boilers, which state of affairs has already arrived in some other countries. In Germany a great many gas engine plants, including producers, have been installed instead of steam engines, but thus far confined mainly to small plants. In some of these plants an interesting type of producer is used, which is operated on what is known as the "suction principle," the gas engine drawing its charge through the producer; the air in passing through the hot fuel forms a gas, and thus gas is generated only as fast as the engine requires it. Mr. Mershon said that he has seen a number of these plants operating very successfully. The police regulations in some cities do not allow the operation of ordinary gas engine plants, but allowed the installation of the type referred to for the reason that the pressure in the generator and pipe system is lower than on the outside, and there is thus no chance for the leakage of gas. He criticised the statement that the cost of a producer gas engine plant of 1,000 hp is about the same as that of a steam plant of the same size, stating that the cost of the gas plant is considerably above that of the steam plant, and when compared with the steam turbine plant the disparity is much greater. He also disagreed that the cost of operation and maintenance of gas engines is less than of steam engines; from some observations he had been able to make, the cost of maintenance of gas engines is higher. As regards the cost of operation, the gas engine requires a better class of operating attendants than the steam engine. Referring to the table of the calorific value per cubic foot of explosive material, Mr. Mershon said that in European practice the calorific power of the various mixtures employed in the gas engine cylinder is much more equal than shown in the table. In conclusion, Mr. Mershon said that the prices now asked by American manufacturers for large gas engine units are out of all reason as compared with the corresponding price of steam engines, and as compared with European prices.

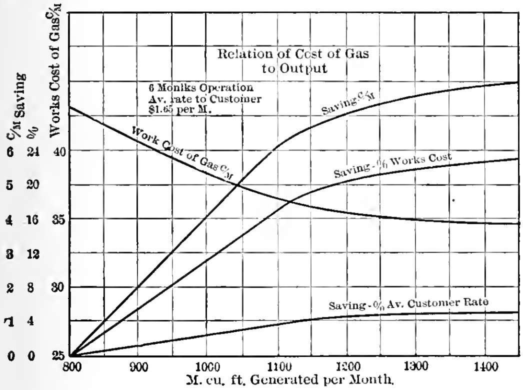

FIG. 6.—RELATION OF COST OF GAS TO OUTPUT.

Mr. Bibbins, in replying to Mr. Mershon, said that fixed charges were excluded for the reason that the idea of the paper was simply to bring out the decreased cost of gas to the gas station due to increased production. He said that he had just been informed by a prominent gas engineer that the comparative cost of gas and steam plants with a fair amount of holder capacity, for the former is about as $125 to $100. Plants on the general suction principle not provided with holders involve the risk of gas of non-uniform quantity in the cylinders. It has been noticed that while at the start quite an intelligent class of attendants is necessary for a gas engine plant, after it has been in operation for some time this does not hold. In the plants referred to in the report the steam engineers have been retained. Mr. H. A. Wagner said that it had recently been his sad duty to replace with a steam plant a gas-engine plant which had been operated for several years by a gas company. There had been three 100-hp alternating units, and the cost of operation became so excessive and increased so greatly from year to year that the gas engine was abandoned in favor of the steam engine. During the last year of operation of the gas engine the cost of producing current was something over 8 cents per kw-hour. The largest single item was that of repairs and maintenance. The engines, however, were not of the latest type manufactured, and doubtless the more modern engines would do much better even after having been operated some years. The experience of this company, however, shows that it is even now a question with gas companies whether it is more economical to install gas engine plants or steam plants. The company in question was using water gas largely and consequently it was necessary to provide a separate producer plants for the gas engines.

In reply to a question concerning the operation in parallel of gas engine driven generators, Mr. Bibbins said that the spring coupling seems to solve the problem to some extent. By means of flywheels of moderate size and spring couplings, generators in each of the three large plants considered in his paper have been able to run under all kinds of load, fluctuating as well as steady loads. The largest of the three plants operates cranes and shop motors, and though the load fluctuates within 100 per cent. almost instantaneously, no difficulty seems to have arisen in operating in parallel.

International Electrical Congress at St. Louis.

We are informed that the State Department at Washington, in response to solicitation from the Director of Congresses at St. Louis, and the President of the American Institute of Electrical Engineers, as well as the Committee of Organization of the Congress, has issued instructions, on December 17, to the American diplomatic officers abroad that they shall invite the various foreign governments to appoint official delegates to the International Electrical Congress of St. Louis in September, 1904. The number of delegates requested to be appointed by each country is in conformity with the precedents established at the Chicago Congress of 1893 and at the Paris Congress of 1900.

Against Municipal Plant.

A special committee of the Common Council of Binghamton, N. Y., has reported adversely on the question of a municipal electric light plant. It is admitted among other things that the item of labor would cost the city 25 per cent. more than it does the present company. The price for lights to the city is $83.95, or $0.021 per lamp per hour, equal to or better than any municipal plant is doing on corresponding terms.

Telephone Transmitters.—IV.

By Arthur V. Abbott, C.E.

The Intensifying Transmitter.—This model is shown assembled, with the cover removed, in Fig. 24; in Fig. 25 the instrument is entirely dissected, excepting the capsule, while in Fig. 26 the parts of the capsule are shown. The foundation of the instrument is a heavy cast brass plate 3¼ in. over all. The diaphragm is of polished aluminum 2½ in. in diameter and .021 in. thick. The rubber strap

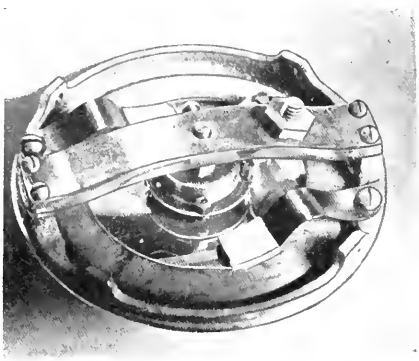

FIG. 24.—INTENSIFYING TRANSMITTER.

which forms a cushion for the diaphragm is 2½ in. long x ¾ in. wide. The bridge is a piece of wrought brass ½ x ⅛ in. thick and secured to the case by four screws. The springs are clock springs .01 in. thick, 5/16 in. wide and 2½ in. long, and bent at right angles. Each spring is tipped with rubber. One spring bears upon the rubber

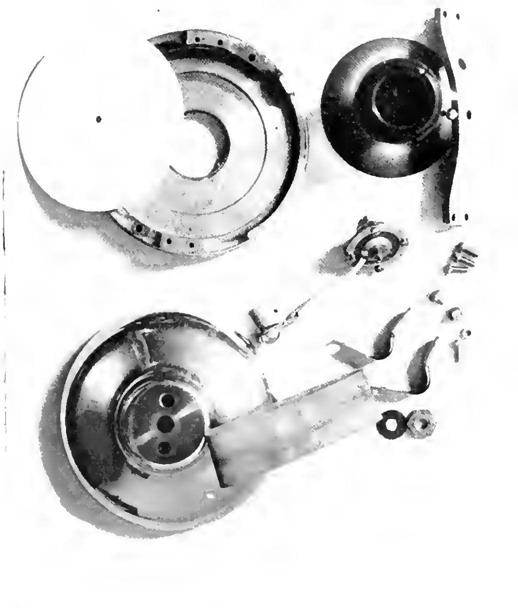

FIG. 25.—INTENSIFYING TRANSMITTER DISSECTED.

strap surrounding the diaphragm, while the other is placed half way between the diaphragm and the capsule. The capsule consists of a spun brass cup ⅜ in. in diameter inside, 3/16 in. deep and .015 in. thick. In the bottom of this capsule the rear electrode is placed, which is ⅝ in. in diameter and is soldered to a brass support that extends to the bridge. The front electrode is also of carbon ⅜ in. in diameter. Each electrode, including the brass supports, is .067 in. thick, giving a space of .07 of an in. between the faces of the electrodes. The front electrode is placed in the center of a mica disc ⅞ in. in diameter, .003 of an in. thick. This disc, as is shown in Fig. 24, is secured to the face of the cup by means of four screws

FIG. 26.—PARTS OF TRANSMITTER CAPSULE.

and a brass ring. The cup is filled with 8 grains of granular carbon. One electrode is connected to the case of the instrument, while the other runs to an insulating binding post upon the bridge and thence by means of a rubber-covered wire to the brass washer that clamps the mica diaphragm.

The Transmitter of the Western Electric Supply Company.—The rear cap of this model is shown removed in Fig. 27, while the instrument is dissected in Fig. 28. There is the usual cast face plate 3¼ in. in diameter over all. The diaphragm is rough aluminum 2½ in. in diameter by .023 in. in thickness. The bridge is 15/16 in. wide and ⅛ of an in. in thickness. It is surmounted in the center by a substantial block of hard rubber 5/16 in. thick, ¾ in. wide and 1⅜

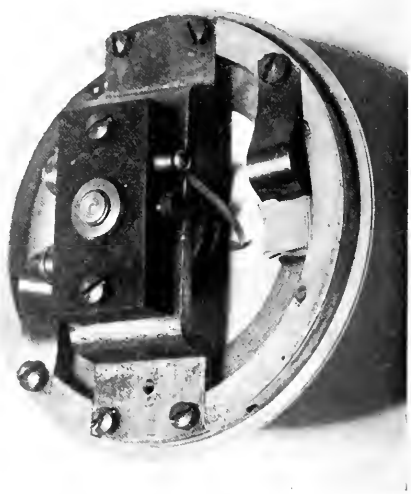

FIG. 27.—WESTERN ELECTRIC SUPPLY TRANSMITTER.

in. long. In the center of this block is a brass bushing which supports the capsule. The leading-in wires run to the rubber block and are thus connected respectively to the front and rear electrodes. The capsule consists of a brass ring 11/16 in. in diameter and ⅜ in. deep. Upon each side of this ring two mica washers are placed ⅞

FIG. 28.—WESTERN ELECTRIC SUPPLY CO TRANSMITTER DISSECTED.

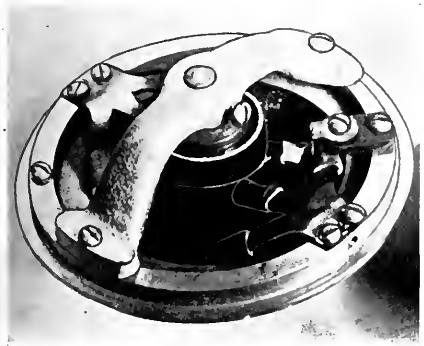

FIG. 29.—CENTURY TRANSMITTER.

FIG. 30.—CENTURY TRANSMITTER DISSECTED.

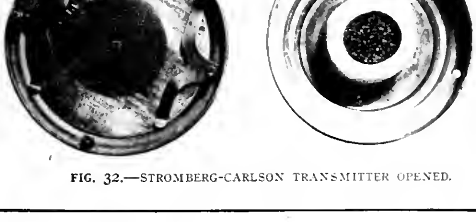

FIG. 32.—STROMBERG-CARLSON TRANSMITTER OPENED.

FIG. 33.—SWEDISH-AMERICAN TRANSMITTER DISSECTED.

TELEPHONE TRANSMITTERS.

in. in diameter and .005 of an in. thick. The electrodes of carbon are each ½ in. in diameter and clamped to its respective mica disc. The discs are then placed upon the ring and over each mica disc another brass ring is fitted and secured by means of four small ears, which are pinched underneath a ledge upon the center ring. Thus, in this model the front electrode can move to and fro with the diaphragm and also the entire capsule is movable through the elasticity of the mica washer that is supported on the rear electrode.

The Century Transmitter.—The transmitter manufactured by the Century Telephone Construction Company resembles in some respects that made by the Western Electric Supply Company. The Century transmitter, however, differs in having its diaphragm made of iron 2½ in. in diameter and .018 thick covered with varnish to prevent rusting. There are two carbon electrodes each ½ in. in diameter, the rear one screwed to a bridge made of cast brass. In Fig. 29 the Century transmitter with the rear cover removed is shown, while in Fig. 30 it is dissected entirely. The capsule is made of a piece of very thin rubber tube, about ⅞ of an in. in diameter and 5/32 in. long. It contains a piece of felt to which two mica discs are cemented. Each carbon electrode is supported by a disc of brass about ⅛ of an in. greater in diameter than the electrode, and after the capsule is filled with 10 grains of granulated carbon the mica washers are cemented to the felt ring, thus

FIG. 34.—SWEDISH-AMERICAN TRANSMITTER, CAP REMOVED.

retaining the capsule in position. In this instrument both the front electrode and the entire capsule can move with the vibration of the diaphragm, but here all comparison of the previously-mentioned transmitter ceases. To check undesirable vibrations of the diaphragm the Century transmitter provides two thin pronged iron springs, as shown in Fig. 30. Each of these is secured to the edge of the face plate by means by two screws, as is shown in Fig. 29.

The Stromberg-Carlson Transmitter.—The first of the so-called "Cornplaster" type transmitters, and one of the widest known models is that manufactured by the Stromberg-Carlson Company, as shown in elevation in Fig. 31, and opened in Fig. 32. This transmitter differs materially from general designs, so far illustrated. It is much smaller and lighter, for the case consists merely of two pieces of pressed brass. The diaphragm is of tin and is secured in the front half of the case by two springs, as shown in Fig. 32. In the center of the diaphragm a piece of wire gauze, which has been gold-plated, is placed, and serves as the front electrode. Upon the rear half of the case there is another piece of gold-plated gauze, forming the rear electrode. Between these two there is a round felt ring which is about two-thirds filled with granular carbon. When the ring is in place the two halves of the transmitter are put together and riveted, so that it is impossible to open the instrument without mutilating it.

The Swedish-American Transmitter.—The transmitter manufactured by the Swedish-American Telephone Company is shown assembled at *A* in Fig. 21. In the bottom of the casting, supporting the transmitter arm, the induction coil for local battery instruments is placed, the terminals of which may be seen in the illustration. Fig. 34 shows this transmitter with the rear cap removed, and in Fig. 33 it is dissected. The face plate is of cast brass, 3⅛ in. in diameter. The bridge is peculiar in that it is a substantial piece of sheet brass, formed in a die, as shown in Fig. 34, thus obtaining one of the stiffest and at the same time one of the lightest designs. There are two springs that are screwed to the bridge piece directly, each of which has two points; thus there are four points of spring contact on the diaphragm to check undesirable vibrations. The capsule is made of two pieces, one being a pressed brass cup, into which a grooved ring, carrying the front electrode, is placed and secured by four screws. The rear electrodes are ¾ of an in. in diameter and the front ⅝ of an in. and the cup is filled with 10 grains coarse granular carbon.

New Telephone Patents.

NOVEL JACK AND PLUG CONSTRUCTION.

Two patents have just been issued for rather novel constructions of jack designed to permit of greater facility of repair than common. In the making of connections both jack and plug are subjected to rubbing and consequent wear, and experience has shown that both must be in time replaced. This is an easy matter with plugs, which are always accessible. With jacks, however, it is an entirely different matter and therefore anything which can extend their life is of value.

Mr. C. M. Hedman, of Chicago, to whom the first of the patents under consideration has been issued, has applied to jacks a removable test ring. This threads into the hard rubber face strip of the jack strip, the end of the corresponding contact spring being expanded into a ring within the face strip drilling to form a stop for the test ring. Whenever a test ring wears out, of course, its replacement by a new one is but a matter of a few moments.

In the second patent, granted to Mr. W. W. Dean, of Chicago, the overcoming of the wear of the jack springs is chiefly considered, the wear being largely transferred to the plugs. This necessitates such a novel type of jack and plug that a clear understanding is best obtained by reference to a drawing of them (Fig. 1). As will be seen,

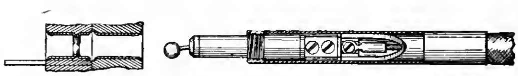

FIG. 1.—DEAN TERMINAL AND PLUG.

the jack consists of two concentric tubes, one behind the other. The forward one, which engages the plug shank, has a smooth bore and flared front as is customary, while the rearward one carries an internal ridge about midway its length. The plug tip is flexibly mounted upon the end of a spring member, and stands normally somewhat off centre. When the plug is inserted, the ridge of the jack engages the plug tip to hold the plug in place. The result of this design is at once evident, for while ordinarily the wear of the jack spring is confined to a single element of its length while that of the plug is distributed over its whole periphery, now the plug wear comes upon a single element and the jack wear is distributed over its whole surface. The Stromberg-Carlson Company has obtained the first of these patents, while the latter has been assigned to the Kellogg Switchboard & Supply Company.

CONNECTION COUNTER.

A connection counter for use where measured service is the custom is the subject of a patent issued to F. R. McBerty, of Chicago. This counter is so designed and so connected to the circuits that it registers one message for each completed connection, and yet fails to register any other manipulation of the line. The counter is so designed and connected to the circuit that it is ready for operation at all times, except during a conversation. At this time it is locked. In other words, the counter responds only to the removal of the receiver from the hook at the answering station, and having once responded it so transfers its own connections as to lock itself against further scoring until after this connection has been taken down. Mr. McBerty has assigned his patent to the Western Electric Company.

BALANCING TRUNKS FOR DUPLEXING.

Of late considerable work has been done toward the use of duplex or phantom circuit working over trunk lines. The chief obstacle in the way of successful working in this way is the difficulty of securing and maintaining the necessary accurate balance of the trunk line to avoid interference. To overcome this difficulty Mr. H. O. Pugh, of Chicago, suggests the extension of the trunk line from the main jacks to an adjustable rheostat, through the arm of which the second circuit, which is to use this trunk, is connected. The operator is supposed then to adjust the rheostat cutting resistance from one side of the top to the other until a condition of non-interference exists. The Illinois Electric Specialty Company has obtained the patent for this arrangement, which patent is confined to the simultaneous connection of two grounded and two metallic lines.

IMPROVEMENTS IN CABLES.

A new design of telephone cable has been patented by Francis Tremain, of England, in which the conductors are arranged in a special manner to permit of the use of two pairs to form conductors of lower resistance. The foundation conductors are ordinary twisted-pair insulated conductors; each has a uniform twist in itself, but there is a variation of pitch of twist in different conductors. Four pairs with different pitches are twisted together to form a strand. These four may, of course, be used to form two pairs, which pairs are inductively neutral to each other, and of which each conductor consists of a fundamental pair of conductors. Thus, for long circuits conductors may be used of half the normal resistance. It is, however, difficult to see what advantage such an arrangement has over two twisted pairs taken in parallel, wire and wire, in which latter case irregularity of resistance due to difference in pitch of twist is avoided. Another patent referring to cable construction is that of H. W. Fisher, of Pittsburg. This relates to a method of wrapping paper insulation about the wires for telephone cables by which the paper strip is caused to crimp. The result is a bulky insulated conductor, a larger part of the volume of which is air space. Such conductors twisted loosely together form a cable with low electrostatic capacity because of the large proportion of air insulation. This patent has been assigned to the Standard Underground Cable Company, of Pittsburg.

TWO NEW LINE PROTECTORS.

A rather novel open-space lightning protector is that of Charles E. Nicholas, of Columbus, Ohio. This consists of a metallic tube surrounding the conductor to be protected and held concentric therewith by insulated bushings. High-potential charges pass to the tube and are thence conducted to ground. An interesting suggestion is the use of such a device let into the cross-arm and serving as both protector and insulator. Another line protector is that of W. P. Woodruff, of Buffalo, and Daniel J. McCarthy, of Wilkinsburg, Pa. These inventors provide a magazine fuse terminal in which a large number of fuses may be stored. As fast as one operates, the melting fuse permits the spring terminals of the device to release the fuse carrier, when a fresh fuse is immediately provided from the magazine. The utility of such a device is questionable. With a considerable capacity to the magazine and a bad heavy current cross it would seem that all the fuses will be quickly blown, even if it can under any circumstances be considered good practice to continually re-fuse a line in trouble without ascertaining that trouble.

BATTERY TRANSMITTER.

Under the above title John S. Golberg, of Chicago, has patented the transmitter shown in section in Fig. 2. The most novel feature

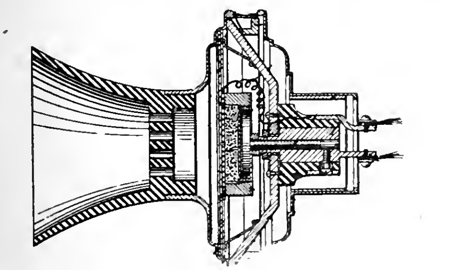

FIG. 2.—GOLDBERG TRANSMITTER.

consists of two spring spiders, one to hold the diaphragm and the second to give an added flexibility to the carbon chamber. The diaphragm spider is shown in section and appears as a truncated cone. This cone shape makes it virtually self-centering. Arising from each leg is a sheet spring finger which engages the diaphragm. The second spider, also of sheet spring metal, is clamped to the rear electrode in a manner such that the ends of the legs bear upon the rim of the granule box. The packing about the rear electrode is felt, which is alone less satisfactory in permitting free motion of the electrodes than when supplemented by the spring spider. The Stromberg-Carlson Company is the assignee of this transmitter.

AUTOMATIC EXCHANGE.

A patent has been recently granted to F. A. Sundquist, of Chicago, for an automatic telephone exchange which is in the nature of an improvement on a system previously patented by him. The switchboard is designed for large systems involving auxiliary switching processes. All parts seem to be well worked out, and the circuits and apparatus comparatively simple. This system has the merit that the work required of subscribers is of a simple nature, and it seems to compare well with existing apparently successful systems.

TELEPHONE WALL SET.

A new arrangement of apparatus box for telephone wall sets is the subject of a patent issued to E. B. Fahnestock, of New York. The novelty lies in an arrangement of the hinge of the swinging front such as to permit of the condenser of the set being slipped out of the box between the cover and the back board through the hinge opening.

The Design of Motor Starting Rheostats.

By ARTHUR H. FORD, E.E.

THE writer has frequently had trouble with motor-starters due to the rush of current, when the final resistance was cut out, being so great as to throw the circuit-breaker or blow the fuse used to protect the motor. An investigation has shown that this is a defect of nearly all motor-starters. Under the usual conditions, when the motor is started light, this is not noticed; but if the motor is required to start a load requiring nearly its full load torque, the shock to the belting and motor is serious, to say nothing of the annoyance of being obliged to set the circuit-breaker or replace the fuse frequently. In many cases the person who starts the motor makes a practice of holding the breaker in, if it is within reach, or tying it fast if it is not. These facts led to an investigation of the problem which resulted in the general solution given below.

The solution is given for a shunt motor on a constant-pressure circuit of unlimited capacity; but is equally applicable to a series or compound motor, provided that the motor resistance is high in comparison with the resistance of the generator and line. When power is first turned on there is a rush of current through the machine determined by the pressure of the circuit and the combined resistance of the rheostat, armature and connections. The armature now begins to revolve at an increasing speed, having for its limit that speed at which the counter e.m.f. required to keep the current down to the value which gives the necessary torque, is generated. If, when this state is reached, one section of the rheostat is cut out, there will be a sudden increase in the current, which will have the same value as if an e.m.f., equal to the fall of potential over the section cut-out, had been introduced into the circuit and its resistance reduced by an amount equal to that of the section cut out. This cycle of action is repeated each time that a section of the rheostat is cut out. In order to get the motor up to speed as soon as possible, the sudden rush of current should be the same for each section of the rheostat cut out and should be as large as safety will permit. This will give a current through the armature which will vary from a maximum to a minimum, successive values of which will be the same, provided the torque is constant or a section is cut out of the rheostat each time the current falls to a given value.

Let n = the number of divisions of the rheostat.
R_a = the resistance of the armature and connections.
R_m = the resistance of any rheostat section.
I = the minimum current through the armature during the starting period.
$I(1 + a)$ = the maximum current through the armature during the starting period.
E = the line pressure.

Under the conditions just stated,

$$Ia = \frac{I\,R_n}{R_a + R_1 + R_2 + R_3 + R_4 \,\ldots\ldots + R_{(n-1)}} =$$

$$\frac{I\,R_{(n-1)}}{R_a + R_1 + R_2 + R_3 + \ldots + R_{(n-2)}} =$$

$$\frac{I\,R_2}{R_a + R_1} = \frac{I\,R_1}{R_a}$$

from which $R_1 = a\,R_a$

$R_2 = a\,(R_a + R_1)$

$R_n = a\,(R_a + R_1 + R_2 \ldots + R_{(n-1)})$,

giving as the general expression for the resistance of any rheostat section,

$$R_m = a\,R_a\,(1 + a)^{m-1} \qquad (a)$$

When current is first turned on,

$E = I\,(1 + a)\,(R_a + R_1 + R_2 + R_3 + \ldots + R_{n-1} + R_n)$

from which $E = I\,R_a\,(1 + a)^{n+1}$ (b)

Equations (a) and (b) enable one to calculate the number of steps and the resistance of each, provided that the starting conditions, resistance of armature and connections, and line pressure are known.

An application of this method to various machines (assuming Ra to be twice the armature resistance, I the full-load current, and a to be .5) shows that starting rheostats should have about nine sections.

The Adoption of Direct Current Traction on the New York Central Railroad System.

Considerable space has recently been given in these pages to the eventful and historical determination of the New York Central Railroad to adopt electricity for the operation of virtually the whole of its train service at the New York terminal and within a circle whose radii extend at least 35 miles out from the Grand Central Depot. This decision by one of the oldest and greatest of the steam railroad systems in the United States has naturally attracted attention everywhere and aroused the most profound interest. The action of the New York Central Railroad Company in adopting the report in favor of electricity from its commission organized under Vice-President Wilgus to investigate the subject, is one fraught with such momentous consequences alike to the public and to the engineering profession and industries that even the slightest light which can be thrown upon it is of value. In fact, it would be difficult to overestimate the importance of the event, which easily takes its place as the most significant in the history of electrical engineering in 1903.

The readers of ELECTRICAL WORLD AND ENGINEER will remember that the contracts given out by the New York Central Railroad Company embodied two startling innovations and one not less interesting evidence of conservatism. In the first place it has been decided to operate the generating plant by steam turbines, and in the second place it has been decided to operate a very large part of the traffic, namely, that embracing all through trains, with electric locomotives of not less than 2,250 hp each. Striking as the boldness is in these two developments, it is considered by some engineers as offset by remarkable prudence amounting even to conservative timidity in adhering to the direct-current method instead of pushing boldly forward and adopting at once alternating-current apparatus. Under the circumstances we have deemed it desirable to ascertain if possible what the reasons may have been for adopting the direct current in the New York City zone. Neither the railroad company nor its commission has hitherto been willing to give out any official statement upon this interesting subject, but we believe we are justified in submitting below a brief summary of what may be accepted authoritatively as the considerations which led directly to their action. The result of our inquiries on the subject is such as to throw a flood of interesting light upon a great many new points, although it is possible that in some respects we do not fully appreciate or adequately present the force of all the arguments which have compelled resort to direct current at the present time.

The reasons for the action of this great corporation, it would appear, may be divided into two classes, namely, those of policy and those of engineering technique. The word policy in this respect is one of large meaning, but the idea is that the system adopted should leave the widest latitude for the possible future interchange of equipment with other analogous local systems. The New York Central Railroad in determining to minimize as much as possible the inconveniences to the public in this work, has at once realized that as other rapid transit lines in this city are and will be equipped with direct-current motors, its work must be in harmony with theirs. The adoption of the direct-current system, therefore, while leaving optional the selection of the best method of the future handling of the transportation service would facilitate rather than hinder changes which would have now to follow the change in operation and in financial conditions. On the other hand, the employment of the alternating-current system, individual and unique so far as the New York Central road is concerned and not corresponding with the local systems into which it must inevitably interweave itself, would prevent such harmonious action. At a time of extraordinary transition in all the transportation arrangements of New York City, it would have been in all probability a serious and an irreparable error for the New York Central Railroad to have adopted that which is not only newest in the art, but unrelated to that which is already standard and in use in and around New York City. We have ourselves no knowledge or intimation as to the plans and ambitions of the New York Central officials as to the local systems, but such reasons of policy as we have hinted at can certainly be postulated as amongst the prior considerations on the subject governing their action.

With regard to the technical reasons, we have, as our readers are well aware, presented recently in these columns, a vast amount of matter with regard to the advantages of the alternating-current method of traction, and have set forth in great detail the single-phase work of such leaders in this field as Arnold, Lamme, Finzi, Winter-Eichberg, Ward Leonard and others. In view of so much work of promise for the future and of such an elaborate presentation of the alternating-current arguments, we have been particularly anxious to ascertain the technical reasons why the direct-current system appears to the experts and the commission entrusted with the subject to have determining advantages over the alternating-current system at the present stage of development. We hardly know whether the matter of cost should be considered a technical one or not. At this stage of development between the two systems it has undoubtedly been one with serious effect on the matter. The board under Mr. Wilgus, it would appear, found that there was a great uncertainty as to the relative costs of the installation of direct current and of alternating-current apparatus, due obviously to the recent rapid development in the art as applied to alternating-current motors. Hence, while one of the bidders had apparently no trouble in showing a considerable difference of cost in favor of direct-current apparatus, another bidder, at the very latest stages of the settlement, brought to notice a type of alternating-current motor, which it was claimed would cost but little more than the direct-current apparatus. Further than this, it would appear to have been claimed that the overhead construction with alternating-current devices could be avoided on the Park Avenue viaduct and tunnel, and this, if true, would remove one of the strongest arguments against the use of the alternating current.

On the other hand, if we assume that a high-potential third rail could not be avoided, but that overhead construction would be necessary on the viaduct and tunnel, and taking into account the differences in the bids, there would seem to be a large difference in cost in favor of the direct-current system. If the figures were available and were before us, we could possibly make a more specific exhibit of the difference in cost referred to. The situation is, therefore, not a little complicated by the pros and cons in respect to cost, but it would seem that the very points thus alluded to have played their part in bringing about the decision in favor of the direct current. It can readily be understood that a great many features of objection in the minds of the railroad company would attend the use of the overhead construction of bare wire with the alternating-current system, including the liability of injury to trainmen as well as the tendency to corrosion of wires from the gases of freight steam locomotives. There are also obvious dangers and difficulties in lowering the four tracks of the Park Avenue tunnel under the existing enormous traffic, and a great many legal uncertainties crop up in connection with the construction of an overhead system on the Park Avenue viaduct. Admitting that the overhead construction could be avoided on the viaduct and in the tunnel, the difference in cost, if we understand the facts aright, would undoubtedly have been in-favor of the alternating-current apparatus, but viewed broadly and all things considered, the arguments for the direct-current system have prevailed, being supplemented by others of equal moment to which we shall now refer.

Amongst the points which we have elicited is one to the effect that the alternating-current locomotive would have a greater weight, thus adding from 7 to 10 per cent. to the train weight, with a consequent increased cost of transmission, installation and operation of the power plants, which would more than offset the economy due to the use of static transformers instead of rotary converters. Further than this, the alternating-current apparatus for both motor cars and locomotives would involve greater cost of maintenance.

The next point would appear to involve the greater depreciation in value of the alternating-current type of apparatus, and due to the curious fact that being now novel and more or less untried it would inevitably soon have to be discarded and scrapped to make room for improved types in the near future, whereas direct-current apparatus being standardized and universal in application, would prove a good asset with a high percentage of salvage whenever a change to alternating current might prove itself to be necessary. Over and above these leading considerations, others involved are the present imperfect development of alternating-current apparatus when viewed in regard to the complex and important traffic on the New York Central Railroad, which must be handled safely and successfully without any ifs or buts, the paralysis or temporary interruption of such a great national highway being attended with losses to the company and to the public beyond calculation. It is to be remembered, moreover, that the company is required to make a local change within a very short given period of time and without any chance of failure; and this being the case the conviction has been irresistible that direct-current apparatus is at once the safest and the only type to adopt to meet the stringent conditions imposed by the legal, financial, engineering and other broad considerations bearing upon the question.

It is not to be understood for a moment that the alternating aspects of the subject were not fully weighed, and from all we can learn in regard to this matter they were given the most prayerful consideration up to the very latest moment, but even allowing that the alternating-current system under the most favorable circumstances might cost a great deal less than the direct-current system, there remained the other reasons of policy and engineering technique which, so far as the commission and the railroad company were concerned, removed the last shadow of doubt as to the wisdom of adopting direct current within the proposed electrical zone, south of Croton and North White Plains. Going beyond this important and initial zone there would appear to be later on abundant opportunity for resort to the alternating current when its perfection would warrant its adoption for long-distance service. How close at hand this is no one can say. A great deal of the best invention and work of the time points in that direction, but meanwhile it must be felt that the New York Central Railroad Company is to be commended for the high prudence and wisdom which has been associated with its adoption of the most progressive policy seen in the main railroad field for a great many years. In fact, one might well call it the most momentous decision of the kind of the last half century.

Recent Electrochemical Developments.

MANUFACTURING MANURE FROM APATITE.

A patent issued to Mr. Wilhelm Palmaer, of Stockholm, Sweden, relates to a method for making bicalcic phosphate from apatite. In the bicalcic phosphate the phosphoric acid has the same manurial value as the phosphoric acid of superphosphate soluble in water or citrate solution. The process consists of several steps. The first step is the electrolysis of a solution of a suitable salt (chlorate of sodium or periphlorate of sodium), which yields at the anode an acid forming with lime a soluble salt and at the cathode a basic hydrate. The acid obtained at the anode is made to act on mineral phosphate in a separate vessel. To the acid solution of the mineral phosphate thus obtained the alkaline solution formed at the cathode is then added and precipitation of bicalcic phosphate results.

CURRENT NEWS AND NOTES.

WORK WITH RADIUM.—Prof. Roux, of the Pasteur Institute, reported last week some interesting experiments Dr. Danis made with radium. He hung a tube containing the metal above a cage containing mice for fifteen hours. Twenty days afterward the rodents began to lose their fur, which grew again, but of a different color, gray mice becoming white. When the period of exposure was extended the animals succumbed to paralysis, the younger mice being the most quickly affected.

CHICAGO MEETING A. I. E. E.—The coming meeting to be held January 12 is to be one of special interest to central station men, as an opportunity will be afforded for a free discussion of the papers presented at the New York meeting December 18. These will be abstracted briefly and Mr. Lamar Lyndon's paper presented at the previous meeting read at the same time. The committee has received assurance of the attendance of a number of central station men from out of the city.

NEW MULTIPLE VOLTAGE DISTRIBUTION SYSTEM.—A patent has been issued to Mr. George H. Gibson on a multiple voltage generator which allows a large number of voltages to be taken from a single machine. The generator has a double armature winding and the Dobrowolki principle is utilized of producing on a point of the winding of an external inductance an image of the neutral point of an armature winding, to which point a supply neutral conductor is connected. The machine has two commutators—one for each armature winding—and two sets of slip-rings for the neutral connection. The neutral or fifth wire of the distribution circuit is, by means of a special disposition described, made to act as a neutral for both commutator circuits. Assuming that the voltage at one commutator is 50, and at the other 200, voltages of 25, 50, 75, 125 and 200 are available on the distribution circuit.

ANNUAL DINNER OF THE BRITISH INSTITUTION OF ELECTRICAL ENGINEERS.—The British Institution of Electrical Engineers held its fifteenth annual dinner at the Hotel Cecil December 9, with a large number of distinguished guests present. Among these were Prof. E. Hospitalier, president of the Société Internationale des Electriciens; Sir W. H. White, Sir W. Ramsey, Lord Reay, Lord Monkswell (chairman of the London County Council), Lord Biddulph, Lord Claud Hamilton (chairman of the Great Eastern Railway), Hon. A. Brodrick, Sir Norman Lockyer, Prof. S. P. Thompson, Lieut.-Col. Crompton, Sir A. R. Binnie, Prof. W. E. Ayrton, Sir J. Wolfe Barry, Sir W. de W. Abney, Sir G. L. Molesworth, Sir J. F. Bridge, Major-Gen. W. T. Shone, Major-Gen. C. E. Webber, Sir H. Mance, Lieut.-Col. H. A. Yorke, Col. R. M. Ruck, Col. W. Pitt, Mr. R. B. Martin, M.P., Sir C. J. Owens and Mr. James Swinburne. About 500 were seated and one of the English journals ascribes the great success of the occasion to a new feature of the programme, which provided, after the formal ceremonies, a period of informal social intercourse. Lord Monkswell spoke on "The Institution of Electrical Engineers" and Mr. J. Swinburne. Sir C. J. Owens and Sir J. Wolfe Barry on "Railways and Telegraphs." Prof. S. P. Thompson proposed the toast, "Our Guests," compiling with it the names of Prof. Hospitalier, Lord Claud Hamilton and Sir William White. Prof. Hospitalier, on rising, received an enthusiastic welcome which, according to one of the accounts, "was well-nigh endless." He referred with pride to the fact that for 22 years he had been a member of the Institution. Sir William White, in replying, said he did not believe in a hard and fast separation between scientific societies and engineering societies. There was a distinction between pure and applied science, but a man who devoted himself to the application of science was equally as worthy of respect as the pure science man; and in connection with education matters engineers must not permit pure scientists to say what should be the training of the engineer. Sir William White, it may be added, is one of the "old guard" committed against the modern methods of technical education. After the dinner the company adjourned to a hall where members had an opportunity to meet the distinguished guests.

POWER STATION AT CAFFARO.—The numerous water powers found in the Italian Alps are now being used very extensively for developing electric power. One of the largest lighting and power plants is now being built in the Province of Brescia, on the Italio-Austrian boundary, at Caffaro. The station will be equipped with five generator units of 2,500 hp each, all furnished by the Oerlikon Company. The main line to Brescia will be 50 km. long and will carry 40,000 volts. Aside from the Bülach-Oerlikon transmission line, this is probably the only one in Europe transmitting so high a voltage. In connection with this power station, there will be a transformer sub-station of 3,250-hp capacity for operating an electro-chemical factory.

INSTRUMENT DIAL PLATE.—A prolific cause of trouble in indicating electrical instruments is the tendency of the scale to warp and hold the the pointer. To obviate this annoyance Mr. J. Franklin Stevens has devised and patented a method of constructing scales or dial plates which, though simple in detail, is stated to maintain a plate in perfect condition indefinitely, and to completely overcome all tendency of the cardboard to separate from its backing or to warp or blister when subjected to moisture. The method, briefly, consists in perforating the metal plate to which a scale card is secured, thus enabling the cement employed to sink in the perforations and thereby effect a closer union and contact with the metal The plate may be, say, 20 to 25 mils. in thickness, having about 400 perforations per square inch, each about 25 mils. in diameter. A slow-drying cement is used, and a moderate amount of heat is employed while the card and metal backing are subjected to pressure. After all scale divisions are on the card the face is coated with pure white lacquer or similar colorless water-proof substance.

LETTERS TO THE EDITORS.

Motor Drive in Railroad Shops.

To the Editors of Electrical World and Engineer:

SIRS:—I have read with great interest Mr. R. Lozier's very able article in reply to my own, on the subject of machine tool drive, yet I must still adhere to the ideas advanced by me as far as railroad shops, or, in fact, any large shops are concerned, but agree with Mr. Lozier this far that if the shop is small, and the output varied, such an equipment as he describes may justify the increased cost of the multi-voltage system.

In a railroad shop, or in any large shop where there are a large number of tools installed, if the shops are properly laid out, the work will be adapted to the tool, namely, a tool that will do a certain class of work year in and year out. As an illustration, in a railroad shop, an axle lathe will turn axles, a wheel lathe will turn wheels, and so on, and the wheel lathe should not be called upon to do small work. Therefore, the speed at which these machines will run should never vary to any large degree. The maximum speed possible is quickly and easily obtained by the method outlined in my previous article, and a motor ordered for that rate of speed. Now, if there chance to be a few rare cases in which the speed must be varied, the cone pulleys can take care of the change readily, and far more economically than the multi-voltage system, of which the interest on the large initial outlay, goes on year after year, in addition to depreciation. And that the multi-voltage system is costly, no one who has figured on installing it can deny.

Mr. Lozier cites as an instance the finishing up of an armature spider, where the motor is speeded up and slowed down at short intervals. This is very well, but railroad shops do not do this class of work. Still, in a large shop, where this work is done, I see no reason why the work could not be arranged so that each tool could do certain work, and then the spider be passed on to the next tool, if there were many of them to do.

Again, in taking up my ideas on the grouping of tools, with a single motor to a group, at constant speed, Mr. Lozier admits the advantage of a motor without a commutator, but weighs against this the possible factor of wattless current.

Now the factor of wattless current only becomes apparent when the induction motor is underloaded, and it then becomes a mere question of judgment in determining the load factor of your group, and selecting a motor that will be so small as to have an efficient load. If a larger load does happen to come on at rare intervals, it is a well-known fact that the induction motor can take care of overloads with far greater ease than a direct-current motor, can, in fact, be blocked at full current without injury, which cannot be done in the case of the direct current, so this objection then becomes nil.

He also fails to state another factor in the case of the multi-voltage system, namely, the controller required. Now, as regards controllers, reversing the statement of the Irishman about whiskey, "some controllers are better than others, but there are none good," and when you throw this question into the balance, the advantage is altogether in favor of the induction motor, as any one who has had to maintain a large controller equipment can testify.

Again he speaks about the certain amount of direct current necessary for cranes in any case. I may say here, that on future installations projected by me that alternating current will be used throughout, for cranes as well as tools, as the alternating current crane has passed the experimental stage, and become a commercial success, and is as easily operated as a direct-current crane.

One word more and I have finished. Mr. Lozier and others have laid great stress on the fact of the operator being able in the multi-voltage system, to vary the speed of his work at will. Here I must differ from him radically, as I do not think that the operator should be allowed to vary from the instructions given him by his shop superintendent. Were this permitted every man would need to be of such high class and skill, that the cost of production would far outrun the economy gained, or else the amount of work and tools ruined would produce the same result.

In summing up, therefore, I may say that while Mr. Lozier's views are sound and well taken from his point of view I must still adhere to my own, as regards economy of installation, and operation, and I may here quote the saying of a high authority regarding an engineer. He says, "A successful engineer is the one who can make a dollar earn the most money." This saying is most true where large corporations are concerned, and doubly so in the case of small ones.

MONTREAL, CAN. C. H. HINES.

What is Not New in Peat Treatment.

To the Editors of Electrical World and Engineer:

SIRS:—On page 1014 of your December 19 issue I note your remarks in describing the would-be new telephonograph alleged to be just invented in England: "This was all done successfully years ago —let us have something really new." It is a pity you did not put the paragraph relative to the electrical preparation in England of peat, on page 1010, in the same category. The process described therein is identical in all essential respects with that described in the patents of Charon and Oligny issued something like two years ago in the United States. As I had a good deal to do with these patents and the experiments carried on under them at St. Isidore, Quebec, I am thoroughly familiar with the possibilities in this line, and it may as well be stated that, as regards electrical treatment of peat to carbonize it, there is absolutely "nothing in it." In fact, a very easy calculation will show that the mere cost of evaporating the water remaining in peat even after it is dried as thoroughly as possible by presses or centrifugal dryers costs more per ton than the price of coal. It is all very beautiful in theory to "expel all but a small remnant of the 80 per cent. of water" by a centrifugal machine, but anybody who is any way familiar with this class of machine knows that it can't be done. As for "moistening the mass with certain cheap chemicals," this is reminiscent of the "secret liquid" forming so prominent a feature of promoters' schemes, and it is practically safe to say that whether the liquid be cheap or otherwise does not change the character of the proposition.

It must be obvious to every one that the evaporation of water by electrical heat necessarily costs at least ten times as much as by direct heat from the fuel, for the simple reason that only one-tenth, at the maximum, of the heat of the coal is represented in the electric current produced therefrom. Hence it is perfectly obvious that the electrical process cannot compete with the direct process.

As for the alleged superiority of the electrical current in that "it converts but does not destroy any of the valuable elements of the peat, whereas coking by fire heat expels a large percentage of these elements in the form of gases, which being either wasted or burnt as fuel beneath retorts are lost from the composition of the ultimate product"—this is mere "springes to catch woodcocks." When peat is coked by direct heat in suitable retorts the gases expelled are principally water and incombustible gases, and they are utilized as far as possible to coke the peat by burning them (that is, the combustible portion) under the retorts, and are in nowise wasted. As for being valuable elements of the composition, that is nonsense.

Your citation gives the "high thermal value of 9,000 British units" as the result obtained by this alleged new process. As a matter of fact I consider this a very low thermal value, scarcely exceeding that of good hardwood. Ordinary lignite has shown as much. The Canadian briquetted peat already produced, as above alluded to, which I have seen burnt, has given a value of 12,437 B. T. U., as shown by tests of the Quebec Government Assay Laboratory, and but 2.87 per cent. of ash. The cost of producing such peat, not by the electrical, but by other processes tested, was estimated at between $1.50 to $2, and it is perfectly safe to say that this is the very lowest which can be reckoned on anywhere. The cost of producing it in the manner mentioned in your article would actually be found between $6 and $10 per ton instead of $1.21 as given.

Milwaukee, Wis. George W. Colles.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Alternator with Direct Excitation by Alternating Current.—Heyland.—A very long paper illustrated by diagrams, read before the Electrical Society, of Berlin. He describes in detail the principle of his new system of self-excitation and compounding of alternators which has already been noticed several times in the Digest. The first experiments with this type of alternator were made by Kolben & Co., and this firm has already placed a considerable number of machines of this type on the market. The machine is of the construction of an ordinary alternator with stationary armature and revolving field. The essential difference from the ordinary machine is that the exciting current is not supplied from an exciter, but the alternating current generated by the machine itself is, with the aid of a commutator, supplied to a peculiar system of parallel windings around the poles. The principle of the machine is discussed and diagrams are given which represent its behavior. The claims which he makes for this alternator are as follows: Compared with the ordinary alternator his new machine is distinguished by a better utilization of material (less weight of copper and iron per unit of power), by higher efficiency and by a more exact regulation. Since the armature reaction is removed, dimensions may be chosen for the machine which one would obtain with ordinary alternators with high armature reaction. With an ordinary alternator the maximum permitted voltage drop is generally given, and from this result the necessary field strength and the dimensions of the poles and iron cross-sections follow. His type of alternator may be built with a relatively weak field, so that all the dimensions are at once reduced, together with the iron losses, the copper losses and the copper on the poles. The machines have a high efficiency and the efficiency curve is good for all loads, since it increases rapidly for small loads and then remains nearly constant over a wide range of load. Another advantage is the absence of a direct-current exciter. If no exact compounding is required, but only regulation of voltage within the usual limits, the compounding transformer may be omitted altogether and the machine becomes very simple, requiring in operation in parallel no balancing wires or other accessories. The advantage due to the absence of the armature reaction is greatest in machines with few poles and running at a high speed, or in machines for low frequencies. After the paper had been read there was an extended discussion, a full report of which is given. It was brought out there that Heyland uses two transformers, one for compounding and the other for exciting.—*Elek. Zeit.*, December 17.

Commutator.—Mason.—A communication giving instructions for amateurs how to make a commutator.—*Am. Mach.*, December 31.

Lights and Lighting.

Photometric Tests of Nernst Lamps.—Sheppard.—A communication referring to the fact that the candle-power of a Nernst lamp of American make varies very considerably with a small difference in voltage; thus a 1 per cent. variation makes a change of 6.4 per cent. in the candle-power. He considers this to be a characteristic difference with respect to Nernst lamps of German make. The data for the latter are given in Fig. 1, in which the full-line curve refers to the Nernst lamp of German make, while the dotted curve referring to the carbon incandescent lamp is given for comparison. An increase of voltage from 100 to 105 causes an increase of the candle-power by 1.5 per cent., and a drop of the voltage from 100 to 95 reduces the candle-power by 30 per cent. In England Nernst

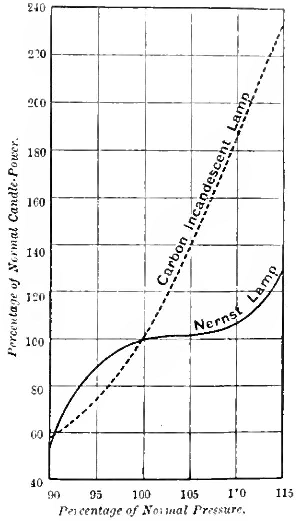

Fig. 1.—Curves of Photometric Tests.

lamps are required to be suitable not merely for the nominal pressure of the supply, but also for the maximum pressure likely to be met with. With the curves he considers that this is sound economy.—Lond. *Elec.*, December 18.

Power.

References.

California and Niagara Power Transmission.—Dunlap.—A comparison. In California widely separated electric systems have been unified into a single and very extended unit of large proportions and great mechanical difficulties had to be overcome. Niagara Falls power is in the midst of a thickly-settled section.—*Westgt. Elec.*, December 19.

Superheated Steam.—Reynolds.—An abstract of a paper read before the Rugby Engineering Society in which the author explains the principal objects of the use of superheated steam and the precautions which must be taken.—Lond. *Elec.*, December 18.

Indicator Diagrams.—Hubbard.—An illustrated article in which the author explains the indicator cards with reference to the internal working of the engine from which they are taken. The author gives cards showing the most common faults in the distribution of steam in the cylinder, such as too early or too late admission, too early or too late cut-off, too early or too late release and too early or too late compression. Directions for remedying all of these faults are given.—*Am. Elec.*, December.

Condensed Steam.—Parkinson.—An article on the utilization of condensed steam in central station economies. A simple filter for removing oil from the condensed steam, to render it suitable for boiler feeding, is described and illustrated.—Lond. *Elec. Rev.*, December 18.

Traction.

Alternating-Current Traction.—Eborall.—The first part of an illustrated paper read before the Manchester Section of the (British) Institute of Electrical Engineers. For urban and interurban tramways three-phase working is out of the question, and even if the single-phase motor should ultimately become an important factor in electric railway work, for this kind of roads. With regard to working costs, a certain economy would naturally result from the substitution of transformers for rotating converting machinery in substations, but this saving would not appreciably influence the total costs of operation, on account of the increased energy consumption in the secondary network. It is hardly likely that the all-round performance of any type of alternating-current equipment will ever equal that of the corresponding direct-current equipment, at any rate under the conditions usually prevalent in urban and interurban tramway work. However perfect the phase compensation of such motors may become, the losses in them and in the distributing system must be greater, other conditions being equal, while on the other hand the maintenance charges are not likely to be less. For overhead, underground and suburban electric railways, the situation seems a little more favorable to alternating-current working; but the commercial success of such lines turns very largely upon the question of rapid acceleration obtained at minimum cost with the help of a simple and flexible arrangement, and in this respect the direct-current equipment is superior to the alternating-current equipment, no matter what arrangements are made with regard to the starting and speed control of the motors. For branch lines and light railways and for high-speed railways where the distances are considerable and acceleration periods are relatively insignificant, the case is quite different. For such work the disadvantages of three-phase working are by no means serious. The author then discusses the principal features of three-phase motors and gives in a table a comparison between typical standard high-speed 500-volt railway motors of the three-phase and direct-current types, the former being arranged for 25 cycles. There is no great difference between the weight and dimensions of the two types of motor, what difference there is being in favor of the direct-current motor. The cost of the three-phase equipment is considerable in excess of that for direct current. Considered from the general engineering standpoint and from the point of view of cost of up-keep, the three-phase motor has the advantage. The speed control of the three-phase motor on tramways must be either a rheostatic or tandem-parallel control. With control by means of rotor resistances, a starting torque per motor equal to nearly three times the normal full-load torque is available for acceleration if necessary, provided the normal pressure is maintained at the motors; but it is accompanied by large losses in the rotor resistances. Still larger torques can be obtained for quicker acceleration if desired by increasing the pressure on the motors; but the result is even greater total losses. Generally speaking, the power consumption of well-designed three-phase motors during the starting period, when employing rotor resistance control, is of the order of 20 per cent. more than that required by the corresponding direct-current motors, starting under the same conditions, with the help of series-parallel control. This is the case for moderate accelerations, while for very rapid accelerations the difference in favor of the direct-current equipment is still more marked. The paper is to be concluded.—Lond. *Elec.*, December 18.

Single-Phase Traction with Speed Regulation.—Latour.—An article in which he says that the following three types of commutator motors may be considered as suitable for single-phase traction, all three allowing perfect operation near synchronism: First, the repulsion motor with a stator winding distributed in slots; second, the shunt motor without phase difference which starts as a repulsion motor; third, the series motor without phase difference. The second type, which may be wound for low or high voltages, is suitable for producing a uniform and nearly constant speed; i. e., for high-speed roads. The motor acts as generator and energy is thus given back, as soon as the speed of the motor is higher than the no-load speed. The excitation must not necessarily be single-phase, but this is the simplest arrangement. The first and third motor types mentioned above are alone suitable for traction with varying speed. The advantage of the repulsion motor is that it may be built directly for a high voltage, while the series motor is essentially a low-voltage motor. On the other hand, the series motor has that advantage over the repulsion motor that during starting the magnetizing current of the former is much smaller and may be reduced to zero when the motor has run up to speed. Whether a repulsion motor or a series motor is used, it is necessary to devise a suitable method for regulating the torque. If the voltage supplied to the motor is constant the torque depends only on the position of the brushes on the commutator, with relation to the terminal points of the stator. By a suitable regulation of the brush holder it is thus possible to obtain the positive or negative torque for a certain speed and the effect braking from full speed to stop without any loss of energy. Since the regulation of the brush holder may involve mechanical difficulties, it is preferable not to change the position of the brushes on the commutator, but the points where the current enters and leaves the stator. For this purpose the stator is connected with an apparatus, similar to a commutator, as shown in Fig. 2, and this

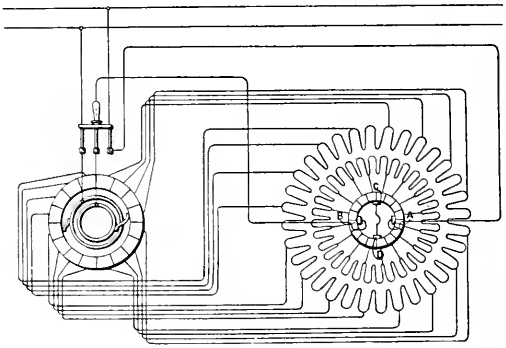

FIG. 2.—DIAGRAM OF CONNECTIONS.

apparatus is placed near the stand of the motorman. The author proposes to discuss the problem of starting without sparks at the commutator in a future article.—*Elek. Zeit.*, December 17.

Alternating-Current Traction.—In an editorial discussion Lincoln's recent paper is said to be a fair statement of the claims for the alternating-current system; on the fact of the showing made, it is thought the general opinion will be that the advantages of the alternating-current system are not sufficient to justify a change from the direct-current system. The main reason why the alternating system is cheaper in first cost is that the current is distributed at very high voltage; but the use of a high voltage is considered to be economy at the expense of safety.—*Eng. News*, December 17.

Multiple-Unit Control.—An illustrated description, by Guarini, of the Siemens-Schuckert system in *Elec. Rev.*, December 19. A long illustrated paper, by Niethammer, gives a general review of the subject, with descriptions of the systems of Sprague, General Electric Company, Westinghouse Company and Siemens-Schuckert. In the discussion Adler described the pneumatic control system of Anvert.—*Zeit. f. Elek.*, December 6, 13.

Installations, Systems and Appliances.

Cut-Outs.—Garrard.—A communication referring to the recent failure of a British supply station. He does not believe that the insertion of a maximum cut-out in each generator circuit would prevent such a failure, since if a large current is produced and causes one or more of the maximum current cut-outs to open, the current is piled up in the other machines, whose maximum cut-outs would, therefore, open, one after the other, and the entire station would be shut down. He claims that the only automatic cut-out required in a generator circuit is a reverse-current cut-out; this should, however, not be set to operate at too low a reverse current. A safe value would be about 3 per cent. of the full-load current. The only form of proper reverse continuous-current cut-out can take is that of a polarized relay. This can be adjusted to operate at any exact value of reverse current, and will not operate under any other conditions. The actuating apparatus for knocking out the switch is a tripping coil, the circuit of which is made by the relay. The current for energizing the tripping coil can be taken from an external source, which is the better way, or it may be taken from the same bus-bars that the generators are feeding. It is easy to construct the trip coil with such a large factor of safety that it has sufficient power to open the switch, even if the bus-bar voltage is only ⅕ of the normal value. In an editorial note on this subject doubt is expressed whether central station engineers will share the author's views as to the superiority of the reverse-current cut-outs over other protective devices for direct-current dynamos. The reason of the antipathy of practical men to minimum and return-current cut-outs is that in practice it is found that they occasionally cut off the undamaged generators. In the case of a generating station of fairly large size, there is little danger in using maximum cut-outs between the dynamos and the bus-bars.—Lond. *Elec.*, December 18.

Durban.—The conclusion of the illustrated description of the traction and lighting system of Durban in South Africa. There are 17 miles of tramway track and a negative booster cable has been provided. To meet the large demand for motive power, some 6¼ miles of special motor mains have been laid in various places in town for a 500-volt direct-current supply with switch boxes, which are interconnected to the traction switch boxes, the rails being also used as the return. Where motor mains are laid in streets off the tram routes, a bare copper return has also been laid connected with the nearest rail. The motor mains are also made use of for the street arc lighting; the cables for the various circuits are taken from the nearest switch box up the traction pole, where they are connected to the bare overhead mains; there are about 6 miles of streets so lighted by 155 lamps, arranged in groups of five in series, with a resistance between the last lamp and the rail connection for the return circuit. For the lighting system alternating current with high-tension transmission is used; there are 14 transformer stations, containing transformers mostly of 30 kw.—Lond. *Elec. Rev.*, December 18.

Reconstructed and New Central Station.—An illustrated description of the plant of the Electric Light Company at Meriden, Conn. The old equipment consisted of six engines belted to arc machines and Eddy generators having capacities of 25 to 40 kw. These were replaced at seasons of light load by a 150-kw alternator and a 125 and a 225-kw direct-current generator. The prime-movers are all of the vertical compound type and can be controlled from the boiler room or from the engine room. Prior to the reconstruction the line losses averaged about 20 per cent. and the losses from the engine cylinder to the switchboard 30 per cent. By substituting enclosed for open-arc lamps, the line losses were reduced one-third, and by changing from direct-current series to alternating-current series, the total efficiency of the plant was raised to over 75 per cent. This system was installed for street arcs and the commercial arcs were transferred to a three-wire direct-current system so as to place them more under the control of the customer, and upon a meter rather than upon a contract basis. The old three-wire, 220-volt system was retained for the incandescent lamp service, but the losses between the station and the distributing centers were considerably reduced by the addition of more copper. The power service is almost entirely upon this system, and where this service assumes large proportions special feeders are run from the station in order to prevent fluctuations upon the lighting mains. The power factor of the arc light system averages from 70 to 75 per cent.—*Am. Elec.*, December.

Bradford.—The first part of a fully illustrated article on recent extensions of the Bradford central station, which was the first municipal lighting station in England, having started supply in 1899. A system for hiring out motors is in use, which has met with success, since at the end of 1902 some 641 motors were on hire out of a total of 913 motors, representing 4,398 hp connected. The latter figure has since grown to nearly 5,000. The new generating station contains 14 high-speed engines, with a total horse-power of 6,500; there are six 700-amp., 230-volt balancers on the lighting network; six 700-hp compound generators, giving either 750 amp. at 500 to 550 volts for traction or being run as shunt machines across the outers of the lighting network at 460 volts; and for 300-hp machines, which may be used the same way. In the evening, when the traction plant is closed down, a 100-kw motor-generator is used for transforming lighting current for traction service.—Lond. *Elec. Rev.*, December 18.

REFERENCE.

Charging for Electrical Energy.—CRAPPER.—A paper read before the Leeds Section of the (British) Institute of Electrical Engineers. He discusses the principles of the uniform meter rate and of two-rate meters. If a central station could operate at an approximately constant load for 24 hours per day, the service would be an ideal one and the uniform rate would be the ideal rate; but at present a uniform rate for all purposes and at all times is not only impracticable, but unjust. He advocates a differential rate in some form as the most workable system provided the initial rate is not too high.—Lond. *Elec.*, December 18.

WIRES, WIRING AND CONDUITS.

High-Tension Porcelain Insulators.—FRIESE.—An illustrated account of an experimental investigation. On high-tension lines, porcelain insulators behave like condensers, the wire corresponding to one plate, the earth to the other plate of the condenser and the porcelain mass to the dielectrics. The capacities of these condensers are to be considered to be connected in parallel among themselves and with the capacity of the transmission line against earth. The author has tested two different types of insulators, the results being given in tables and diagrams. The capacity of the insulators is small, although not negligible, since it increases the capacity of the line itself against earth by a few per cent. The capacity and dielectric constant were found to be independent of the voltage for both insulators. For one insulator the loss was found to be proportional to the square of the voltage, while for the other insulator type tested it was proportional to about the 226th power of the voltage.—*Elek. Zeit.*, December 17.

REFERENCES.

Losses in High-Tension Cables.—ROTH.—A communication referring to the investigation of Apt and Mauritius, recently abstracted in the Digest. He doubts whether the "loss figures," given by them for various insulating materials, are an exact indication of their quality, since the authors have not correctly taken into account the thickness of the insulating layer. He believes that their method of testing insulating materials gives correct results only when cables with equal cross-section and with equal thickness of insulation are compared.—*Elek. Zeit.*, December 17.

Cables of South Africa.—An illustrated article on the change which is now being made in Johannesburg from overhead electric wires to underground cables. The high-tension voltage is 3,000, while the low-tension distribution is by three-wire network with 400 volts across the outers. At present 15 miles of underground cables have been laid and this change is to go on steadily.—Lond. *Elec. Rev.*, December 11.

ELECTRO-PHYSICS AND MAGNETISM.

Stationary Electric Waves.—MOLLOY.—A paper read before the Dublin Section of the (British) Institution of Electrical Engineers. The experimental apparatus used by the author consisted of an induction coil giving from 20,000 to 30,000 volts, two Leyden jars, arranged so that the capacity of the circuit might be varied by placing them in series or parallel, and two coils, the self-induction of which could be varied within wide limits by means of sliding-contact pieces. The frequency of the oscillations was of the order 100,000 to 1,000,000 periods per second, and the number of oscillations in each single spark was 8 to 10. An analogy was drawn between an organ pipe and an electric radiator, in both of which the minimum changes of pressure occur at the open end and the maximum at the closed end. Though the principle of resonance will protect the secrecy of wireless telegraphy messages over a very large area near the receiving station, there always will be an area near the transmitting station over which resonance cannot afford complete protection. He showed this by bringing an untuned receiver into the neighborhood of the transmitter. As it approached the radiator, the receiver responded fully to waves emitted, and successfully tapped the message. The second part of the paper dealt with the higher harmonics, and for their exhibition a long vertical coil was used. A vacuum tube was placed in the field of this coil and the oscillator circuit was first tuned to the fundamental of the coil, the bottom of which was connected to earth; an effect as of a web of light, intense at the upper part, and gradually fading towards the bottom, took place when stationary electric waves were set up in the coil. Subsequently the oscillating circuit was tuned successively to the first, second and third harmonics of the fundamental proper to the coil, and the maxima and minima of the luminous discharge were evident. In these experiments the upper end of the coil was insulated, in which condition it follows the laws of a closed organ pipe, producing only odd partials; that is, n, $3n$, $5n$ vibrations per second. By connecting the upper end to earth it is possible to produce all the partials, n, $2n$, $3n$, etc.—Lond. *Elec.*, December 18.

Radium and Atomic Theories.—RAMSAY.—A short summary of our knowledge on radium. Concerning the transformation of radium into helium, he makes the following remarks: Just as there is a limit to the possible number of atoms in a compound of carbon and hydrogen, so there may be a limit to the atomic weight of an element. Those elements with high atomic weight, such as thorium, uranium and radium, are apparently decomposing into elements with low atomic weight; in doing so they give off heat and also possess the curious property of radioactivity. What these elements are is unknown, except in one case; one of the products of the decomposition of the emanation from radium is helium. Whether the process be reversed, no one knows. If gold, which has a high atomic weight, is changing, it is much more likely that it is being converted into silver and copper than is being formed from them. At this stage, however, speculation is futile. More experiments are required.—From Lond. *Mail* in *Scient. Am.*, January 2.

ELECTRO-CHEMISTRY AND BATTERIES.

Electrolytic Formation of Lead Peroxide from Lead.—ROKOTNITZ.—A long article giving the results of laboratory tests on the electrolytic production of lead peroxide from lead with various electrolytes. With acid solutions the efficiency was better than with alkaline solutions. In pure sulphuric acid solution the output, however, is very small, but improves if such substances are added which first produces another lead compound from which peroxide can be formed more easily. He obtained the best results with an electrolyte containing 46.7 grammes of potassium sulphate and 30 grammes of potassium chlorate, in which case the ampere-hour efficiency of the peroxide formation was over 80 per cent.—*Centralblatt f. Accum.*, September 15, October 1, 15; November 1, 15.

Electrogalvanizing.—GRAEBRAN.—A description of some experiments made on plating zinc on iron, especially for plating the sides of vessels with zinc. He obtained the best results with a solution containing 6,000 grammes of water, 1,200 grammes of zinc sulphate and 60 grammes of sulphuric acid of 24° Baume. With a current density of 6 amp. per square decimeter and circulation of the solution the ampere-hour efficiency is nearly 100 per cent. An apparatus for plating the sides of a vessel with zinc is described which is essentially a nozzle through which the electrolyte is circulated, and which is pressed against the side of the vessel, the latter being, of course, the cathode. It is especially important that any soldered places should be plated with zinc as otherwise a galvanic action is set up.—*Elek. Zeit.*, November 12.

REFERENCES.

Electrolytic Formation of Lead Peroxide from Lead.—PETERS.—Continuations of his long serial giving the results of laboratory tests on the use of various electrolytes for the electrolytic formation of lead perxide from lead. No summary is yet given.—*Centralblatt. f. Accum.*, December 1, 15.

Electrodeposition of Copper.—COWPER-COLES.—A long article giving brief illustrated descriptions of various processes for plating iron and zinc with copper.—*Electrochem. and Met.*, November.

Electrolytic Drilling.—COWPER-COLES.—An illustrated description of an electrolytic drilling and slotting process. A nozzle is placed against the plate to be drilled. The electrolyte is circulated in the nozzle. The metal to be drilled is the anode and a solution of sulphuric acid is the electrolyte.—*Electrochem. and Met.*, October.

Galvanic Cells.—BERTHELOT.—A translation of some of his recent papers on the theory of galvanic cells; one refers to the "relation between the intensity of the voltaic current and the manifestation of the electrolytic output"; the second to "manifest electrolytic actions developed by batteries constituted by the reaction of two liquids, one containing an acid, the other an alkali"; the third to "new experiments on the limit of intensity of the current of a battery corresponding to the manifestation of an exterior electrolytic output apparent in a voltameter."—*Sc. Am. Sup.*, December 26.

Physico-Chemical Review.—The first number of a new journal with the title, *Physikalisch-Chemisches Centralblatt*, has just appeared, in which no original articles will be published, but abstracts given of all the original articles published in various countries in the field of physical chemistry. As far as possible the abstracts will be furnished by the authors themselves and will, therefore, be printed either in German or English or French. The editor is M. Rudolphi.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Electric Thermostat.—DARWIN.—A (British) Physical Society paper, in which he describes an electric thermostat. The vessel, the temperature of which is to be maintained constant, is surrounded by oil contained in a bath. In the oil are placed two heating coils through which electric currents pass. By automatically controlling these currents, the temperature of the oil and consequently of the inner vessel, is kept very nearly constant. The control is effected by means of a Wheatstone bridge in the outer oil bath. This bridge has two opposite arms of copper and two of manganin, so that it is only balanced at some definite temperature. Its deviations from balance affect the position of a long horizontal boom attached to the suspended coil of a galvanometer. The position of the boom determines the greater or less descent of a "hit or miss" arm, which is periodically raised by a rotating cam, and can only fall to its lowest position when the galvanometer boom is to one side and allows it to pass. This position of the boom corresponds to a fall of temperature of the controlling bridge. Thus the position of the "hit or miss" arm at its lowest position depends on the temperature, and it is the variation of this position which regulates the amount of current passing through the heating coils. When the "hit or miss" arm is at its highest position, the galvanometer boom is absolutely free to move to its position of equilibrium. At every rotation of the cam the "hit or miss" arm is lowered, and if it passes the galvanometer boom a key is closed and a current passes through the "intermittent" heating coil. The current passing through the "permanent" heating coil is also automatically regulated. This apparatus is capable of keeping the temperature within 0.01° C. for a period of eight hours.—Lond. *Elec. Rev.*, December 18.

Electromagnetic Units.—E. H.—With reference to Kennelly's Institute paper and the recommendations made for the Saint Louis Electrical Congress, the writer expresses the opinion that sooner or later the c.g.s. system will become the international system of units. The metric system from which it is derived is incoherent, since the unit of density does not conform with the units of mass and volume. The fundamental unit of force varies on different points of the earth. What he says against the metric system is also to be said against the practical c.g.s. system. The absolute c.g.s. system is itself not free of fault, but represents, as Kennelly shows, the least imperfect and most coherent system. All units should get names. The nomenclature proposed by Kennelly is considered to be very simple. The editor opens the columns of his paper to a discussion of the subject.—*L'Ind. Elec.*, December 10.

REFERENCES.

Integrating Wattmeter.—An illustrated article on the construction of the Stanley wattmeter and the equipment of the Stanley Instrument Company's works.—*Elec. Rev.*, December 12.

Magnetic Vane Voltmeter or Ammeter.—BROCKSMITH.—An article, with working drawings, on the construction of a magnetic vane voltmeter or ammeter. The instrument is extremely simple, both in principle and construction, and has the advantage of being compact and neat in appearance, while being sufficiently accurate for all ordinary purposes. The article is replete with dimensioned detail drawings and all the information necessary for the building of the instrument.—*Am. Elec.*, December.

TELEGRAPHY, TELEPHONY AND SIGNALS.

Simultaneous Telegraphy and Telephony.—PFITZNER.—An illustrated description of a system of connections which has been used for several years on several telephone double lines between Brussels

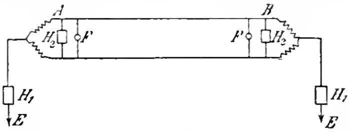

FIG. 3.—DIAGRAM OF GENERAL CONNECTIONS.

and Paris, and which enables one to telephone and simultaneously exchange telegrams between two pairs of Hughes apparatus. The general scheme of the connections is shown in Fig. 3, in which H_1 H_1 is the one pair and H_2 H_2 the other pair of Hughes apparatus; F F

are telephones and E is the earth. A modification of this scheme has also been used wih success by the German telephone department. The details of the connections are described and also given in form of diagrams.—*Elek. Zeit.*, December 17.

Magneto Switchboard for Small Exchanges.—O'BRIEN.—Telephone switchboards of the magneto type, in which the talking current for the sub-station instruments is furnished by local batteries located at each sub-station, have been almost entirely superseded in all the large and medium-sized exchanges in the country by the central energy common-battery type of switchboard. In a great number of small exchanges, however, where the expert attendance and supervision necessary for a common-battery board are not available, the simplicity and freedom from complicated circuits of the magneto board renders it especially suitable, and consequently this type of board is in use in small country exchanges to a very great extent. The author describes the wiring circuits, equipment and method of operation of a magneto switchboard having a capacity of 100 sub-station lines, which with the system in vogue in country exchanges is capable of serving as high as 400 to 500 sub-stations.—*Am. Elec.*, December.

Rapid-Type Printing Telegraph.—A note on an apparatus of Siemens and Halske based on the following principle: A disc, near the periphery of which the letters of the alphabet, figures, etc., are cut out, rotates at a speed of 2,000 r.p.m. between a moving strip of sensitive paper and a spark-gap. Every time the spark jumps the gap, that letter on the disc which happens to be at the time opposite the gap is photographed; 2,000 letters per minute may thus be recorded on the moving tape, which passes through a developing and fixing bath, out of which it emerges after about 9 seconds. To obtain good results, the spark, it is said, must occur with a punctuality by 1/400000f a second, and this has been attained by a suitable arrangement of condensers. The messages to be sent are first punched on tape, which is then rapidly run through a rotating sender by means of which corresponding current impulses in rapid succession are sent to the line.—Lond. *Elec.*, December 18.

Printing Telegraph Central Station.—GRADENWITZ.—An illustrated description of the type-printing telegraph service, recently added to the Berlin telephone service. The instrument used is a teletypewriter and the station is used at present to transmit exchange telegrams to a certain number of subscribers. It is, therefore, in the nature of our stock-ticker. The same system may, of course, be employed for transmitting telegrams from a central telegraph office to a certain number of newspaper offices.—*Sc. Am.*, December 26.

MISCELLANEOUS.

Welding Aluminum.—COWPER-COLES.—An illustrated description of various processes for welding aluminum and especially of his own machine for this purpose. The aluminum to be welded is first preheated and then the ends to be welded are pressed together so that a ring of metal is squeezed out, which is largely composed of aluminum oxide and acts as a supporting collar, the molten metal being retained within this collar. The weld is then instantaneously quenched by turning a handle, which allows water under pressure to be projected on the joint from a reservoir. The collar around the joint is afterwards filed off.—*Electrochem. and Met.*, November.

REFERENCE.

Siberia.—An article on electricity in Siberia. Six central stations are mentioned. The best equipped is at Tomsk, where "the maximum electrical output is 2,500 kw-hours per day." While there is nothing to learn from Siberian electrical engineering, yet their trade is worth having.—*Elec. Rev.*, December 12.

New Books.

THE DYNAMO. Its Theory, Design and Manufacture. By C. C. Hawkins, M.A., M.I.E.E., and F. Wallis, B.A., A.M.I.E.E. New York: The Macmillan Company. 413 illustrations.

The third edition of this book on the dynamo has been greatly enlarged, and its pages are replete with instruction. Through the general theory of the magnetic field and the production of e.m.f., the authors lead up to the dynamo in its modern form, and present their subject in a manner thoroughly up to date. It is gratifying to see how scrupulous the authors have been in mentioning the sources from which they have drawn, a custom which, in these days of literary piracy, deserves appreciation. The citation of the sources from which an author has drawn is not only a debt that he owes, but it is often extremely useful that the reader may be able to turn to the original pages for further information, and, therefore, the modern careless way of not stating the sources is greatly to be deprecated.

The eighteenth chapter treats of the theory of commutation, to which Mr. Hawkins has been a valuable contributor for many years. It is to be regretted that he does not give the theory of commutation at greater length. The chapters on the heating of dynamos and on armature reaction in alternators are excellent, the latest theoretical and experimental results having been considered. A passage from the author's preface shows the scope of the book, and we therefore cite it here: "At the same time the utmost economy in the materials and labor employed in the manufacture of a machine is imperatively called for in order to meet the increasing keenness of a world-wide competition; every pound of copper and of iron must be utilized to its fullest extent, and designs involving high-priced skilled labor must give way to simple types having easily-made interchangeable parts, with the consequent result that the machines for given outputs are smaller and more standardized. Thus in preparing a third edition it became necessary to rewrite most of the former chapters and to add several new ones."

The chapters on dynamo construction give a number of very fine cuts of modern dynamos of European and American makes, and the book as a whole will prove instructive and of interest to electrical and mechanical engineers.

Record Run of Electric Automobile.

Mr. Fred B. Whitney, clerk to the Committee on Naval Affairs of the House of Representatives, established the world's record at Washington, D. C., December 23, 1903, for an endurance run at the highest long-distance speed of an electric auto upon a single charge of storage battery. President A. L. Cline, of the local Automobile Association, acted as referee. The start was from the Dewey Hotel at 7.05 P.M. Tuesday night, December 22, in an electric Stanhope equipped with a 570-pound Porter battery and the run was made upon the streets of Washington. At 5.20 Wednesday morning the Stanhope collided with a heavy covered wagon, spilling considerable battery fluid, tearing off a tire, breaking spokes and springing axles, etc., and was hauled to a repair shop. A distance of 107.4 miles was

ELECTRIC AUTOMOBILE.

made in the actual time of 9 hours and 12 minutes, or about 12 miles per hour. The longest runs without shutting off current were 31, 23 and 21 miles. At 2 P.M. Wednesday after hasty temporary repairs had been completed the run was resumed and 13.8 miles were made in 1 hour and 30 minutes under the difficulties of a disordered machine. The Stanhope was run to its garage under its own power and showed a voltage of over 1.8 per cell and could have made more miles without accident. The total distance run was 121.2 miles in 10 hours and 32 minutes, or about 12 miles per hour. This establishes a world's record for long-distance run upon a single charge at the rate of 12 miles per hour and raises the long-distance rate one mile per hour. The world's record at 11 miles per hour was made at Cleveland, 1902, at 151 miles. The world's record at 10 miles per hour was made by Mr. F. C. Phillips, of Cleveland, at Chicago at 187 miles, using Porter battery.

New Types of Voltage Regulators for Generators.

The General Electric Company has recently placed on the market two new types of voltage regulators, designed for direct-current generators only (Fig. 1), and the other (Fig. 2), though primarily

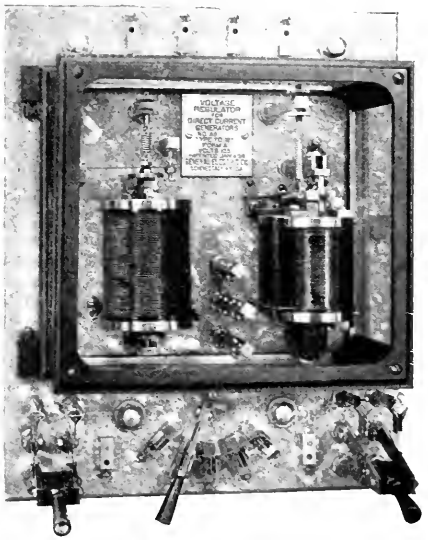

FIG. 1.—DIRECT-CURRENT REGULATOR.

designed for use with alternating-current generators, may, if provided with an exciter, be used on direct-current generators as well.

These instruments operate on the principle of rapidly opening and closing a shunt circuit across the field rheostats, the rheostats having considerable resistance turned in to give the regulator a good margin to work on. The first mentioned type is arranged to open and close

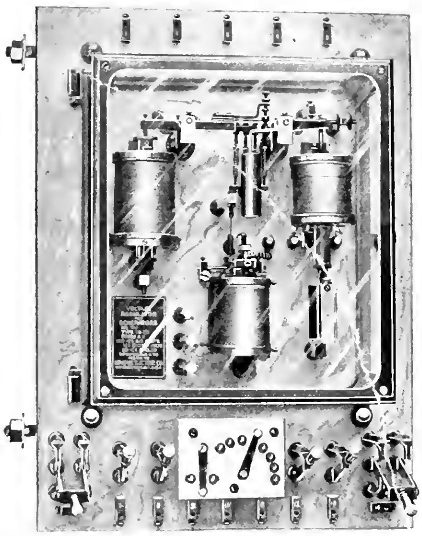

FIG. 2.—ALTERNATING-CURRENT REGULATOR.

a shunt circuit across the generator field rheostat, and the other across the exciter field rheostat.

The direct-current regulator consists of a main control magnet and relay. The relay is differentially wound, one of these windings being permanently connected to the circuit, while the other is opened and closed by the main contacts which are operated by the main control magnet. As the main contacts are opened and closed, they simultaneously open and close the relay contacts by means of the differential winding of the relay. These relay contacts open and close a shunt circuit across the generator field rheostat. To prevent injurious sparking at the relay contacts, condensers are connected in multiple across them. This regulator will maintain constant voltage on one shunt-wound generator, or will maintain constant volt-

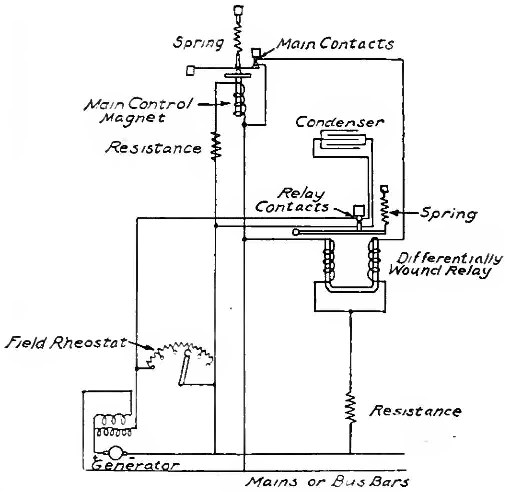

FIG. 3.—DIAGRAM OF CONNECTIONS.

age on several compound-wound generators operating in parallel, regulating, however, only one at a time. Several generators can be arranged to be controlled by one regulator, by means of the five-point

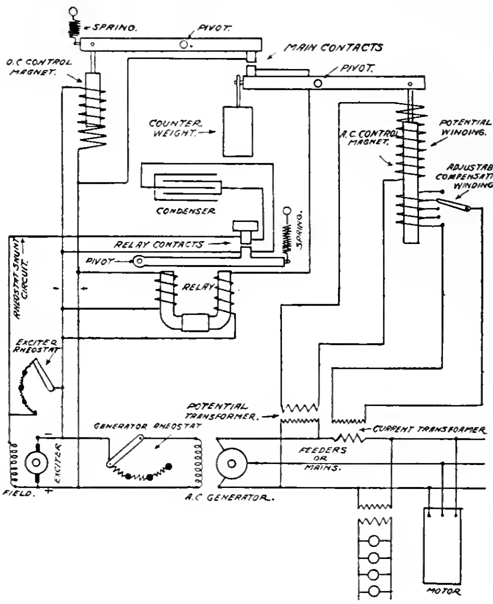

FIG. 4.—DIAGRAM OF CONNECTIONS.

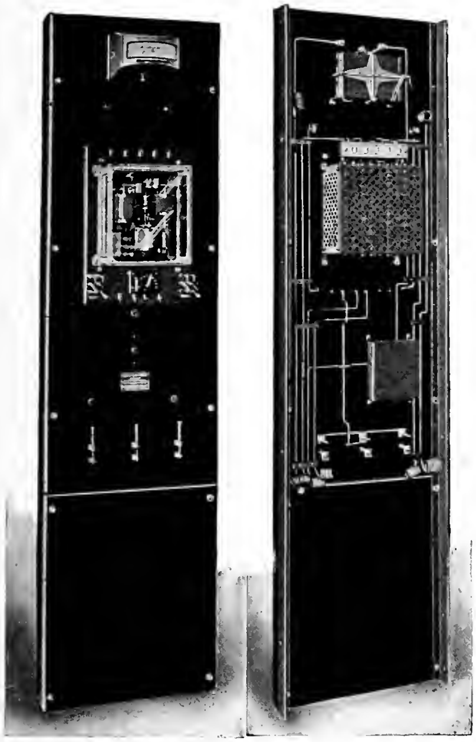
rotary switch as shown in Fig. 1. The generator being regulated has a tendency to take the sudden fluctuations of load, but it is quickly equalized between the several generators by means of the compound winding of the machines. With shunt wound generators it will be necessary to have a regulator for each generator to be regulated.

These regulators are usually arranged to maintain constant voltage at the bus-bars, but may be connected to pressure wires brought back from the centre of distribution, thus maintaining constant voltage at the centre of distribution. The connections of this regulator are shown in Fig. 3.

The second type of regulator is designed to maintain a steady (but not a constant) exciter voltage, and consists of the same direct-current control magnet and relay as the direct-current type with the addition of an alternating-current control magnet having a potential and an adjustable compensating winding. These two windings work in opposition to one another. This magnet operates the lower main contact. The magnet core and lever are arranged by means of a counterweight to come to a balance at the correct voltage. Should the alternating voltage tend to vary for any cause, it would change the position of the lower main contact, which would cause the exciter voltage either to be raised or lowered, thus overcoming the disturbing factor. Without the use of the compensating winding, the regulator will maintain a constant bus-bar voltage, and by the use



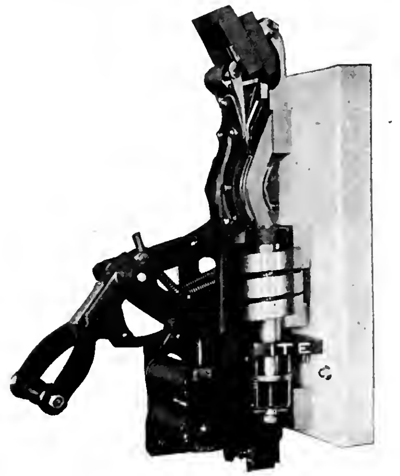
FIGS. 5 AND 6.—FRONT AND REAR VIEWS OF REGULATOR PANELS.

of the adjustable compensating winding and current transformer in the circuit to be regulated, the regulator will automatically compensate for line losses. The alternating voltage is automatically kept at its desired value by varying the exciter voltage. Once the regulator is adjusted to maintain constant voltage at the centre of distribution it will require no further adjustment, and the station voltage will be increased or decreased with the load to automatically maintain the desired voltage at the centre of distribution. This regulator is independent of temperature and frequency changes. Elementary connections are shown in Fig. 4.

These regulators are switchboard instruments in design and finish, and may be placed on the front of a switchboard panel or be placed at either end of a switchboard on rigid iron brackets made for that purpose, Figs. 5 and 6. The value of these regulators will be recognized in maintaining the desired potential on a system, regardless of variations of speed and load. It naturally results in reduced attendance at the switchboard, increased output of station and reduced lamp renewals due to perfect regulation. It is stated that there are now in service regulators of these types controlling upwards of 100,000 kw of generating apparatus.

Reverse Current Circuit Breakers for Protection of Generators in Parallel.

One of the latest types of I. T. E. automatic circuit-breakers, designed and manufactured by the Cutter Company, of Philadelphia, is the overload and reverse-current type, illustration of which is shown herewith. This circuit-breaker is especially serviceable for the protection of generators operated in parallel. In the electric railway power plant, or the lighting plant in a hotel, office building or department store, there is a time of day when the load comes on very rapidly, due to increased traffic or turning on of lights. At such a time the engineer has to start up an extra generator and throw it in parallel with the generators already carrying the load. The load, however, often increases so rapidly that the dynamos running are greatly overloaded before the extra machine can be cut into the circuit to carry its part of the load. If an engineer in his excitement, to get this generator into service, should attempt to throw it in parallel with the other generators before it is up to voltage, the ones carrying the load would also have to supply current to run this gen-



CIRCUIT-BREAKER.

erator as a motor until it was up to speed. This extra load at such a time would seriously overload the plant and possibly open the overload circuit-breakers on the generators.

To guard against such careless handling of generators, and also against open fields, etc., a reverse-current circuit-breaker is used, or rather a circuit-breaker combining the overload and reverse-current features. The reverse-current provision automatically opens the circuit-breaker on any specified reverse current, and the instrument can be provided with a calibrated scale so that it can be set to open when the reverse circuit exceeds a predetermined point. The tripping force is dependent upon the amount of reverse current and the greater the current the quicker the circuit-breaker is opened. The operation is practically independent of the voltage on the line and will open the circuit, even though the voltage fall to 25 per cent. of normal. The overload feature is the same as that used with other types of I. T. E. circuit-breakers and is positive and accurate in its calibration.

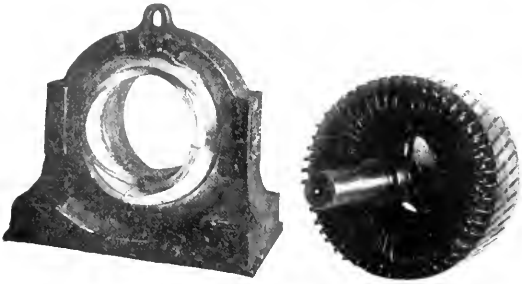
This type of circuit-breaker is also largely used for the protection of rotary converters operated in parallel. They are built plain reversal and overload and reversal in all capacities, single and double-pole, up to 12,000 amp., for use on circuits of any voltage up to 800 volts, direct current. Smaller types are used for the protection of electric automobile charging circuits and storage battery equipments of all kinds.

Freeport-Dixon Electric Railway.

The Arnold Electric Power Station Company, engineer and contractor, Chicago, Ill., has been retained by the Freeport-Dixon Electric Railway Company to prepare preliminary plans for its proposed line. The road will consist of about 35 miles of single track, and will connect the cities of Freeport and Dixon.

British Single-Phase Motor.

The Langdon-Davies Motor Company, Ltd., London, has for many years made a specialty of single-phase alternating-current motors, although they also make and supply direct-current, two-phase and multiphase motors. Their alternating-current motors, as regards the larger sizes, have a special construction of bed plate. This has the advantage of serving instead of slide rails, and further has the manufacturing advantage of reducing the size and weight of the pieces to be machined. As slide rails, it carries the weight in the plane of the motor axle and thus reduces the tendency to cant, especially with a



FIGS. 1 AND 2.—FIELD AND ARMATURE.

horizontal belt drive, and the protections on either side of the sliding part entirely avoid any sideways cant when tightening up the belt.

The fact that the above company are turning out over 2,000 hp of single-phase motors a year, and that in many cases factories have abandoned their gas and steam engines and replaced them by such motors to the extent of 200 or 300 hp, and are pleased with the result, forms a significant comment on the development effected. At Derby, which is a network having a single-phase supply, the consumption of energy for motive power for the year ending last March was 22 per cent. of the total units sold. This is a figure which will

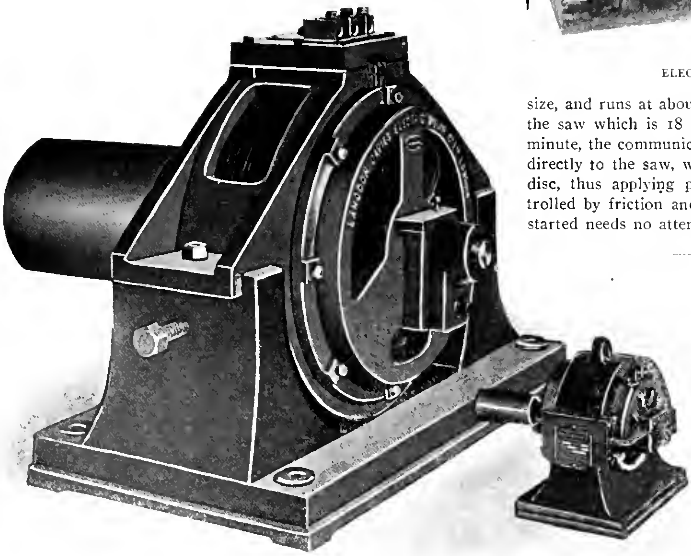


FIG. 3.—SINGLE-PHASE MOTORS.

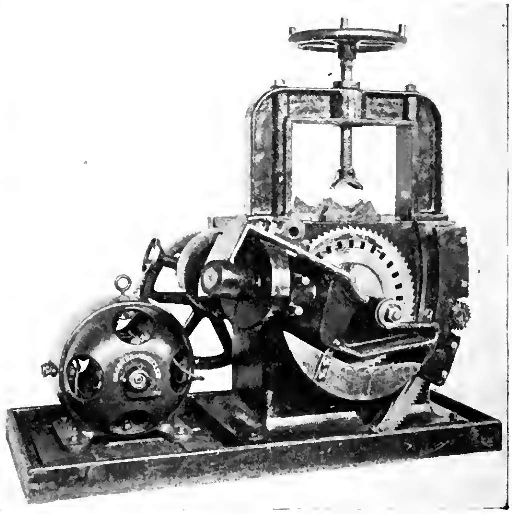
be found to compare very well with any direct-current station of a similar size.

The repairs and renewals of the induction motors, especially those without slip rings, which can be adopted for nearly all purposes, are an almost nominal amount. The accompanying engravings show the windings of the rotor and stator of the smaller motors.

A Motor-Driven Cold Metal Saw.

A portable cold metal sawing outfit is illustrated herewith. It is a standard Higley saw, designed for cutting bar stock, to give lengths at a rapid rate, and is marketed by the J. R. Vandyck Company, of New York. The distance between the uprights of the clamp is 16 inches and the height under the arch of the clamp is 12 inches. The tool is capable of cutting round stock up to 7 inches in diameter, 12-inch I-beams, etc. The drive was arranged by substituting a sprocket for the belt pulley and connecting to the motor by a Renold silent chain. The supporting frame of the saw is swiveled about the sprocket shaft as an axis, and feeding is accomplished by swinging the saw up under the work, the feeding and returning being automatic. The motor is of the Crocker-Wheeler make, of 3-hp



ELECTRICALLY-DRIVEN METAL SAW.

size, and runs at about 725 h.p.m., when on 120 volts. At this speed the saw which is 18 inches in diameter makes about 4½ turns per minute, the communication being through a spur gear and bevel gear directly to the saw, where a sprocket engages in perforations in the disc, thus applying power very near the teeth. The feed is controlled by friction and is adjustable so that the machine when once started needs no attention until its job is finished.

Test in Wireless Telegraphy.

On the morning of Saturday, December 5, an interesting test in wireless telegraphy was made between Fort Wright, New London, and Fort Schuyler, New York, a distance of about 100 miles. The test was made by the De Forest Company on behalf of the Government. Three messages of about thirty words apiece were sent by General Greely, of the United States Signal Corps, from Fort Wright to Captain Reber at Fort Schuyler. The particular interest of thetest lies in the fact that certain conditions were imposed which made it very difficult to send a distance of 100 miles, namely, the height of the antennæ at the two stations was limited to 140 feet, and the power at the sending end to 3 kilowatts. The Government is erecting two stations in Alaska about 100 miles apart, and General Greely wished to satisfy himself that messages could be transmitted over this distance under the conditions stated. A number of army officers witnessed the test.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—Improvement was the feature in the stock market throughout the week, but there was a sharp reaction at the close. Financial conditions are considered sound and healthy. Money is in good demand for legitimate purposes, and the supply resulting from the release of funds engaged in crop movement, with some $25,000,000 of foreign gold imported, gives promise of abundant ease in the future. Amalgamated Copper was heaviest among the active stocks, and lost 4¾ per cent. Its decline was a depressing influence upon other stocks on account of its recognized relation to the Standard party. The traction and electric securities all show advances on a fairly good business, the greatest relative activity being in General Electric, of which 12,460 shares were sold at prices ranging from 171½ to 180, the closing figure being 176, a net gain of 4½ points. Activity is also noted in Westinghouse common, 18,000 shares having changed hands, the extreme prices being 168 and 180, the former being also the closing quotation, ex-dividend, and representing a net gain of 2½ points. The preferred stock gained ½ point net, closing at 193½. In tractions B. R. T. closed with a net loss of 4⅛ points, the last price being 48¾. Metropolitan Street Railway closed at 121½, being a net gain of 1⅝ points. American Telephone & Telegraph closed with a gain of 2⅛ points, at 128⅛, and Western Union at 86½, a ¼ point better than the last previous record. Following are the closing quotations of January 5:

BELL TELEPHONE.—A Boston telephone official is quoted as follows: "I believe the result of President Fish's recent visit to the West will be an active campaign during the coming spring against the independents in the Middle West with a view of preventing their increasing their hold upon the city of Chicago. The battle will take place in the territory of the Central Union Company in the Middle West, where competition is the hottest and the field that General Sabin, of San Francisco, attempted to conquer. It will have to be done by funds furnished direct by the American Company, as the Central Union Company is already up to its bond limit and, notwithstanding its stock has been cut in two, the market value is far below 100. All the subsidiary companies with their reports sent to Gen. Thomas Sherwin, auditor, in December, will estimate the cost of next year's extensions and show the amount of money required. Based on the winter orders for poles and cables already placed, the extensions will exceed those of this year on all lines and at least $30,000,000 will be asked for, although the home office may cut this amount on account of the money stringency, to $25,000,000. With Bell stock selling at $126, it is quite probable that the new money will be raised by bond issues instead of selling at 7½ per cent. stock at par. Based upon the recent sale of Atchison bonds and the fact that all the Bell bonds previously issued have been distributed, the company ought to be able to market a block of $25,000,000 to net above 90, basing the rate fixed to be 4 per cent., a saving of say 3 per cent., or $750,000 annually."

GENERAL ELECTRIC.—On the subject of General Electric business in 1903-4, the *Wall Street Journal* says: "We understand that the General Electric will close the year with substantially the same net figures as for 1902. The gross business has been larger, but the expense of material, power and labor has been increased. The electric manufacturing companies are fairly well supplied with orders, but will doubtless enter the year with a reduced amount as compared with a year ago. The problem of high costs at the present time, with the prospects for a falling off in business at the end of the year, must be soon taken up, and it is expected that the orders now in hand can be so judiciously distributed over the year as to meet a reduced output for the whole of the year 1904 with some measure of economy in costs. This may involve a reduction in forces at Schenectady and Lynn and some readjustment of wages. A few departments of the company are still overcrowded, but in others there is a surplus of labor. The problem of 1904 is one of economic readjustments to irregular conditions."

BOSTON STOCK TICKERS.—The announcement is made that the Commercial-Financial Press Association has acquired the Boston *Financial News* and the New England stock quotation service, and through association with the New York News Bureau has become Boston correspondent for that association. By reason of the changes, on and after January 1 the service of the Boston *Financial News* will be conducted directly by the Commercial-Financial Press Association, the absolute control of which is in the hands of an interest closely allied with the New York News Bureau. The new management will install within the next two or three months an electric delivery service by means of the Burry bulletin printer, which has for some years been successfully operated in New York. The publication offices of the new association are at 35 Congress Street, and the business offices at 22 Congress Street. Charles B. Strecker is president and general manager of the company.

B. R. T. LEASE.—It was stated on Wall Street last week, in positive terms and from reliable authority, that the Brooklyn Rapid Transit system had been taken under lease by the Interborough Company on a 4 per cent. guarantee stock. The negotiations have not been closed, it is asserted, because of the insistence of the Rockefeller interests on a demand for an increase of the guarantee to 5 per cent. after a few years. The Interborough people object to an increase in less than ten years. The proposition to lease, however, has been absolutely agreed upon.

Commercial Intelligence.

THE WEEK IN TRADE.—Generally the earnings of the railroads remain good, and while the extreme high water mark may in some cases not be maintained on the majority of roads the reports are encouraging and the handsome surpluses over dividends paid, and the belief that it will be practical to reduce expenses in the future give reason to expect an indefinite continuance of the present rate of distribution, with some increases more than possible. Trade conditions in general are reported favorable, and there is a decidedly hopeful feeling as to new year's business. The extreme cold weather checked retail trade temporarily, but this is a mere seasonable incident, the future outlook being very satisfactory. No particular changes are noted in the iron and steel trade, while the other metals, including copper, remain practically unchanged from the last quotations.

DORTMUND ELECTRIC ROAD.—The commissioners of the Dortmund suburban district have decided to build an electric railroad at the district's expense. The General Electric Company (Allgemeine Elektrizitätsgesellschaft), of Berlin, whose bid of 1,640,000 marks ($390,320) has been accepted, will build the road and operate the same, under a concession, for a period of ten years. New electric roads are being built in many European cities by this company.

JOHN-MANVILLE COMPANY.—The British Johns-Manville Company, Limited, has been formed in London for the purpose of undertaking the selling agency for the specialties of the H. W. Johns-Manville Company, 100 William Street, New York. The capital of the company is $25,000. The directors will be Edward Bergtheil, of the London firm of Bergtheil & Young; H. J. Joseph, who will also be the manager of the company, and G. W. Becker, formerly of the New York offices.

HOBART ELECTRIC MANUFACTURING COMPANY.—An announcement has been received of the reorganization of the Hobart Electric Manufacturing Company, of Troy, Ohio, which went into effect on January 1. The purpose of this change is to materially increase the capacity of its factory. The capital stock of the company has been increased and contracts are now being entered into for a large and modern addition to its already well-equipped factory, which will enable it to treble its output. The secretary and treasurer, who held a controlling interest in the old company, will retain their holdings in the new organization and will be actively engaged in its management. Mr. C. C. Hobart, who has been so long identified with this company, retires from an active interest in the reorganized company. The Hobart Electric Manufacturing Company, although it has made little effort to force itself on the notice of the public, has, nevertheless, more than quadrupled its business within the last few years. A very large proportion of its output of dynamos and motors has been disposed of to concerns who are constant users of electrical machinery, and who, having found the Hobart apparatus to be thoroughly efficient and satisfactory, have favored it with continued patronage. In a quiet way the Hobart Electric Manufacturing Company has increased its business to such an extent that even with its constantly increasing facilities it has been unable to keep up with its orders. A number of contracts of from $10,000 to $25,000 each have been secured within the last year, so that the problem of selling has not caused much anxiety as compared with the problem of deliveries. Starting a number of years ago with the manufacture of a low-priced dynamo and motor, the Hobart Company has now come to be recognized as manufacturers of a standard machine. Especial attention has been paid by it to those parts of a machine which most frequently cause annoyance in operation. Aside from a standard line of dynamos and motors, this company also manufactures a dynamo designed especially for use with gas and gasoline engines. This machine adds to a standard machine a heavy fly-wheel and a third bearing to support it. It is a successful dynamo for overcoming the flicker in the lights caused by the irregular impulses of gas engines. A direct-connected electric coffee mill for use in groceries manufactured by this company has also met with popular favor.

A NEW TELEPHONE MANUFACTURING COMPANY.—The Dean Electric Company has been incorporated under the laws of the State of Ohio by Samuel B. Rawson, I. H. Griswold, T. M. Brush, A. E. Barker and W. W. Dean, to engage in the telephone manufacturing business at Elyria, Ohio, at which point a modern factory building will be erected on the main line of the Lake Shore Railroad. The names of several of the incorporators will be recognized as those of prime movers in the independent telephone field. Messrs. Rawson, Griswold and Brush are the founders and builders of a large number of exchanges in the States of New York and Ohio, among which are Albany, Schenectady, Cohoes, Niagara Falls, Elyria, Ohio, and numerous others. Mr. A. E. Barker has been connected with the engineering staff of the Kellogg Switchboard & Supply Company, of Chicago, having built the Detroit and New Orleans exchanges. He has also had charge of the sales end of the Kellogg Switchboard & Supply Company, with the title of sales manager. Mr. Dean has been connected with the telephone business for about 22 years and has been with the following companies: The Bell Telephone Company, of Missouri, at St. Louis; the Union Telefonica Company, Buenos Ayres, South America; the American Bell Telephone Company, of Boston; the Western Electric Company, of Chicago, and the Kellogg Switchboard & Supply Company, of the same city. The officers of the new company are as follows: Samuel B. Rawson, president; William W. Dean, vice-president and chief engineer; T. M. Brush, treasurer; A. E. Barker, secretary and general manager.

FIRE AT 131 LIBERTY STREET, NEW YORK.—Fire broke out about 3 A.M., January 5, at 131 Liberty Street, in which building a number of electrical concerns are located. The flames started on the sixth or top floor, in the printing plant of Boschen & Wefer The entire floor is completely gutted and the roof burned off. The amount of water which was used to quench the fire must have been enormous, as practically all the ceilings on the floors below leaked very badly when seen by a representative of the ELECTRCIAL WORLD AND ENGINEER. On the fourth floor J. P. Hall, the electrical engineer and contractor, has his offices. It was said that the damage done there would amount to about $1,500. The D. H. Darrin Company, manufacturers of elevators, etc., has its factory on the third floor. About $2,000 worth of damage is estimated to have been done. On the second floor the Automatic Switch Company has its plant. About $2,000 worth of damage is estimated to have occurred. The D. H. Darrin Company has its offices on the first floor. About $1,000 is expected to cover the damage. On the ground floor B. F. Sturtevant & Co.'s store and offices are located. It is believed that $1,000 will cover the damage done there. The fire is reputed to have started by the falling of a live coal out of a stove used by a plumber, who was making some repairs on the top floor. Most of the damage done is covered by insurance.

CHAMBLY POWER HOUSE.—In connection with our recent important and long article on electric light and power at Montreal, in the description of the Chambly power plant, it should have been stated that the McCormick water wheels referred to were built by the S. Morgan Smith Company, of York, Pa. One of our drawings showed two pairs of wheels on a line direct-connected to a generator, the wheels and draft boxes being placed in a concrete flume. This was the way the wheels were set when the plant was originally built. As remodeled, however, the plant has the water wheels and draft boxes on the inside of steel penstocks, the ends of which were shown in another of the cuts. At the time the dam at Chambly "went out" some months ago, the water wheels were placed in steel penstocks because it was feared that the concrete flumes might not stand much longer.

SOME HARRISBURG ENGINE ORDERS.—The engineering and contracting firm of Mackenzie, Quarrier & Ferguson, 114 Liberty Street, New York, has taken an order for a 150-hp Harisburg standard simple engine from the Ironclad Manufacturing Company, of Brooklyn, direct-connected to a 100-kw generator. The equipment will be used for both light and power. A 75-hp Harrisburg simple engine has been ordered for lighting Healy's Restaurant, New York. The generator will be a 50-kw one of Western Electric make. Among foreign orders received within the past few days is one for a 125-hp engine to be belted to a 75-kw General Electric generator for shipment to Chili for lighting use.

MEXICAN LIGHT AND POWER SCHEME.—Mexican advices state that Mr. James Kilton has secured a contract for furnishing electric light and power and the construction of a system of water works at Matehuela, a city of some 15,000 inhabitants, in the State of San Luis Potosi, Mexico. The plans include the building of four electric generating plants, which are to obtain power from water to be piped from large natural springs located on top of a mountain 1,000 ft. above the city and about 22 miles distant. The water of these springs is to be piped to the power stations and thence conveyed to Matchuela for the purpose of supplying the mains of the water works system.

EQUIPMENT FOR MEXICAN MINES.—The Penoles Mining Company, which operates extensive properties at Maprine, Mexico, placed recently contracts for considerable electrical equipment for driving hoists, pumps and compressors and lighting the mines. The contracts called for a 2,500-hp plant. The Allis-Chalmers Company, New York, secured the order for the engines, while the General Electric Company obtained the order for the generators—three-phase, alternating-current type.

LIGHT AND POWER STATION AT DRAMMEN, NORWAY.—A new light and power station has just been opened at Drammen, Norway. This station receives its power from Gravfos Falls over a 23½-mile transmission line. The entire electrical equipment, both for the station at the Falls and the one in the city, was furnished by the Oerlikon Company. The power station at the Falls has a capacity of 5,400 hp, and consists of six 900-hp units. The current is transmitted at a potential of 25,000 volts.

EQUIPMENT FOR LEHIGH CEMENT PLANT.—The Lehigh Portland Cement Company is to extend its plant at Ormrod, Pa. Considerable new equipment has already been contracted for. Mackenzie, Quarrier & Ferguson, 114 Liberty Street, New York, took an order for a 340-hp tandem-compound Harrisburg standard engine, to be direct-connected to a 225-hp General Electric generator. Several motors are also to be installed.

BALL ENGINE ORDERS.—Dilworth, Porter & Co., Limited, Pittsburg, Pa., has recently placed a contract for three direct-connected units, the engines for which are to be furnished by the Ball Engine Company, Erie, Pa. The Sailors' and Soldiers' Home, of Grand Island, Neb., has contracted for a direct-connected unit. The Ball Engine Company, Erie, Pa., will build the engine.

THE DUNKIRK POWER & HEATING COMPANY, of Dunkirk, N. Y., has just completed the installation of the following units in addition to the previous plant: A 225-hp tubular boiler, under which is a Murphy automatic smokeless furnace; a 20 by 42 simple non-condensing Nordberg Corliss engine; a 250-kw. belted Western Electric, moderate speed, generator and switchboard appliances. Exhaust steam is used for steam heating through underground mains.

MEXICAN HYDRAULIC PLANT PROJECTED.—A hydraulic plant is about to be built on the River Tanoco at a place called Chorro Grande, in the State of Vera Cruz, Mexico. Filiberto Romero, of Vera Cruz, is primarily interested in the project. It is proposed to develop current for lighting and power use in the vicinity.

KEYSTONE ELECTRIC COMPANY has recently installed a 450-kw, 220-volt unit for the Erie Electric Light Company, of Erie, Pa. Mr. H. B. Coho is now vice-president and general manager of the Keystone Company, to which he is giving his personal attention.

General News.

THE TELEPHONE.

MEDORA, ILL.—The Medora Telephone Company, has been incorporated with a capital stock of $10,000. The incorporators are John Payne, Oliver Pirwin and William J. Bell.

BLOOMINGTON, ILL.—The Washington City Rural Telephone Company has purchased the Washington Telephone Exchange from Receiver Heald, of the Peoria and Eastern Telephone Company. Paul Goddard is president of the new company.

ALEXANDRIA, IND.—The Central Union Telephone Company will put in a new switchboard and change its system from magneto to the central energy system.

VINCENNES, IND.—The report of the first year for the Knox County Home Telephone Company shows a growth of 1300 connections with lines south, north, east and west. By Jan. 10 the Princeton line will be finished. The Sullivan connection has been in operation two months, and a long distance line will connect Indianapolis in the near future.

NOBLESVILLE, IND.—On Dec. 24, the entire interior of the Home Telephone Company exchange in this city was burned, the result of a cable coming in contact with the trolley wire of the Indianapolis-Northern Traction Company. Over 200 telephones were burned out. Many patrons who answered the false call were shocked and a number were burned.

CORYDON, IND.—The Cumberland Telephone Company is putting forth extraordinary efforts to enlarge its service in Southern Indiana. The company has agents out inducing farmers to build their own lines promising them connection and service under very favorable terms. It is claimed a large number of lines will be built by the farmers under the stimulus of the favorable conditions offered.

INDIANAPOLIS, IND.—The Central Union Telephone Company is arranging to divide the State into four districts, with a district superintendent in each division. The four district headquarters will be at Indanapolis, Logansport, Anderson and Terre Haute. A fifth division headquarters may be established at Ft. Wayne later on. The officials say the work of extending the service is being carried on so rapidly that it is no longer possible to handle it from one central point. Under the new plan the division superintendents will work under the general district superintendent in this city. R. A. Swan has been selected for Anderson, J. H. Sheppler for Terre Haute, and M. D. Atwater for the Indianapolis district.

BOONE, IA.—The headquarters of the Iowa Telephone Company are to be removed from Davenport to Des Moines.

COUNCIL BLUFFS, IA.—Mr. Thomas D. Metcalf and other local parties are endeavoring to revive interest in an independent telephone system, a movement for which was agitated something over a year ago, but failed to succeed because of the strong opposition by the Bell people.

PAXICO, KAN.—The Paxico Telephone Company has been incorporated with a capital stock of $2100.

REPUBLIC CITY, KAN.—The Republic City Telephone Company has been incorporated with a capital stock of $2500.

BELLVILLE, KAN.—The Bellville Independent Telephone Company has been incorporated with a capital stock of $35,000.

MARYSVILLE, KAN.—The Marysville Telephone Company plans to erect a new switchboard of from 300 to 400 drops capacity. The company will build quite a good many party lines during 1904. It has 234 telephones installed, the user of each paying $1 and $2 a year, according to service.

FRANKFORT, KY.—The Kirksville Telephone Company has been incorporated with a capital stock of $7500.

KENSINGTON, MD.—The Kensington Telephone Company is the name of a new concern organized here with B. A. Chapin as president.

BALTIMORE, MD.—The Chesapeake & Potomac Telephone Company will expend $750,000 in improving its entire system.

BALTIMORE, MD.—The Hughes Telephone Mfg. Company has recently issued bonds to the extent of $50,000 for the purpose of developing the capacity of its plant.

PITTSFIELD, MASS.—The New York Central Railroad is installing a complete system of telephones in the yard in this city and at the Junction, which will connect the switch houses and terminals with the freight depot.

YPSILANTI, MICH.—The Washtenaw Home Telephone Company has been refused a franchise here.

LAKE CITY, MICH.—The Missaukee Telephone Company has been incorporated with a capital stock of $5000.

MENOMINEE, MICH.—The Central Telephone Exchange has just completed the installation of its new system. There are 700 telephones connected and the exchange cost $24,000.

WAYNE, MICH.—The People's Telephone Company at its annual meeting elected the following officers: President, Joseph Waltz; vice-president, John Chamberlain; secretary and treasurer, F. L. Edwards.

KALAMAZOO, MICH.—The Citizens' Telephone Company has perfected its re-organization, with F. P. Rowe, president; R. C. Packard, secretary and general manager; E. W. Bowman, treasurer. W. Wheeler, Chicago, is constructing engineer. The company is capitalized at $250,000, and will erect an extensive independent system in Kalamazoo with branch exchanges in a number of surrounding towns.

GRAND RAPIDS, MICH.—The new Strowger automatic telephone plant of the Citizens' Telephone Company is about completed. All that remains to be done is the completion of the work of cutting in and testing. The company expects to switch to the automatic system before Feb. 1, with about 4500 subscribers. The services of about 100 telephone girls will no longer be required, but the company will retain probably 40 employees in the long distance and information departments.

WASECA, MINN.—The Tri-State Telephone Company intends to build a line from here to Albert Lea.

REDWOOD FALLS, MINN.—The Redwood County Rural Telephone Company is constructing an extension to its line from here to Morton.

LA PLATA, MO.—The La Plata & Western Telephone Company has been incorporated with a capital stock of $1500. Directors: J. A. Dusley and others.

ST. CHARLES, MO.—The Kinloch Telephone Company is constructing a line from this city to Portage des Sioux and West Alton, this county. The line will be in operation by Jan. 15.

HANNIBAL, MO.—Articles of incorporation for the Hannibal and Ralls County Telephone Company have been filed. The incorporators are J. I. Davidson, Dr. W. L. Birney and I. H. Harper.

GALLATIN, MO.—The Crab Orchard Telephone Company, of Gallatin, has been incorporated; capital stock, $2008, all paid. Incorporators: W. E. Hathaway, Hiram Burns, W. P. Heysey, E. E. Duffy, E. H. Cravens, M. A. Shipley, John O. Heaston, W. T. Roper and others.

LIVINGSTON, MONT.—The Rocky Mountain Bell Telephone Company intends to construct telephone lines up the Yellowstone and Shield River valleys. The lines will be built from Livingston.

BASSETT, NEB.—At a special meeting of the stockholders of the Bassett and Springview Telephone Company the capital stock was increased to $25,000. This increase is to provide for new extensions which are projected in Rock, Brown, Holt and Loup Counties next spring.

ORD, NEB.—The Valley County Telephone Company has made a move to buy out the independent exchanges at Ord and North Loup and reorganize as a mutual company. The business men of both places are encouraging the movement as it will give valuable communications with both Custer and Garfield Counties and make a system which will embrace about 1000 telephones in the home county.

HILLSBOROUGH, N. J.—The Hillsborough & Montgomery Telephone Company, Hillsborough, Somerset County, has been incorporated; capital, $125,000. Incorporators: Peter A. Garretson, William C. Hendrickson, William M. Frankhouser, Louis E. Opie, A. J. Van Nuns, Belle Meade, David J. Smith and Jacob C. Gulick.

MANCHESTER, N. Y.—The Clifton Springs Telephone Company is extending its line north of Gypsum.

NORTH WOLCOTT, N. Y.—The North Wolcott Telephone Company is the name of a new company being formed here by N. J. Field, J. N. Robertson and others.

SHERMAN, N. Y.—The Independent Telephone Clearing Association has been incorporated with a capital stock of $5000. Directors: H. H. Corbett, W. H. Homewood and others.

CHARLOTTE, N. C.—It is reported that a deal is on foot for the purchase of the extensive interests of the South Carolina Long Distance Telephone Company by the Bell Company. This move is said to be a result of the failure of the American Contracting Company which has been financing the South Carolina Long Distance Company. It is understood that the Bell Company will make many improvements on the local system in the city of Columbia where the Long Distance Company has large holdings.

FARGO, N. D.—The Hunter Telephone Company has purchased the private wire from Blanchard to Amenia and will build one to Gradin.

SHELDON, N. D.—The Northwestern telephone line is to be extended from Englevale to Fort Ransom.

MT. VICTORY, OHIO.—The Mt. Victory Telephone Company has been incorporated with a capital stock of $25,000.

NELSONVILLE, OHIO.—The York Telephone Company has been incorporated with a capital of $1000. Directors: W. S. Follett, E. R. White and others.

OTTAWA, OHIO.—The village council has refused a franchise to the Central Union Telephone Company (Bell) which has been endeavoring to get into Ottawa.

MUSCOGEE, I. T.—The North American Telephone Company has completed the Denison-Wagoner division of its line and cut in on the local exchanges here. This company is covering Indian Territory and Oklahoma with its long-distance toll lines and already has connection with 157 exchanges in North Texas, Oklahoma and Indian Territory. The line is being built as rapidly as possible north to Joplin, Mo., where it will make direct communication with Kansas City and St. Louis.

TORONTO, ONT.—The Canadian Telegraph & Telephone Company is about to make application to the civic authorities of Toronto for permission to do business in this city. This company, which will have exchange connection with all the independent telephone companies of the United States and which also has the right to construct long distance lines from the Atlantic to the Pacific, intimates that it is prepared to give service at a rate much lower than that now charged in Toronto.

OTTAWA, ONT.—The city of Ottawa has received another independent telephone offer. This now comes from H. Waddington, president of the Stark Electrical System, of Toronto, a new corporation. The company proposes to give a combined service of telephone, electric light and power over one circuit. Arrangements have just been completed to install a plant in the town of Toronto Junction, Ont., and Ottawa is asked to await the result. The company claims that telephones will be given at 25 per cent of the present cost, and electric light at two-thirds the present cost. The company will make Ottawa an offer for an area within a radius of 15 miles at the following rates: Telephones $6 per annum and one cent for each out-going call, the maximum cost to be $15 per year for house and $36 for business telephones.

ELECTRIC LIGHT AND POWER.

OPELIKA, ALA.—The Alabama Electric Light & Power Company has been incorporated by C. G. Abercrombie and H. C. Davidson, both of Montgomery, to furnish electric lights and power for lighting Opelika and other towns and cities in this state and the state of Georgia. Capital, $50,000.

FLORENCE, COL.—It is stated that another power-house for supplying power to the mines of Cripple Creek and the traction company at Pueblo will be built by the Woods Investment Company on upper Beaver Creek in the vicinity of Pike's Peak.

DENVER, COL.—L. B. Curtis, of Denver, constructing engineer of the Routt County Electric Light & Power Company, writes that plans and specifications for the electric plant are being prepared and bids for construction will be received about April 1. The probable cost of plant will be $60,000.

LITTLETON, COL.—The Canon Power Company has been incorporated with a capital of $500,000 to utilize the waters of Bear Creek for generating electrical power to supply light to Morrison, Golden, Ft. Logan, Littleton, Englewood and parts of Denver. Incorporators: Albert B. Sanford, Arthur K. Smith and Geo. J. Bucher. The plant will be near Littleton.

WASHINGTON, D. C.—The Senate Committee on Pacific Islands and Porto Rico has made a favorable report on the bill to approve a special act of Legislature of Hawaii providing for the manufacture and distribution of electric light and power on the island of Oahu.

COLUMBUS, GA.—The Columbus Power Company has ordered machinery for developing additional water power which will bring the total up to 9000-hp. The new machinery will arrive in about four months time.

SHELBYVILLE, ILL.—The Shelbyville Water, Heat & Light Company has been incorporated with a capital of $50,000. Incorporators: C. S. Scovil, W. H. Beem, W. S. Middlesworth and others.

BLOOMINGTON, ILL.—The Consumers' Heat & Electric Company has purchased a 400-kw, 220-volt direct-connected General Electric generator, and a 600-hp Allis-Chalmers Corliss engine. This new equipment is now being installed in the company's new plant.

JEFFERSONVILLE, IND.—The United Gas & Electric Company has been granted a franchise in this city. The ordinance provides that the city shall pay $60 each a year for 110 or more arc lights for street lighting and settle an old bill of about $6500, on a basis of $46.50 for the lights that have been in service since Oct. 9, 1902.

SOUTH BEND, IND.—Contracts for the water power and electrical machinery for the power plant of the Oliver Chilled Plow Works are reported to have been awarded as follows: Westinghouse Electric & Mfg. Company, of Pittsburg, Pa., three 500-kw alternating current generators, switchboard, etc.; Dodge Mfg. Company, of Mishawaka, harness for 12 water wheels, and to the Jas. Leffel Company, of Springfield, Ohio, water wheels, turbines and governors.

RICHMOND, IND.—The local electric light rate war is not only arousing much interest here, but in other cities of the state. In some cities the local experience is held up as an indication of the troubles that municipal lighting is sure to bring. Mayor Zimmerman and other city officers are firm, however, in their declaration that the private company cannot "oust" the city from the business. The fight between the Light, Heat & Power Company and the municipal plant is sure to be the issue in the next campaign. Councilmen standing for re-election will be forced to stand for or against the sale of the municipal plant. On this issue an appeal has been made to the people. Mayor Zimmerman said: "If the city plant never does better than meet expenses it will have done a great good in bringing the price of electric lighting down to a reasonable basis. We would not have cheap electric lighting to-day but for the city plant, and we will have it no longer if the city is sold out to the private company."

GRAETTINGER, IA.—The citizens are planning to put in a $10,000 electric light plant.

CHARLESTOWN, KY.—A franchise for an electric light plant has been granted to Clarence R. Hay and work will be started at once. The town will take 20 arc lights at $48 per annum on a moonlight scale.

BELFAST, ME.—L. G. Vose, general manager Belfast Gas & Electric Company, writes that it is proposed to construct a complete water power plant at Hiramdale Falls.

IPSWICH, MASS.—Notes for $5000 for a lighting plant will be issued by the treasurer and selectmen.

DULUTH, MINN.—At the coming election a proposition to issue $50,000 water and light extension bonds will be voted on.

WINONA, MISS.—The Winona Water, Sewerage, Ice & Light Company, of Winona, has been incorporated with a capital of $250,000, with Claude R. Kelso, Robt. A. Allison and Arthur Blake, as incorporators.

COLUMBIA, MO.—The City Council has decided to purchase the water and light plant of the Colombia Water & Light Company.

RED LODGE, MONT.—It is reported that the Electric Light Company will install a new plant in the spring.

LITTLETON, N. H.—This town is establishing an electric light plant of its own. The equipment will include two 30-inch turbines which are being supplied by J. & W. Jolly, of Holyoke, Mass.

SODUS, N. Y.—This village is contemplating the erection of a $25,000 electric light plant. Mr. A. B. Williams can give information.

FRANKLIN, OHIO.—The Franklin Electric Light Company is installing a new engine, generator and boiler.

OAK HARBOR, OHIO.—The Oak Harbor Electric Company has been organized by C. H. Graves, Geo. Mylander, S. Mylander and E. B. Graves.

MECHANICSBURG, OHIO.—T. J. Long, of the Mechanicsburg Light & Power Company, writes that it is proposed to construct an electric light plant at a cost of about $8000.

BUCYRUS, OHIO.—The Bucyrus Electric Light Company is erecting a new lighting plant and the equipment has been received. It is expected the plant will be in operation in about 30 days.

TOLEDO, OHIO.—The board of public works has decided to install electrical power on the swing of the Cherry Street bridge and bids will be asked for on the motors and other necessary equipment.

CLEVELAND, OHIO.—Electric lighting companies throughout the State have joined hands in a movement to secure the repeal of the law passed by the last Ohio Legislature relieving the railway companies from maintaining arc lights at railroad crossings.

COLUMBUS, OHIO.—The Indianola Heating & Lighting Company has given a blanket mortgage for $1,000,000 to the Guarantee Title & Trust Company, of Cleveland. The company is erecting a large heating and lighting plant and the mortgage covers all the property.

TOLEDO, OHIO.—The Fisher Electric Company, of Toledo, has received a contract for installing an electric lighting plant at Capac, St. Clair County, Mich. The equipment will include a 150-hp horizontal automatic engine, a single phase, 60 cycle, 2300-volt, 75-kw lighting generator, together with necessary switchboard apparatus. The company commenced business about 14 months ago and has filled a number of contracts of this character.

GETTYSBURG, PA.—Adam Ertter is interested in the construction of an electric light plant.

COALPORT, PA.—The Coalport Light, Heat & Power Company, of Coalport, has been incorporated with a capital of $5000.

STEWARTSTOWN, PA.—The Deer Creek Water & Water Power Company, of Stewartstown, has been incorporated with a capital of $6000.

NORTHUMBERLAND, PA.—The Northumberland Electric Light, Heat & Power Company, of Northumberland, has been incorporated with a capital of $5000.

YANKTON, S. D.—Mr. Edmunds, proprietor of the electric light plant, has offered the City Council to sell his plant, exclusive of tools and office fixtures, for $15,000.

HENRIETTA, TEX.—The City Council has granted a franchise to the Brower Lighting Company to establish an electric light system through the town.

SAN ANTONIO, TEX.—The election to vote on the proposition to issue $200,000 of bonds for the construction of a municipal electric light and power plant was held on Dec. 19 and resulted in overwhelming defeat.

WAXAHACHIE, TEX.—The Waxahachie Gas & Electric Company has been organized here with a capital stock of $100,000 for the purpose of installing an electric light and power plant and a gas plant. The incorporators of the company are J. F. Strickland, Osce Goodwin, W. C. Ross and M. B. Templeton, all of Waxahachie, and R. C. Vickery, of Fort Worth.

SALT LAKE CITY, UTAH.—Some time ago a protest was made by citizens against the alleged inferior service rendered by the Utah Light & Power Company, which resulted in the appointment of a committee to investigate the matter. The committee has submitted its report which states, in substance, that while the service is far from what could be desired, on account of a lack of modern equipment for regulating the electrical current, it was no better than had been represented in the protest. The committee, however, announced that the electric light company had expended during the present year $520,000 in the improvement of its system and that of this amount $170,000 had been spent on the Salt Lake service. The report concludes with the statement that the Utah Light & Power Company is doing everything in its power to remedy the conditions at present prevailing. R. S. Campbell, manager of the lighting company, assured the committee that a large sum would be expended during the present year in improving the system.

COLUMBIA CITY, WASH.—The Town Council has granted a franchise to the Snoqualmie Falls Power Company to install an electric light and power station in Columbia.

WHEELING, W. VA.—The County Commissioners have decided to install an electric light plant at the County Infirmary at East Richmond.

COLEMAN, ALBERTA, CAN.—The International Coal & Coke Company has let contracts for the equipment to be installed in its coke works. The Westinghouse Elec & Mfg. Company will furnish the electrical equipment, and the Phœnix Iron Works, of Meadville, Pa., the engines.

CITY OF MEXICO, MEX.—The Mexican Government has granted a concession to Filiberto Romero for the establishment of an electric power plant on the River Tancoco, at a place called Chorro Grande, in the state of Vera Cruz.

MATEHUALA, MEX.—James Kilton has obtained the contract to supply this city with electric lights and power and to establish and operate a system of water works here. He has already begun the development of extensive plans which include the construction of four electric generating stations which are to obtain their initial power from water which is to be piped from large natural springs situated on the top of a mountain, situated at a height of 1000 feet above this city and 22 miles distant. The water of these springs will be piped to the power stations and thence conveyed to this city and used to supply the mains of the water works system. Engineers have examined and made favorable reports on the project and surveys are now being made preparatory to beginning construction work. It is proposed to not only supply the city with electric lights and power, but to also furnish power for operating the numerous mines which are situated in this district. A telephone system is being established here. W. H. Smith is interested.

OTTAWA, ONT.—A conference has taken place between the Ontario government and those interested in the development of the water power on Kettle Falls, at Fort Frances, Ont., Minneapolis men have already secured the rights on the United States side, and have also a preference on the rights on the Canadian side. The Ontario government insists on the condition that one-half of the power developed, which is about 5000 horse power, shall be used exclusively on the Canadian side. The conference closed without reaching any agreement.

THE ELECTRIC RAILWAY.

COLUMBUS, IND.—The citizens of Wayne Township have voted a 2 per cent subsidy tax for the Indiana Central Interurban Railway, which will extend from Columbus to Seymour. The tax will amount to $25,000.

KOKOMO, IND.—The Kokomo, Marion & Western Traction Company has let the contract for the equipment of a new power station in this city. It is said the machinery will cost $250,000, and that the buildings and power plant complete will cost $400,000. The road is almost completed to Marion.

RICHMOND, IND.—The Wayne County Commissioners have granted a franchise to the Columbus, Greensburg & Richmond Traction Company through the county and to cross the public highways. The company has its own right of way. The franchise provides for the building of the line within two years.

EVANSVILLE, IND.—The officials of the Evansville, Boonville & Rockport Interurban Railway Company have made arrangements with the Interurban Construction Company, of Indianapolis, to finance and construct the road. The engineers of the two companies are drawing plans and specifications, and when completed, contracts will be signed. Charles E. Maley, Claude Maley, Daniel Wertz and William Threlkeld, of Evansville, are the principal members of the company.

INDIANAPOLIS, IND.—The recent order of the Board of Public Works requiring the interurban cars entering this city to stop at street crossings wherever signaled and take on and let off city passengers has aroused a storm of objection by the interurban managers. They insist that it is an imposition on the interurban passengers to be crowded by city passengers, and that it is a great waste of time. President Henry, of the Indianapolis & Cincinnati Interurban line, suggested that the Board has full power under its contract with the City Street Car Company to compel the latter to give all the service that the demands of the city traffic require. Mr. Henry thinks there should be no necessity for using interurban cars in city service. The Board, however, renewed its order and threatens to punish the companies found guilty of refusing to take on city passengers.

LEWISTON, ME.—Fire, a few days ago, destroyed the car house and 35 cars of the Lewiston, Brunswick & Bath Street Railway, involving a loss of about $50,000.

AMHERST, MASS.—The Amherst & Sunderland Street Railway Company has petitioned the Railroad Commissioners for authority to issue bonds to the amount of $117,000 for the purpose of retiring outstanding bonds to the amount of $51,500 of funding so much of the company's floating indebtedness as may have been incurred for construction and equipment, and for the purchase of additional real and personal estate.

TRAVERSE CITY, MICH.—The Traverse City & Peninsula Railway Company has been organized at Traverse City, with a capital stock of $500,000, for the purpose of building an electric railway from Traverse City to Old Mission and the intervening summer resort and fruit growing country. The officers of the company are L. K. Gibbs, president; W. P. Crotser, of Traverse City, secretary; J. O. Crotser, of Kingsley, treasurer.

SPRINGFIELD, OHIO.—The Springfield & Washington C. H. Traction Company has been granted an extension of time to Jan. 1, 1905, in which to construct its line. The promoters claim they have succeeded in financing the project, and that work will be started within a few weeks.

MANSFIELD, OHIO.—The promoters of the Mansfield & Wooster Traction Company assert that arrangements have been completed for financing the project, and that work of construction will start in the spring. The headquarters of the company are in Shreve.

CLEVELAND, OHIO.—The Lake Shore Electric Railway Company has just placed contracts with the C. & G. Cooper Company, Mt. Vernon, Ohio, for a 1200-hp cross-compound condensing engine, and with the General Electric Company for a 1500-kw alternating-current generator, together with switchboards and equipment for two sub-stations.

FINDLAY, OHIO.—The Buckeye Traction Company has been organized by local people to build an electric railway between Toledo and Columbus by way of Fostoria, Carey, Upper Sandusky and Marion. A line from Fostoria to Marion would complete through connection, as roads are already in operation from Toledo to Fostoria, and from Marion to Columbus. The capital stock of the new company will be $1,000,000.

CHARDON, OHIO.—W. C. Warner, Monroe Warner and Andrew Warner, of Chardon, are the chief promoters of the proposed Cleveland, Chardon & Meadville Railroad Company, which has been incorporated to build an electric railway from Chardon to Meadville, Pa. The road will touch a number of towns that at present are isolated. A private right of way has been secured over a greater portion of the route.

SALEM, OHIO.—The Stark Electric Railway Company, which is completing its line into Salem, is negotiating for the purchase of the property of the Salem Electric Railway Company. The city system includes a power house and about 4 miles of road commanding the most desirable entrance to the town. The Salem people, it is said, ask $100,000 for the property, which is considered too high by the prospective purchasers.

COLUMBUS, OHIO.—Samuel W. Bennett, special counsel to the State Attorney-General, has rendered the opinion that stockholders of railroads, street railroads, electric light, gas, waterworks and other so-called quasi-public corporations are not exempt from double liability on their stock for the debts of these corporations by the recent constitutional amendment. It is claimed that the amendment applies only to private corporations. A number of such corporations have recently taken out charters in Ohio, under the impression that only a single liability could be enforced in the future under the amendment.

UNIONTOWN, PA.—The building of an electric railway from Fairchance to Point Marion, a distance of 13 miles, has been decided upon by a company including O. W. Kennedy, general manager of the H. C. Frick Coke Company, of Uniontown; John W. Byers, Lee B. and Owen H. Brownfield and others. A charter will be applied for, and the company will probably be capitalized at $250,000.

ERIE, PA.—At the second annual meeting of the stockholders of the Erie, Cambridge, Union & Corry Railway Company, the following officers were elected: F. A. Gibson, of Erie, president; John Doll, of Erie, secretary; F. L. Hoskins, of Edinboro, treasurer. Arrangements were made for active construction work to commence in the early spring. All contracts have been let for material and equipment. The capital of the company is $1,000,000. Axel H. Engstrom, of Philadelphia, is consulting engineer.

HARRISBURG, PA.—Application will be made at the State Department Dec. 31 for a charter for the West Penn Railway Company, which will be a merger of the electric lighting and power plants in the coke regions and the Pittsburg, McKeesport & Connellsville Electric Railway Company. The incorporators will be William S. Kuhn, Jacob V. Van Wagener, John I. Cockburn, Jesse H. Purdy and Jerome Hill, Jr. The capital stock will be merely nominal until the merger is completed, when it will be increased to more than $5,000,000. The West Penn Railway & Lighting Company has been in control of the electric lighting and power plants in Westmoreland and Fayette Counties. The lighting companies that will be included in the merger are located at Connellsville, Dawson, Irwin, Jeannette, Manor, Greensburg, Mt. Pleasant, Tars, New Haven, Uniontown, Fairchance and Masontown. In a number of cases the old stations have been abandoned, power now being supplied to the towns from the new power house, which is located a short distance above New Haven on the Youghiogheny River. Those interested in the company include: W. S. Kuhn, who is the general manager; J. S. Kuhn, E. C. Converse, M. K. Salsbury, W. S. Graham and J. B. Van Wagener. It is probable that W. S. Kuhn will be at the head of the new company. The organization will be completed by placing the lighting and power companies in one company and the railways in another, with the West Penn Railways Company as the holding concern.

WESTERLY, R. I.—The Westerly & Hopkinton Street Railway Company has purchased the control of the Pawtucket Valley Street Railway Company and has elected the following officers: William Hoxsey, president; Frank P. Sheldon, vice-president; J. O. Sweet, secretary and treasurer. The Westerly Gas & Electric Company (common stock is $50,000; preferred, $7500) is under contract of purchase, and will be acquired in a short time. In January the several properties are to be consolidated under the laws of Rhode Island as the Westerly Railway & Lighting Company. Capitalization, $200,000 common stock, $200,000 5 per cent cumulative preferred stock and $400,000 of 5 per cent thirty-year bonds. The management expects to extend the road from Westerly to Hopkinton in the spring.

JACKSON CITY, TENN.—The Johnson City Traction Company has completed its line to New Street, and is now running cars down Watauga Avenue. It now has about 2½ miles of track, and is expecting in the near future to extend the track to the Carnegie Hotel.

NASHVILLE, TENN.—The Silver Interurban Railway Company has just been incorporated here, with a capital stock of $250,000, which will later be increased to $1,500,000. The company will build an electric railway from Nashville to Lewisburg, and will probably extend the line to Huntsville, Ala.

BROWNSVILLE, TENN.—The Shelby County Traction Company will build an electric railway in the near future from Brownsville to Dyersburg, a distance of about 32 miles. The road will be used for both freight and passengers. This company also proposes to construct lines from Memphis to Colliersville and to Bolivar, Tenn. Judge T. J. Latham, of Memphis, is among those interested.

HOUSTON, TEX.—The City Council has passed the ordinance granting a franchise to the Houston & Galveston Interurban Railway Company. The line will be 48 miles in length, the shortest rail route between Houston and Galveston.

PORT ARTHUR, TEX.—The company which has been organized here through the efforts of John W. Gates for the construction and operation of an electric railway from this place to Taylor's Bayou will soon file its charter for record in the secretary of state's office at Austin. It is stated that Mr. Gates owns a controlling interest in the company. It is reported that the Beaumont & Sour Lake Construction Company will be awarded the contract for building the new line.

GALVESTON, TEX.—The Galveston City Railway Company will expend about $60,000 during the coming year for improvements. The original budget for the coming year embraced the proposed expenditure of $227,000 for extensions and improvements, but this sum has been cut down on account of the large amount that will be incurred in street paving due to the raising the grade of the city. Major R. B. Baer, president and general manager of the company, says that the company has expended the sum of $1,068,000 in rehabilitating the system and in improvements since the great storm which swept over the city three years ago.

FOND DU LAC, WIS.—The Fond du Lac & Eastern Railway Company seeks a franchise to build a line in this city and to sell power and light, and to build a power house.

WATERTOWN, WIS.—The Oconomowoc-Watertown Heat, Light & Power Company is seeking a franchise for an electric interurban line to run from Oconomowoc to Watertown, Lake Mills, Jefferson and probably Janesville.

TORONTO, ONT.—The Toronto Railway Company expects to have its new storage-battery plant in operation in three months. This battery is being installed solely to supply power to run the additional service given between 5 and 6.30 in the evening, and in the morning, if necessary. The company has had to increase its services in the morning and evening during the past year on account of the big increase in the suburban population of the city. Many people who removed to the Beaches to spend the summer are wintering there, and an increased number of those employed in the city are residing in East Toronto, Mimico, Eglinton and Toronto Junction.

NEW INDUSTRIAL COMPANIES.

THE MUTUAL STOCK & TELEGRAPH COMPANY, Buffalo, N. Y.; capital, $100,000. Directors: D. F. Harrington, William Walker and Peter S. Wering, Buffalo.

THE INTERMITTENT CURRENT CLEANING COMPANY, New York; capital, $100,000. Directors: G. G. Power, W. H. Donnally, and Frank Hendrick, New York.

THE VEHICLE SPECIALTY COMPANY, of Jersey City, has been incorporated; capital, $50,000. Incorporators: Le Roy S. Louis, William D. Johnston and Louis G. Morton.

THE VESUVIUS BATTERY COMPANY, New York, to manufacture electric batteries; capital, $10,000. Directors: S. G. Whiton, A. S. Apgar and L. H. Bigelow, New York.

BAKER & COMPANY, Newark, N. J., to refine ores, platinum and other materials; capital, $430,000. Incorporators: Cyrus O. Baker, Charles W. Baker, Henry R. Bond, Jr., and Edward A. Colby.

THE ELECTRIC UTILITIES COMPANY, of Mineola, Nassau County, N. Y., has been incorporated with a capital of $1,000,000. The directors are Andrew R. McLaren, Alfred H. Townely, George T. Van Valkenburgh, John D. Mason and Thomas J. Snee, of New York City.

THE DEAN ELECTRIC COMPANY has been incorporated under the laws of the State of Ohio and will erect a modern factory at Elyria, Ohio. The capital stock is $300,000. Incorporators: Samuel B. Rawson, I. H. Griswold, T. M. Brush, A. E. Barker and W. W. Dean.

THE KIRKLAND ELECTRIC COMPANY, of Kirkland, Oneida County, N. Y., has been incorporated; capital, $100,000. Directors: J. F. Wood, Clinton; G. L. Wood and H. B. Sweet, Utica. The directors have organized as follows: President, Henry W. Roberts, of Clinton; vice-president, George L. Wood, of Utica; secretary, James F. Wood, of Clinton; treasurer, Herbert Allen, of Clinton. Horace P. Sweet, of Utica, has been engaged as engineer.

OBITUARY.

CAPT. EDWARD B. IVES, Signal Corps, who had been on duty in the office of the Chief Signal Officer at the War Department for some time past, died in Washington on Dec. 29 from a complication of diseases. He was born in the District of Columbia, but was appointed to the Military Academy from New York in July, 1874.

MR. R. C. VILAS.—Royal Cooper Vilas, president of the Pyle National Electric Headlight Company, died last week in Chicago, aged 61 years. Mr. Vilas was born in Ogdensburg, N. Y. He was at one time General Freight Traffic Manager of the Erie Railroad in New York, and president of the New York Air Brake Company, of New York City.

H. T. RICHARDS.—It is with deep regret that we announce the death of Herbert T. Richards, secretary of the Safety Insulated Wire & Cable Company, which occurred on Dec. 26, last. Deceased was about 42 years of age, and was well known in electrical circles. His death was due to a surgical operation involving the kidneys, from the shock of which he did not rally.

PERSONAL.

MR. JOHN MATHER, of Wayne, Pa., has become general manager of the Merion & Radnor, Pa., Gas & Electric Company, as successor to Mr. W. E. Barrett.

MR. JOSEPH V. KUNZE, manager of the New York offices, 143 Liberty Street, of the Pelton Water Wheel Company, has returned from a trip to Mexico.

MR. MORRIS MEAD, well known for many years past as the city electrician of Pittsburgh, Pa., has retired and will hereafter enjoy his *otium cum dig.* with a pension.

MR. R. H. MANSON has been placed for the time being in charge of the sales department of the Kellogg Switchboard & Supply Company in place of Mr. A. E. Barker, resigned.

MR. ERICH BROCKHAUS, chief engineer of the Siemens-Halske Company, of Berlin, is on a visit to this country, like so many other prominent officers of the company before him.

MR. E. A. CHAPEL, formerly of the electrical department of the Chelsea, Mass., Gas Light Company, has been appointed superintendent of the Nantucket, Mass., Gas & Electric Company.

MR. THOMAS HANKEN has become president of the United Gas & Electric Company, of Dover, N. H., in place of Mr. H. L. Shepard. Mr. G. W. Welch has been elected treasurer.

MR. W. F. HOWE.—The ELECTRICAL WORLD & ENGINEER has a communication from this gentleman, but before using it would like to be furnished by him with some data of identification.

MR. C. E. REYNOLDS, superintendent of the mechanical department of the Rochester Gas & Electric Company, has resigned after 18 years' service to go to Boston. His associates gave him a diamond pin on leaving, as a mark of appreciation.

MR. JOHN F. SKIRROW, an able young man and one of the contributors to this journal, has been promoted to the position of assistant electrical engineer of the Postal Telegraph Cable Company. He was born in England in 1869 and has been with the Postal since 1890.

MR. ARTHUR J. HERSCHMANN, M. E., who has been associated with the Adams Express Company for five years past in New York City, has taken an office at 45 Broadway, and will make a specialty of heating, lighting and ventilating plants, their installation and supervision.

PROF GUIDO GRASSI, of the Turin, Italy, Museo Industrialo, will make a visit to this country next fall to be in attendance at the International Electrical Congress at St. Louis. Prof. Grassi conducts at the Turin Museo the course in electrical science developed by the late Professor Ferraris.

MR. EDWARD W. PARKER has issued for the U. S. Geological Survey a report on the production of gas, coke, tar and ammonia at gas works in 1902, in this country. The figures of 533 companies making gas from coal in 44 states and territories are included in this valuable document.

MR. P. G. GOSSLER, electrical engineer, etc., of the Montreal Light, Heat & Power Company, has resigned his important and responsible position there in order to become associated with the well-known engineering firm of J. G. White & Company, to which he will prove a valuable acquisition.

MR. W. G. ROSS, of Montreal, has resigned as second vice-president of the Montreal Light, Heat & Power Company, and has become managing director of the Montreal Street Railway. Mr. Rodolphe Forget, who resigned from the first vice-presidency of the power company to make way for Mr. McLea Walbank, was appointed to succeed Mr. Ross.

MR. J. T. OAKLEY, a well known leader in Democratic politics, has been appointed under the Tammany regime as Commissioner of the Department of Gas, Water and Electricity of Greater New York, succeeding Col. R. Munroe, who is also a member of the Democratic party, but conducted his department on very independent lines under Mayor Low.

MR. WILLIAM MACKENZIE, of Toronto, Can., who is president of the Saô Paulo Tramway, Light & Power Company, Limited, is now on a visit to New York. The company operates an extensive system in Saô Paulo, Brazil, which is about to be considerably extended. Mr. Mackenzie is at the Waldorf-Astoria and at the Saô Paulo offices, 29 Broadway.

M. CURIE has declined the red ribbon of the Legion of Honor and gives his reasons. "I don't like decorations," he says. "The institution is bad. Many people whom I esteem have them, but I don't want any. I am of the opinion that the hope of receiving decorations is not necessary as an incitement to acts of devotion or courage, as is commonly supposed."

MR. GEORGE W. EDGE, recently with Stanley & Patterson, has taken a position with the Trumbull Electric Mfg. Company, of Plainville, Conn., and will represent it through the middle west and eastern states. Mr. Edge will call on his old friends in his new capacity. Mr. Frank Trumbull has also accepted a position with the Trumbull Company and will travel in the states west of the Mississippi River and in the southern states.

MR. JOSPER F. KELLER, now manager of the New England Telephone & Telegraph Company will become second vice-president of that company this year. Francis A. Houston, now general counsel, will succeed Mr. Keller as general manager. Matt. B. Jones, of Powers, Hall & Jones, will succeed Mr. Houston as general counsel. Mr. Jones will hereafter give his whole attention to the New England Telephone & Telegraph Company.

MR. P. N. NUNN, chief engineer of the Telluride Company, Colorado, is referred to in the following dispatch from Salt Lake City of January 1: Announcement was made to-day that a new and unique school of electrical engineering would be founded during the current year by Mr. Nunn, of Telluride, Col. It is the intention of the founder to give a full course in mechanical and electrical engineering at Provo Canon, Utah, keeping the students actually employed and under pay during the period of their course.

PROF. S. P. THOMPSON, F. R. S., has just issued, in admirable pamphlet form, his admirable "note" on Gilbert, prepared for the three hundredth anniversary of the death of Dr. Gilbert, December 10, in connection with which event the British Institution of Electrical Engineers has just presented to the corporation of Colchester, where he was born and where he is buried, an interesting picture of Mr. A. Acland Hunt. The painting measures 6 by 4 feet and represents Gilbert expounding his magnetic discoveries and ideas to Queen Elizabeth.

MR. W. S. MONTGOMERY, who has for the past five years been connected with the Conover Condenser Manufacturing Company, of Jersey City, as secretary and sales manager, has severed his connection with that company to assume the management of the Payne Engineering Company of New York City, selling agent of the Payne Company, of Elmira, N. Y., builder of simple and compound automatic engines. On the same date, the Payne Engineering Company will remove to new offices in the Havemeyer Building, No. 26 Cortlandt St., New York.

MR. J. H. ROBINSON, of the U. S. Military Telegraph Corps, who made application as such for membership in the Society of the Army of the Cumberland has been advised by Gen. H. V. Boynton, president of the organization that the executive committee of that body is unanimously in favor of recognizing the claims of members of the Corps who served with the army, to be admitted to membership in the society. Every one must feel that this decision is right, and that the gallant telegraphers who went under fire just as freely as the rank and file are entitled justly to all the honors that can come to them.

MR. CHARLES JOHNS, JR.—A St. Thomas, Ont., newspaper says: "The first year's working of the Street Railway as a municipal service has resulted in a practical balancing of accounts which, in view of the fact that the system has been transformed into an up-to-date one, is considerably satisfactory. The total number of passengers carried was 359,190 and the total received for fares was $13,934.52, showing the average fare to have been 3.977 cents. The actual receipts were $14,603.35, only $136.43 less than the expenditure." It is interesting to learn that a student of the International Correspondence Schools, Scranton, Pa., Mr. Charles Johns, Jr., is manager of the St. Thomas Street Railway. He enrolled with the I. C. S. in June, 1899, at the age of 23, while employed as a machinist.

LEGAL.

MUNICIPAL PLANTS IN NORTH CAROLINA.—The Supreme Court of North Carolina has just handed down an opinion of importance to the effect that for a city to buy or establish a plant for light or water is a necessary expense and therefore does not require a vote of the people.

DUTY ON SUBMARINE CABLE.—Judge Henderson M. Somerville, of the Board of United States General Appraisers, administered a criticism to the Commercial Pacific Cable Company in overruling its claim for free entry for the cable from Hawaii to the United States, which was brought to Honolulu from England. The claim was made on the ground that the laying of the cable was a work of great public benefit. Such a claim, Judge Somerville said, might with propriety be made to Congress, but not to a judicial tribunal, which has no duty but to interpret the law as it finds it.

WATER POWER EMINENT DOMAIN.—A corporation authorized to develop and use the water power of a river and generate electric or other power, light, or heat, and utilize, transmit and distribute it for its own use or the use of other individuals or corporations, is held, in the case of Fallsburg Power & Manufacturing Company vs. Alexander, (61 Lawyers' Reports Annotated 129.) to be for a private use and not a public purpose, and therefore not entitled to exercise the right of eminent domain. Under statutory authority to exercise the right of eminent domain to secure land for a park, it is held, in the case of Laird vs. Pittsburg, (61 Lawyers' Reports Annotated 332,) that land needed for an addition to a free library building located in a public park may be taken.

GUTMANN RECORDING WATTMETER.—The order restraining the Electric Appliance Company, of Chicago, from selling or manufacturing the Gutmann recording wattmeter, which was granted on exparte application of the Westinghouse Electric & Mfg. Company, was continued on Dec. 29 by Judge Kohlsaat, of the United States Circuit Court, after a hearing. The action is based upon a suit brought in Philadelphia, in which the Sangamo Electric Company, of Springfield, Ill., the manufacturer of the Gutmann meter, intervened and became the defendants. In that action it was decided that the Gutmann meter was an infringement of the Tesla patents on the rotating magnetic field of the split phase type which belong to the Westinghouse Company. After an injunction was issued, it was discovered that the Sangamo Company was making a meter in which a slotted disc was substituted for the slotted cylinder before used. The Sangamo Company asked to have the injunction suspended as to this form, but this was refused. An application was made to have the Sangamo Company declared in contempt, but it was shown that at that time its factory was closed and no meters were being made. The contempt proceedings have not been decided. Later it was found that a large number of the disc meters had been sent to the Electric Appliance Company, of Chicago, which was selling them in the due course of business. The restraining order which has now been continued was then applied for.

EVANSVILLE WINS SUIT AGAINST THE CUMBERLAND.—Judge Anderson, of the United States Court, has dissolved the restraining order in the injunction suit brought by the Cumberland Telephone Company against the City of Evansville, Ind., to prevent the removal of its poles and wires from the streets. The court held that the city has a right to order the removal of poles, wires and other property of the company from the streets, and that the Cumberland has no right to operate in the city. It was shown that the Evansville Telephone Exchange was granted a franchise by the city in December, 1882. In July of the following year its business and property were purchased by the Cumberland Company and the latter company has carried on the business since that time. The telephone company alleged and declared that the right to the streets and alleys of the city, granted by the council in 1882 to the Evansville Telephone Exchange became the property of the Cumberland, together with all other property when the transfer was made. The answer of the city of Evansville was that it was outside the powers granted the original company to sell the property and business unless the franchise and ordinance under which it is operating specifically provides for such a sale and transfer. The court adopted this view and held that the Cumberland Company had no rights by the assignment of the Evansville Telephone Exchange and no rights under the ordinance of 1882 which it can ask the court to protect. The injunction was therefore dismissed for want of equity.

EXTRAORDINARY WASTE OF GAS.—The Kentucky Court of Appeals has reversed the judgment of the Meade Circuit Court in the case of the Calor Oil & Gas Company against W. C. McGehee, and affirmed it in the case of the Louisville Gas Company against the Kentucky Heating Company. The cases grew out of the efforts of the Louisville Gas Company to destroy the Meade County natural gas fields, from which the Kentucky Heating Company has for years been securing the gas which it furnishes to customers of Louisville. The Louisville Gas Company officers organized the Calor Oil & Gas Company, the stockholders being A. Hite Barrett, Rudolph Sneed and J. W. Speed. This company took over a number of leases of land made in the county. In this territory they erected what they called a lampblack factory. This factory was constructed with a stockade about it, inside of which no one was allowed to enter, and firearms were discharged to keep the neighbors away. When they began operations the Kentucky Heating Company had a gas pressure of sixty pounds, and in five months this was reduced to thirty pounds. The force of the lamp-black factory was two men, one for day and another for night. In five months the factory produced 300 pounds of lampblack, worth 4 cents a pound, and had consumed about 90,000,000 feet of the natural gas. The lampblack was never shipped away from the factory. On these facts the chancellor enjoined the operation of the lampblack factory, as violating the statutory laws against the wasting of natural gas. The retail price of natural gas for fuel in Louisville is 65 cents per thousand feet, making the value of the gas alleged to have been consumed in making $12 worth of lampblack $63,500.

Trade Notes.

PASS & SEYMOUR, Solvay, N. Y., have just placed on the market a new moulding receptacle. They are made in two styles to use with or without a shade holder. A postal card will bring samples and prices.

PITTSBURGH TRANSFORMER COMPANY, of Pittsburgh, Pa., issued a pretty Christmas folder with cuts of its large transformers and transformer tanks, giving an excellent idea of their solid and substantial construction.

"REASON WHY" is the title of a little folder, illustrated, sent out by the Pass & Seymour Company, Solvay, N. Y., giving reasons why its brass shell lamp sockets are held to be the best. The points are clearly and tersely made.

ROYAL ELECTRIC COMPANY, Peoria, Ill., has issued a neat calendar for 1904 showing one of its 100-kw 60 cycle Royal alternators of the inductor type, with exciter. A little information is given as to the features of the machine.

THE ORGAN POWER COMPANY, Hartford, Conn., has been developing some new devices for organ blowing with an alternating current motor and has issued a little brochure as to its Spencer organ blowing apparatus in general, water and electric.

JOSEPH T. RYERSON & SON, Milwaukee Avenue, Chicago, have just issued the sixth edition of Ryerson's Technical Library No. 4, describing the Continental boiler with Morison corrugated furnaces, and giving useful data and information regarding boiler design and construction.

"THE WHITE BULLETIN," copies of which have reached us, is a house journal issued by the White Sewing Machine Company, Cleveland, Ohio, in regard to its White steam automobiles which have made such a creditable record in the art. The little paper is quite up to the standard of the autos. and makes good reading.

YALE & TOWNE MFG. COMPANY has issued a neat little folder in regard to its chain blocks, this being the most recent printed matter given out by it in regard to the subject. It is called "Three Labor Savers" and deals with its triplex, duplex and differential blocks. Data are furnished as to each of these devices so economical of effort and expense. Copies can be obtained at 9-11-13 Murray Street, New York City.

KELLOGG.—The Kellogg Switchboard & Supply Company, of Chicago, has sent out a handsome new bulletin descriptive of its magneto or generator call telephones. This bulletin is the first of a series which will cover the entire product of the company in the telephone field. The arrangement of the matter and the descriptions and circuits have been carried out so as to constitute a popular text book for the small customer.

INCANDESCENT LAMP WALL CIRCULAR.—The General Electric Company has just issued from its lamp works at Harrison, N. J., a broad-sheet circular on heavy paper, devoted to its Edison lamps, on which is shown, full size, some 37 varieties with the data relative to each. This is a most striking and interesting circular and for the man who has the wall space a very nice thing to post up where it can be looked at every day with admiring eyes. It is very interesting to have thus brought to notice at one glance all the various makes and styles for different purposes, the lamps ranging from the largest to the smallest.

ALLIS-CHALMERS COMPANY, Milwaukee, Wis., has, as already announced in these columns, taken up the manufacture in this country of the Nurnberg gas engine. It is a four-cycle double-acting machine, for all power purposes, and is built in units of from 130 to 6000-hp. It operates with natural, producer, coke oven, blast furnace or illuminating gas. It has been brought to a state of perfection in which it will answer with absolute reliability the most exacting demands of power generation, and in the hands of such a standard concern will doubtless find a very large application in this country.

ELECTRIC APPLIANCE FUSES.—The latest thing in fuses is illustrated and described on page 241 in Electric Appliance Company's catalogue No. 20. The cartridge fuse is made in any capacity from 3 amperes to 30 amperes, and is listed in 125 and 250 volts. The company is now prepared to fill orders in the same capacity for 500 volt fuses. This McBride enclosed fuse is a regular cartridge with the fuse enclosed, and from each end of the cartridge is a soft copper wire which adapts the fuse for any style fuse connection on any cut-out, switch, panel-board, switchboard; or, in other words, it can be used wherever a fuse is desired, with absolute assurance that it will blow without an arc. They require no special cut-out, but fit the old style Sawyer-Mann cut-outs, Edison blocks and any switch connection.

MOISTURE FOR CIGARS.—In the manufacture of cigars the condition of the atmosphere within the building is of vital importance. The air must be kept moist and at a constant warm temperature both in the winter and summer season. For maintaining an even, moist and warm temperature the fan system is peculiarly adaptable, because the quantity and quality of the air is under absolute control and may be varied at will. Fresh air is drawn from outside the building by means of a fan, is circulated through a moistening chamber and, in the winter season, between coils of steam pipes enclosed in a fire-proof steel plate jacket, and delivered under pressure to the work rooms, through distributing ducts. The speed of the fan regulates the quantity of the air, the amount of steam varies its temperature and it is evident that the amount of water sprayed through the moistening chamber varies its moisture. The fan is driven by a direct connected engine whose exhaust steam may be used in the heating pipes, or in the summer time when heating is unnecessary it may be by-passed and utilized for other purposes. It is readily seen that with this system the expense of operating is very low as no heat is wasted. The three factories of the American Cigar Company at Tampa, Fla., are provided with the fan system for heating, ventilating and moistening, and the results reflect credit upon the B. F. Sturtevant Company, of Boston, Mass., whose apparatus and system were used.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED DECEMBER 29. 1903.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., N. Y.]

747,949. SIGNALING SYSTEM; William H. Dammond, Detroit, Mich. App. filed Nov. 5, 1902. Details.

747,967. TRAIN CONTROLLING AND SIGNALING SYSTEM; Fred P. Green, East Aurora, N. Y. App. filed Feb. 11, 1903. Mechanism by which the air brakes of a train can be operated from the train despatchers office, in case the train runs into a obstructed block.

747,968. ELECTRIC METER; Ludwig Gutmann, Peoria, Ill. App. filed Jan. 6, 1902. Improvements in the construction of a motor-meter in which the motor element has an armature consisting of a disk rotating in a conducting fluid through which current is conveyed to and from the armature, combined with a proper energizing field magnet.

748,053. BAR FOR COLLECTING ELECTRICITY FOR SECTIONAL CIRCUITS; Henry Dolter, Paris, France. App. filed Feb. 19, 1902. A contact shoe, parts of which are magnetic while other parts are non-magnetic, the collector being adapted to engage with studs in the roadbed and by the attraction of its magnetic parts close a circuit through the stud while by the non-attraction of other parrts, the circuit is opened before the contact is actually broken.

748,086. ELECTRIC FIRING GEAR FOR BREACH LOADING GUNS; John F. Meigs, Sigard A. S. Hammar and Leighton N. D. Mixsell, Bethlehem, Pa. App. filed Aug. 27, 1902. An apparatus whereby the contacts for firing the charge can be closed only when the other elements of the device are in proper position.

748,098. SYSTEM FOR CONTROLLING FLUID PRESSURE; Edward D. Priest, Schenectady, N. Y. App. filed May 21, 1903. The air pump on a train is cut out by the controller while the train is stationary, thus avoiding the annoyance to passengers of the operation of a pump, while the train is standing.

748,121. ELECTRIC ARC LAMP; Knut Tornberg, Medford, Mass. App. filed Nov. 1, 1902. The carbons arranged at right angles to each other are fed between two sets of grooved rollers which are driven by gearing.

748,123. ELECTRIC SWITCH; Isaac G. Waterman, Santa Barbara, Cal. App. filed Feb. 27, 1902. Details.

748,144. REGULATING DEVICE FOR ELECTRIC CIRCUITS; Malcolm H. Baker, East Liberty, Pa. App. filed June 26, 1902. A regulating reactance device having a regulating coil capable of relative inductive movement with respect to a magnetic core and an auxiliary coil, the two coils being arranged in series and being electrically opposed to each other.

748,145. METHOD OF REGULATING ELECTRIC CIRCUITS; Malcolm H. Baker, East Liberty, Pa. App. filed June 26, 1902. The method involved in the preceding apparatus patent.

748,146. CONSTANT POWER FACTOR REGULATING FOR ELECTRIC CIRCUITS; Malcolm H. Baker, East Liberty, Pa. App. filed June 28, 1902. A modification of the two preceding inventions.

748,147. METHOD OF REGULATING ELECTRIC CIRCUITS; Malcolm H. Baker, East Liberty, Pa. App. filed June 28, 1902. Same.

748,148. CUT-OUT FOR ARC LAMPS; Malcolm H. Baker, Pittsburg, Pa. App. filed Oct. 30, 1902. The points of a cut-out are held apart by a pin which rests upon a fusible material, the latter being melted when the carbon has burned away.

748,149. REGULATING DEVICE FOR ELECTRIC CIRCUITS; Malcolm H. Baker, New York, N. Y. App. filed Dec. 8, 1902. The circuit is controlled electrically by means of two coils, one of which is movable with relation to the other, both windings standing in inductive relation to a suitable core and one being connected with a special core forming a magnetic continuation of the first named core.

748,182. MAGNETIC POWER MECHANISM; Frederick Hachmann, St. Paul, Minn. App. filed May 8, 1903. Motion is obtained in a power apparatus by utilizing the difference in the forces required to move an armature laterally out of a field of force and axially or in a parallel direction therefrom.

748,185. ELECTRIC ARC LAMP FOR MULTIPLE OR PARALLEL CIRCUITS; Robert H. Henderson, Newark, N. J. App. filed March 30, 1903. A reactance device in series with the electrodes, having a floating core operating against a counterweight to keep the electrodes together when the lamp is not burning and to bring them together when the terminal arc voltage becomes too high in the normal operation of the lamp.

748,240. BEARING THERMOSTAT; George A. Wall, Providence, R. I. App. filed Oct. 28, 1902. The casing is attached to a shaft bearing and contains a circuit closer held open under tension by fusible material.

748,268. MAGNETIC CONTACT BOX FOR ELECTRIC TRAMWAYS; Alfredo Diatto, Turin, Italy. App. filed April 8, 1902. When the contact in the box is moved, a magnetic field is established and Foucault currents opposing the movements of the field are at the same time created with an object of preventing the formation of an arc between the various parts of the apparatus.

748,306. RECEIVER; Frank E. Peters, Fort Washington, Md. App. filed May 2, 1903. The particles of a coherer are constantly rotated between the poles of a magnet which at the same time serve as the terminals of the aerial circuit.

748,309. ELECTRIC HEATING PAD; William Richards, Los Angeles, Cal. App. filed July 2, 1902. A resistance wire interwoven with the threads of a blanket and connected with plugs for attachment to a circuit.

748,322. TROLLEY DEVICE; Ralph P. Tisch and Robert Kissinger, Hebron, Ohio. App. filed May 23, 1903. The wheel turns on cone bearings having threaded shanks by which they can be set up to compensate for the wear.

748,323. THERMOSTAT; Geo. A. Wall, Providence, R. I. App. filed Oct. 28, 1902. Details.

748,337. SOCKET FOR INCANDESCENT ELECTRIC LAMPS; Charles Blakeley, Covington, Ky. App. filed June 18, 1903. Details.

748,338. SOCKET FOR INCANDESCENT ELECTRIC LAMPS; Charles Blakeley, Covington, Ky. App. filed June 18, 1903. Details.

748,354. AUTOMATIC CONTROLLER FOR ELECTRIC PUMPS OR THE LIKE; Charles H. Durning, Swissvale, Pa. App. filed Jan. 26, 1903. The motor switch is controlled by a differentially wound magnet.

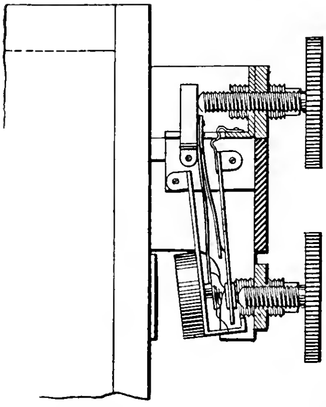
748,360. IGNITING DEVICE; William Gardner, Brooklyn, N. Y. App. filed Sept. 27, 1902. A box containing a battery, an induction coil and a metallic torch conveniently put up for cigar lighting purposes.

748,397. CIRCUIT CHANGING APPARATUS; William Meyer, Chicago, Ill. App. filed Oct. 10, 1901. Improvements in a telephone key-switch.

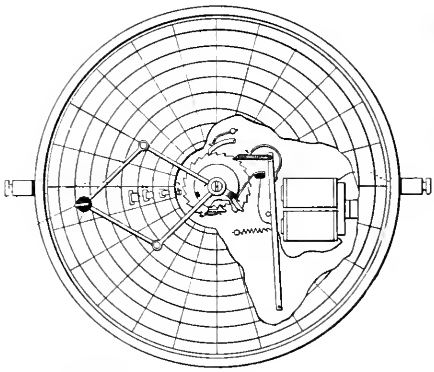
748,408. ELEVATOR SIGNALING APPARATUS; John McLean, New York, N. Y. App. filed Nov. 16, 1901. The indicators in the car are restored automatically as the car passes the landing to which they correspond.

748,409. ELEVATOR SIGNALING APPARATUS; John McLean, New York, N. Y. App. filed Dec. 8, 1902. The elevator attendant can send a return signal to the floor from which a call signal is sent, to indicate to an intending passenger which car will first arrive at the floor traveling in the direction in which the passenger intends to travel.

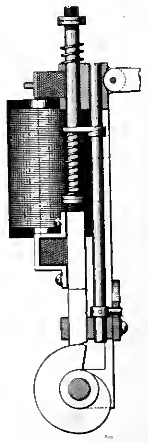
748,422. TROLLEY; Walter J. Rowley, Allegheny, Pa. App. filed May 7, 1903. Opening and closing levers to entrap the wire within the groove of the wheel.



748,442.—Vibrator for Induction Coils.



748,502.—Electric Signaling Apparatus.



748,534.—Electric Generator for Intermittent Currents.

748,441. TROLLEY; Thomas F. Varley, Lowellville, Ohio. App. filed Aug. 14, 1903. Pivoted guards to retain the wire are counterweighted to yield when they strike an obstruction.

748,442. VIBRATOR FOR INDUCTION COILS; Richard Varley, Providence, R. I. App. filed Nov. 6, 1903. In this vibrator the armature is put under motion by the attraction of the coil and then strikes a hammer blow against a circuit controlling lever to give a quick break of the circuit; on the return stroke of the armature, the circuit closing lever is pressed into intimate contact with the end of the contact screw.

748,445. INCANDESCENT LAMP SOCKET; Charles Wagner, Brooklyn, N. Y. App. filed May 2, 1902. A porcelain block having a lamp socket in one end and a axial metallic plug into which side openings lead for the attachment of wires to avoid external metallic parts.

748,450. BLOCK SIGNAL SYSTEM; Elmer E. Wolf and James B. Williams, Springfield, Ohio. App. filed June 20, 1902. Details.

748,451. RAILWAY CROSSING SIGNAL; Elmer E. Wolf and James B. Williams, Springfield, Ohio. App. filed June 20, 1902. In case a train reverses its direction just before it passes the crossing, the signal is rendered inoperative automatically.

748,488. CONTROLLING SYSTEM FOR CONVEYERS; Arthur C. Eastwood, Cleveland, Ohio. App. filed Oct. 16, 1903. Automatic devices for controlling the movements of cars that convey material to the top of blast furnaces.

748,501. ELECTRIC SIGNALING APPARATUS; Felix B. Herzog and Schuyler S. Wheeler, New York, N. Y. App. filed Jan. 25, 1886. The index of a transmitter is constructed to move either radially or in a circle over the face of a circular dial and the receiving index partakes of the same movements.

748,502. ELECTRIC SIGNALING APPARATUS; Felix B. Herzog and Schuyler S. Wheeler, New York, N. Y. App. filed Jan. 25, 1886. A modification of the preceding invention.

748,534. ELECTRIC GENERATOR FOR INTERMITTENT CURRENTS; Malcolm P. Ryder, White Plains, N. Y. App. filed March 11, 1903. An armature is lifted into a field by the slow movement of a cam and is suddenly released to impart a quick motion which generates sufficient current to supply a spark.

748,557. ELECTRICALLY CONTROLLED RAILWAY SWITCH; Frederick T. Kitt, Denver, Colo. App. filed March 4, 1903. Details.

Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

CONTENTS.

THE MODERN PRINTING OFFICE.

We imagine that a great many of our readers will have followed with interest the description that has run through three issues of this journal and now closes, on the electrical equipment of the Government Printing Office at Washington, D. C. The plant is not only striking on account of its size, but because of the extraordinary degree to which electric motors are utilized in driving the apparatus, no fewer than 600 power motors, many of large size, being in operation under that one roof. Another remarkable feature is the degree to which electric heating is used, many of its applications being highly original and directly illustrative of the economy and efficiency of electric heating under various special conditions. A third notable feature is the exclusive use of incandescent lighting. The spaces are so large we could well imagine excellent opportunities for the employment of arc lamps, but incandescents have apparently been found equal to every emergency.

THE DOWN-TRODDEN EMPLOYER.

The attention of the legal gentlemen who wrestle with tort cases is respectfully drawn to the extraordinary case just decided in England, in which the employer was held responsible for the death of a workman from lightning. We have long remembered with joy the suit for two dollars brought against a western railroad, said sum being the value of one rooster scared to death by a train, but the present litigation establishes a new record. The victim of this new outrage on the part of capital was working on a scaffold some twenty feet from the ground when a thunder shower came up, and the lightning leaped upon him and slew him, incidentally bagging a man on the ground floor of the same building. After hearing expert testimony and much argument from counsel, the learned judge decided that the accident arose out of the victim's employment in an elevated position, and gave judgment for the plaintiff in the sum of £300 and costs. Under these painful circumstances, what balm in Gilead is left for the well-intentioned contractor? Must he furnish a sort of portable cyclone cellar, into which the working force can be bolted by the foreman at the approach of Jove's batteries, or will it be sufficient to protect the neighborhood by temporary lightning rods? Would the liability insurance companies include this new risk gratis in their policies, and if not, what would they charge for the added protection? We have seen some queer cases decided in this country, but for sheer audacity this one must be placed upon a pinnacle of glory quite its own, and well guarded by lightning rods. Even the annals of claims against street railways could not furnish anything so spectacular. Employers in this country sometimes grumble at their hard lot, and feel that the workman holds the big end of the whip; but they should join in a pæan of thanksgiving that they live in a free and enlightened country, where they have nothing worse than walking delegates to contend with, and where horse sense is a common virtue of the judiciary.

THE WEATHER OF 1912.

The war of 1812 and the weather of 1912 have not a very close relationship, on the surface, to the copious showers of last summer and the mild days of November, but knowing enough we should find it all of a piece. Tennyson once remarked rhythmically that if he could comprehend the meaning of a flower snatched from the crannied wall, then had he mastered the philosophy of the universe. Thus, too, could we interpret the magnetic disturbances and auroral storms of recent date, there might readily be predicted, with accuracy, revolt and distress in Russia, war in Manchuria, good crops in Kansas, failure of hops in England, easy money in Wall Street, and a renewal of dividends on Steel common.

Abbe Moreux, director of the Bourges Observatory in France, is authority for the statement that we shall probably have rainy weather up to 1912, basing his forecast on the recent magnetic derangements that paralyzed the telegraph, caused the telephone to be tongue-tied, and even held up the trolley cars along Lake Leman. Such damp vaticinations must lighten the labors of other meteorologists, and determine the course of events. Maximum sun spots to whose outbreaks the terrestrial globe responds perforce, in these magnetic storms, are scheduled every 33 or 35 years, and as the next maximum is due in 1904-5, earthquakes, mine explosions, wet weather and consequent social and political results, of cosmic sweep, unfailingly impend, in the near future. Off-hand, this extra evaporation of the ocean is a good thing for the United States, whose inland central regions everlastingly cry aloud for more moisture; but the outlook in the British Isles, which had over a yard deep of rain last year, is less cheerful. Something more than a Chamberlain programme is needed to mitigate the conditions there. Moreux may be wrong, but the unvarying precision of Weather Bureau meteorological diagnoses argues strongly in his favor, and points to a large output of rubber coats and umbrellas during the next decade.

The Theory of Wireless Telegraphy.

In our last number we gave an abstract of a paper recently read by Prof. Blondel on the theory of wireless telegraphy for the advancement of science before the French Association. The theory which Prof. Blondel enunciates, in a most interesting manner, is entirely in accordance with that which we have consistently upheld in these columns, as will be found by reference to the issues for August, 1902, and other dates. That is to say, wireless telegraph waves are essentially semi-Hertzian waves attached to the conducting surface of the earth or sea. All that is known concerning the action and development of free Hertzian waves is immediately applicable to wireless waves, after allowing for the curvature of the conducting earth. In general, therefore, after passing to some distance from the sending antenna, the waves become virtually hemispherical, until their radius of emission reaches a length of fifty miles or so. After this radius has been reached, the hemisphere must reach the conducting strata of rarefied atmosphere, or strata of atmosphere having a degree of rarefaction that produces in vacuum tubes an electrical conductivity equal to, or even greater than, that of sea water. This would have the effect of checking further vertical expansion. Beyond this distance the wave would expand in two dimensions instead of three; or in a layer of non-conducting air, say fifty miles in thickness, with absorption in the conducting liquid ocean beneath, and also in the attenuated gaseous ocean above.

If the sea or land had perfect conductivity the waves would advance without absorption or penetration, the electric currents at the feet of the waves being confined to a mere infinitesimal skin upon the surface; just as very high-frequency alternating currents are confined to a thin skin of the copper conductors over which they travel. With imperfect conductivity, however, the waves sink more or less deeply below the surface of land or sea, as they advance, suffering absorption thereby, and producing real accompanying currents of the alternating type in the upper layers of land or water. There would be one alternation of current in the ground for each half wave through the air above. In the salt water of the ocean the current should penetrate less deeply than in the ordinary surface soil of the land. Fessenden has stated that this is a fact observed experimentally. Over deeply frozen ground of very feeble electric conductivity, there should be much reduced range of effective wireless telegraph transmission, unless good ground connection can be established at both the sending and receiving antennæ. The paper of Prof. Blondel gives the most complete and satisfactory mathematical development of the theory of wireless telegraphy that has yet come to our notice.

The Engineer and Academic Distinctions.

The engineering profession is by no means a bed of roses under the most favorable circumstances, but there seems in this country a singular lack of generosity toward the engineer on the part of those who would naturally be expected to appreciate his work. Members of the profession often grumble about the material recognition of their efforts, but this they do in common with most other professional men. In this land of freedom where every man holds himself to be a little better than his neighbor, it is perhaps natural that tangible assets should be the final criterion of true greatness, but there is still a more thoughtful side to American life and those there are who could and should recognize professional triumphs in all of the learned professions alike. We have been glancing over recently a list of the academic distinctions conferred this year by distinguished institutions of learning, and it is curious to note how completely the engineering professions were left out of the reckoning. Empty honors, one may perhaps say, but the recognition of scholars is certainly no less valuable than the appreciation of the ignorant, and in the long run other honors sometimes prove to be empty. And here academic honors are almost the only ones available for the acknowledgement of professional fame. Under the rule of effete monarchies where the Order of the Blue Buzzard and the Grand Cordon of the Green Turtle are considered distinctions to be coveted, and worthy emblems of national fame, their spectacular value, we admit, deserves acclamation. Besides, at a public function under the said effete monarchies, one finds some parti-colored breast plate necessary to avert the danger of being taken for a waiter. Here, where the advocate of true democracy should not mind being taken for a waiter, less flambuoyant honors serve the purpose.

But while the orders to which we have referred are often conferred abroad upon distinguished professional men, among them no small number of engineers, our American Universities are as chary of giving out honors to engineers as if each one carried a pension for life. One of the elements that makes against the growth of American science, pure and applied, is this very lack of everything like public distinction. One would think that the universities would be quick to appreciate the distinction of their sons in the engineering professions. Alas, the alma mater generally turns the other way or administers a glary stare and the cut direct. A returned missionary to Nova Zembla, a briefless attorney who by close study of ward politics has achieved notoriety, or a patron from whom a bequest may ere long be hoped—these receive the glad-hand degree. Of course, it may be held by finical apologists that one of the difficulties in the way of honoring the distinguished follower of applied science is the lack of a suitable degree to fit the case. For instance, we know few engineers of large experience who have not oftener given than received the degree of D.D., fewer still to whom an S.T.D. would be aught but a burden hard to live up to. A.M. has had no standing for many years by reason of its being given by some institutions to any graduate who has for three years kept out of jail and retained $5 to pay for the diploma. Ph.D. and D.Sc. are now held mainly as working degrees and seldom given *causa honoris*, although specially appropriate for scientific distinction. LL.D. and D.C.L. are used as honorary degrees and for purposes quite outside their original meaning. They are certainly as appropriate for distinguished engineers as for physicians, authors and politicians, and should not be begrudged when deserved. The pilots of industry certainly deserve far more recognition than has yet been accorded them in this country. Abroad they rank with the captain; here they are little more honored than the cook. But although a conference of the five most noted engineers in the country on a problem of international importance would not receive from the daily press a notice given to a fashionable divorce suit, the profession certainly deserves from its academic brethren more of fellowship and appreciation than it at present receives. Perhaps a few years may see a change for the better, for the time has come when, if ever, the forces of education and progress must work shoulder to shoulder for the common weal.

ELECTROSTRICTION.

Prof. More's article on electrostrition, which appears on page 127, opens up a very interesting question. According to the existing theory of electromagnetism due to the labors of Faraday, Maxwell and a host of others, any medium which is electrified stores electric energy to the extent of $K R^2/8\pi$ ergs per cubic centimeter, where K is the dielectric constant, and R the electric intensity, in abstatvolts per centimeter. Accompanying this storage of electric energy in space is a tension, or pull, along the direction of the electric flux, and a pressure, or shove in all directions at right angles to the flux. Similar conditions apply to magnetized space. The behavior of electrified bodies is apparently in complete conformity with the above propositions. In fact, the dictum that unlike charges attract, and like charges repel, may be regarded as a condensed statement of the proposition that a pull exists along electric flux paths, while a shove exists perpendicularly thereto.

The observable strength of the pull on an electrified pithball in an electric field, and the strength of the pull on a soft iron armature by an electromagnet, are consistent with the electric and magnetic tension and pressure equations. Moreover, when an electromagnetic wave is propagated in free space, the pressures and tensions in the plane of the wave form balance and disappear, according to theory, the shove of the magnetic flux just balancing the pull of the electric force, and vice versa. But in the direction normal to the wave front—that is, in the direction of advance of the wave—the electric shove and the magnetic shove coincide and aid each other instead of opposing and cancelling each other. Consequently, as was pointed out by Maxwell, the pressure, in dynes per square centimeter, in the direction of the wave's advance is numerically equal to the total voluminal electromagnetic energy of the wave front in ergs per cubic centimeter. This condition has been experimentally verified for arc light. A beam of light pushes where it strikes. Moreover, the power of a wave is equal to the product of this head pressure into the wave velocity, or the velocity of light.

But because in electrified ether there is a pull along the flux, and a shove perpendicularly thereto, it does not follow that the ether is deformed by these stresses. It may or may not be. There does not seem to be any evidence of distortion in electrified ether, nor any known means of making such distortion apparent, if it exists. Similarly, because in a dielectric substance, giving passage to electric flux, there are stresses in ether, it does not follow that there must be distortion in the solid, or mechanical strains. There might or might not be. If strains could be detected in an insulating solid such as glass, due to electric flux, these strains, if of a nature to correspond with the theoretical stresses of electric flux, would certainly corroborate the theory, but the absence of such strains would not necessarily refute the theory; because so little is known of the interconnecting mechanism between the ether and matter.

The strain in dielectrics due to the passage of electric flux through them is termed "electrostriction." Electrostriction has been claimed to have been observed by various physicists. Prof. More, however, in his article, takes the position that the effects which have been observed are spurious, and are due to other causes, such as the stresses between electric charges resident on opposite faces of a glass sheet, to which tin-foil coatings have been applied. He states that when care is taken to eliminate such independent and extraneous sources of stress, no electrostriction is detected by him, although his apparatus possesses abundant sensibility. It would be very interesting to have this experimental result confirmed by other observers. But whether the effect does or does not exist, is of no vital importance to the outstanding theory of electromagnetism.

THE METRIC SYSTEM IN 1903.

The tendency of the times to introduce labor-saving machines and by the exercise of intelligence, to save each other's labor is borne out in the sure progress that the International Metric System has made during the past year. This country made a great step in advance when it adopted a decimal currency in 1785. Prior to that time there existed time-honored but cumbersome pound, shilling and penny currency. There can be no doubt that a shilling, as a duodecimal thing, is theoretically superior to a dime, for it admits of division into sixpences, fourpences, threepences, twopences, pennies and halfpence; whereas the dime is only evenly divisible into five-cent pieces, two-cent parts and cents. Nevertheless, we do not know of anyone who considers that the old duodecimal system was superior to our dollar-and-cent system. Our dollar system is much simpler to learn, to think in, to compute and to reduce.

It was stated last year in evidence before the Congressional Committee on coinage, weights and measures by a specialist in national education, that one-twelfth of the average eight years of elementary school education in America, or about two-thirds of a year of study, could be saved if the metric system took the place of our multitudinous medley of customary weights and measures, and that the waste of money in teaching the present system to children, apart from the question of the value of the waste time to the children, was eighteen millions of dollars annually. This estimate seems a reasonable one. Manifestly, if the children could be put on the same level as the children of France, Germany and the other European countries in this respect, the assumed two-thirds of a year saved could be devoted to other things that cannot now be included in the elementary school curriculum. Our crude and unscientific system handicaps all our citizens, in education, in thinking, in application, and in computing. The very best system in the world should only be good enough for the American people to adopt.

Great Britain has made greater visible progress than the States toward the metric system during the past year, mainly owing to the official actions of her colonies. Most of these have either singly or jointly petitioned the British Government to adopt the metric system throughout the Empire. We learn that Lord Belhaven has given notice of introducing into the House of Lords early next session a bill for the compulsory adoption of the metric weights and measures throughout the United Kingdom, and that Lord Kelvin will second the motion. We wish the bill every success, and feel sure that any branch of the English-speaking people adopting the metric system will give the signal for all branches to follow forthwith.

Motor Automatic Switch Litigation.

The United States Circuit Court of Appeals, sitting at Chicago, Ill., rendered on January 5 a decision confirming a decision of Judge Kohlsaat of the Lower District Court, rendered March 26, 1903, sustaining the Blades automatic motor switch patent of January 7, 1900. The claim of this patent in suit was the combination in a shunt-wound motor of a magnet in the field circuit with a hand switch adapted to open and close the armature circuit, said switch being arranged to be held in its closed position by the said magnet in the field; and means for automatically retracting the switch to its initial position when the magnet is de-energized by the cessation of the current through the field circuit.

The court, in its opinion, held that there was patentable novelty in the application of an under-load retaining magnet to a manual starting box, in the location of such a magnet in the field circuit of a self-regulating shunt-wound motor, and in adjusting it to act in that location with the starting box located in the armature circuit; and the court could find nothing in the prior art to militate against the allowance of the claim in suit. One inventor, preceding Blades, addressed his attention to the dangers of the self-regulating shunt motor in the constant-potential circuit that comes from the cessation or material loss of current, but he missed the mark by directing his efforts to the wrong point—the main switch. As the court reads the Shepardson patent referred to, it contains no hint of the Blades structure. The parties to the suit were the Cutler-Hammer Manufacturing Company, appellees and owners of the Blades patent, and Edward W. Hammer and Edwin R. Harding, appellants.

The Institute Annual Dinner.

Preparations are being actively pushed for the annual dinner of the American Institute of Electrical Engineers on February 11, as already noted in these pages. The dinner will be held in the grand ball room of the Waldorf-Astoria, and it is expected to be a very large and interesting affair. It is intended to make the feature this year the celebration of the twenty-fifth anniversary of the successful introduction of incandescent lighting, and to this end the Edison Medal Association recently formed has joined hands with the Institute and intends to present to the Institute at that time the fund raised by it to found an Edison Medal, the first in the Institute's history. Tickets for the dinner will be $7 for members and $5 for ladies, without wine. It is also proposed to dispose of some seats in the boxes for those who might like to witness the proceedings and hear the speeches after the banquet; the price of these tickets to be a dollar each. Mr. Arthur Williams, of the New York Edison Company, and a member of the dinner committee, of which Mr. Calvin W. Rice is the chairman, has been put in charge of the decorations, which will be of an elaborate and sumptuous nature worthy the occasion. A very handsome menu is also being prepared which every guest will gladly preserve as a permanent souvenir. Mr. Rice has appointed Messrs. F. C. Bates and Calvert Townley as a committee on tickets, etc., and Messrs. C. W. Price, E. H. Mullin, Bancroft Gherardi, Jr., and W. J. Hammer as a committee on invitations, etc. The programme of speakers will be announced shortly.

The Edison Medal Association has also issued this week its formal circular, the details of which were given by us last week, as to the foundation of the Edison Medal to be awarded by the Institute each year to the student in electrical engineering whose thesis or recorded research shall be deemed most worthy of honor. This association, through its executive committee of thirty-one and its general committee of one hundred, is already actively at work and reports most gratifying results as to the collection of subscriptions to the fund, the contributors to which are Mr. Edison's associates and friends during the past twenty-five or thirty years of his work. It is remarkable how wide a range of development is included by this phrase, and how many men in different fields of occupation find their sympathies and approval enlisted by the purpose of the association. We are requested to state by the association that in case any who should contribute to the fund and desire to do so, have not received circulars and subscription blanks, they will communicate at once with Mr. R. T. E. Lozier, secretary, 220 Broadway, or Mr. Frank S. Hastings, treasurer, 80 Broadway. The chairman of the association is Mr. Samuel Insull, of Chicago, and Mr. Edison's pioneer associate, Mr. Charles Batchelor, is vice-chairman. It may be mentioned again that the date of the dinner, February 11, is Mr. Edison's birthday. He was born in 1847, and was, therefore, but thirty-two when the incandescent lighting art, in whose commercial development and perfection he was so strikingly prominent, may be said to have begun in 1879.

Destruction of A. I. E. E. Property by Fire.

The total destruction by fire on December 28th, 1903, of the printing house of McIlroy & Emmet, 108 Liberty Street, New York, means considerable loss of time and material to the American Institute of Electrical Engineers. The amount of the loss from a financial viewpoint cannot be even approximately estimated at this time, for the reason that the severe cold wave has caused the debris of the fire to be coated with ice, so that it is impossible now to extricate what may eventually be recovered. There is also a question as to what portion, if any, of the financial loss will fall on the Institute.

Secretary Pope estimates that on the evening of December 28 the following unfinished work was contained in the printing shop:

	Pages.
ELECTROTYPE PLATES:	
Vol. XX, Transactions, Sept. to Dec., 1902	306
Vol. XXI, Transactions, Jan. to June, 1903	601
Vol. XXII, Transactions, July to Dec., 1903	336
Total electrotype plates	1,243

	Pages.
TYPE: PAGE FORM:	
Vol. XXII, Transactions	414
Advance copies December papers	47
Pocket-Catalogue of Membership, Edition of August 1, 1903	87
Total	548

	Galleys.
GALLEYS:	
Mailing List	29
New Catalogue of Membership	36
Total	65

It is possible that some of these plates and galleys may be saved. The amount of salvage, however, cannot be determined until the insurance adjusters have finished their work; unfortunately, the adjusting is seriously hampered by the inclement weather.

The Institute office has on file authors' corrected copies of all the papers and discussions, also partially revised copy of the mailing list and catalogue of membership, so that nothing has been lost which cannot eventually be reproduced. The reproducing of the papers and discussions will, however, take considerable time.

Northwestern Electrical Association.

The annual meeting of the Northwestern Electrical Association at the Hotel Pfister, Milwaukee, Wis., on January 20, 21 and 22 promises to be as usual an interesting and successful affair. Mr. Thomas Mercein sends us the following programme:

Wednesday Morning Session—Convene 11.30.—Roll-call, reading of Minutes, president's address, secretary and treasurer's report. Afternoon Session.—Appointment of Nominating and Membership Committees, applications for membership, reports of all committees except Nominating, miscellaneous business. The following papers will be read: "Storage Batteries for Central Station Work," J. H. S. Waring; "Peculiarities of Magnets," Richard Varley; "Rectifiers," W. Scheidel. Evening.—Theatre party. Thursday, Morning Session.—The following papers will be read: "Double-Current Generators in their Connection with Double-Current Supply," W. L. Waters; "Central Station Heating," W. E. Schott; "Standard Practice in the Use of Alternating-Current Electrical Apparatus," J. J. Gibson. Afternoon Session.—Report of Nominating Committee and election of officers. The following papers will be read: "Steam Turbines" (illustrated), James Lyman; "Rectifiers," Prof. G. F. Burgess; illustrated lecture on Radium, Prof. R. A. Milliken. Evening.—Annual banquet. Friday Morning.—Unfinished business. Adjournment.

The Government Printing Office—The Electrical Equipment of the Largest Printing Office in the World—III.

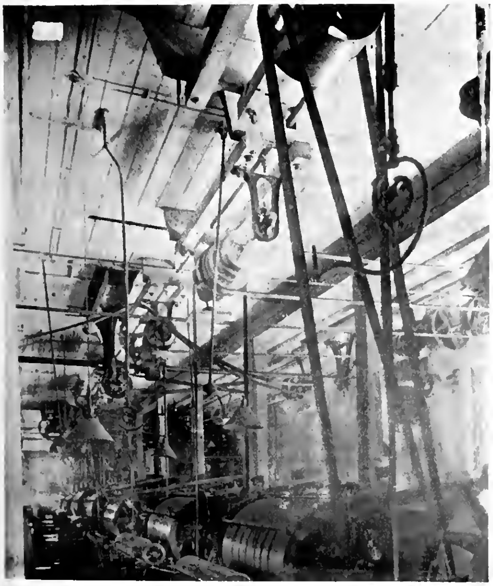
(Concluded.)

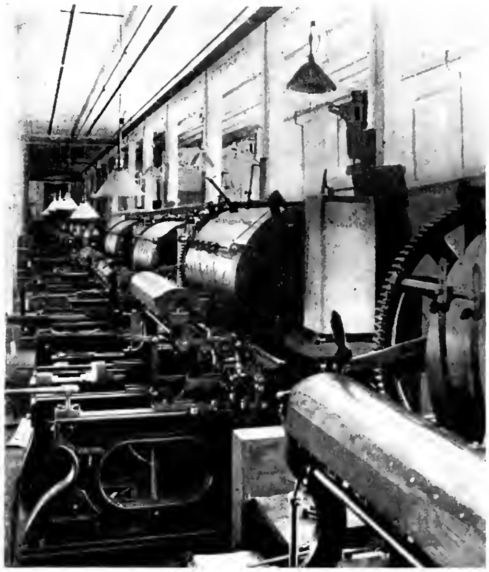
PRESS DRIVING.

THE two preceding sections of this article have dealt with the general details of the Government Printing Office at Washington, the power plant, the wiring distribution, the elevators, the electric heating equipment, and part of the electrotyping work. While none of these features has been gone into exhaustively, the text and illustrations required have filled some sixteen pages of this journal, and as this present section shows several more pages are required to note even briefly the leading points in regard to the motor equipment for press driving, and other parts of this most interesting and impressive installation. In fact, as remarked by Mr. Tapley, the chief electrician, who for two or three years past has been giving ceaseless attention to the problems connected with the plant, it would require a good week to give but a few minutes to each of the constituent items which make the largest printing office in the world such a remarkable example also of the successful application of electricity to the printing and graphic arts.

Before passing on to the description of the equipment, it may be noted that from the very necessities of the case Mr. Tapley has had to give more attention to press driving than any other question, and that his classic paper on the subject of the application of electric motors to running press machinery, presented before the electrical section of the Franklin Institute in 1899 still remains one of the best treatises available in regard to the economies and other advantages of the electric drive. Now five years later, its wealth of detail and experience renders it of continuing value, and it might well be quoted here in extenso if space permitted. Many of the arguments and ideas then advanced have, however, in the meantime, become embodied in current practice and find exemplars in the enlarged and new plant under review. One or two of our pictures are of the "before and after" class, Figs. 31 and 32, and in that connection as summing up the situation we may venture to quote from Mr. Tapley as follows: "The advantage to be gained from changing over from belted, steam driving to individual electric motor for printing press work is not alone in power saved, but better grade of work, less spoiled sheets, cleaner, healthier rooms for employees, less repairs to machinery, and most of all an increased product without a corresponding decrease in value of presses by running at too high speed." This, indeed, we might supplement by quoting with renewed emphasis his remark then also made: "There has never been a hitch in the motive power; not a motor has given out. In fact, such a freedom from interruption of power has never been known in the history of the Office as during the past three years, or since we adopted electric power." It will be remembered that in the opening portion of this article we dwelt upon the vital importance to the Government of uninterrupted operation, and cited a number of instances as to the publications, daily and of other periodicity, that must issue punctually from this wonderful bureau of intelligence and information.

The Government Printing Office was one of the first establishments to take up the direct application of motors to printing machinery, and a more thorough study of the subject has probably been made at this plant than at any other plant of the same character in the world. Before the purchase of the first motors a complete investigation was instituted by the Hon. Theodore Benedict, then Public Printer, and he detailed Mr. W. H. Tapley to carry on this work, Mr. Benedict, however, taking great personal interest in the securing of the requisite information. There only being a few establishments where motors had been applied direct to printing machinery, a comparatively small amount of data could be gathered by Mr. Tapley in his search, and therefore many of the methods of application were original. The first specifications issued by the Government Printing Office covered the furnishing of a lot of about sixty motors and four generators and a switchboard. The motors were wound for a pressure of 120 volts, this voltage being decided upon from the fact that a large part of the load was lighting, and it was not desired to have separate generators for operating the motors.





FIGS. 31 AND 32.—PRESSES WITHOUT AND WITH MOTOR EQUIPMENT.

In the original installation the motors in practically all cases were geared to the respective machines, this method of application being at that time considered the most advantageous. In the case of a number of ruling machines, some special speed reducers were employed and the motors of one-sixth horse-power capacity were coupled direct to the reducers. There were about thirty of these combinations installed at that time. In controlling the speeed of the motors applied to the various presses and other machines where variation in speed was desired, resistance in series with the armature was employed, in most cases the resistance being separate from the controller. The controller was placed in a position convenient to the operator. In a few instances it was found advisable to install a motor driving a group of machines such as in the electrotype foundry. At that time it was not deemed wise to attempt to apply motors to individual machines where they differed in character to such an extent, and especially as to the question of speed.

As a result of the benefits shown by the introduction of electric power, particularly from the point of increased output, motors were added from time to time until practically all shafting in the old buildings was eliminated. In some of the later installations direct connected type motors were used in driving certain types of presses, such as the Huber. In these cases the motor was mounted on the press shaft, the machine being bolted directly to the frame of the press. In some of the later installations, field weakening besides resistance in series with the armature, was introduced and found satisfactory. The question of reliability being an important factor in the operation of the Government Printing Office, instead of depending on fuses to protect the motors in case of excessive overloads from various causes, Mr. Tapley decided upon the wise plan of protecting each motor with a circuit breaker. This, of course, added considerably to the expense of the motor outfits, but has been found in practice to be an excellent investment.

The electrical propositions presented in connection with the new

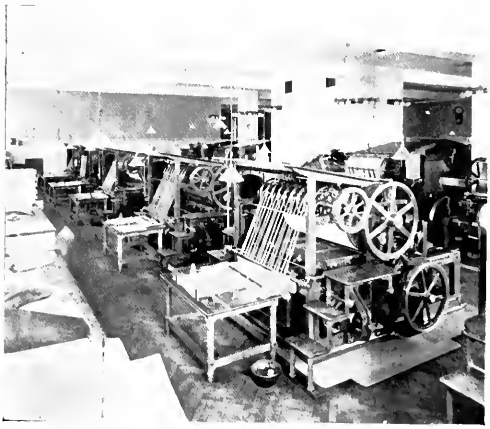


FIG. 33.—FIVE TWO-REVOLUTION PRESSES, MOTOR-DRIVEN.

Government Printing Office were most intricate, and all credit is due to Mr. Tapley in solving the various problems due chiefly to the tremendous proportion of current going into power apparatus. One of the most important was the continuance of the use of the existing voltage or the installation of 250 volt dynamos. After some weeks of careful examination into the various details connected with this problem, it was decided to adopt 125 volts for the new equipment station. The new Office is as stated above the most complete and unique plant of its character in this or foreign countries. The building alone contains over 600 motors in sizes from 1-6 to 100 horsepower and over 500 of the motors are of Crocker-Wheeler manufacture. In the new equipment many novel methods of application have been evolved, this being particularly so in the electrotype foundry, in which department every machine is individually driven as in the other departments. In the application of motors to presses, chain drivers have been largely employed, the motors (which are of the semi-enclosed type) being placed inside of the press. In the new building there is absolutely no shafting, which fact strikes one very forcibly when making an inspection of the plant. This will be touched upon again.

At the outset of this discussion of the power consumers, and the methods of driving the machinery it may be well to briefly collate a few of the more important features concerning the equipment for supplying power which were described in detail in part I of this article. The engine-generator plant comprises four units, each a direct-connected set, consisting of an Allis cross-compound Reynolds Corliss engine and a Crocker-Wheeler direct-current, 125-volt dynamo. In the order of their installation the sets are of the following sizes: one of 300 kw, one of 125 kw, and two of 600 kw each. At the generated pressure of 125 volts there is a total current capacity of 13,000 amperes, when the generators are run at their rated normal load, and with their ample ability to run at 25 per cent. over-load continuously for periods of four hours, it is possible, though beyond realms of the probable, to carry a load of 16,250 amperes for that length of time.

The power and lighting circuits, as has been described fully, are kept separate on the board and throughout the building, although the pressure is the same in both. This precludes the flickering of the electric lights with every fluctuation of the motor load, and possesses advantages in the way of safety and uninterrupted service for the illuminating, independently of the conditions existing in the power system. We may well look to the Government Printing Office for typical examples of the best methods for individually driving presses and other machines employed in the printing art.

The size alone is not the only feature in which the present plant differs from its predecessor. Many modifications have been introduced in the method of drive—a large number of belts have been eliminated, and while at an earlier time gearing was regarded as the only method for positive driving, and was in all cases employed where it was desirable to avoid slipping, to-day but few gears are seen, the greater per cent. of them being supplanted by chain connections. Perhaps the highest degree to which the perfecting has been carried is presented in the few cases where all forms of intermediate connection whether belt, gear or chain have been avoided by resorting to direct-connection with the motor spindle. There are cases, however, where such a scheme, commendable though it may be, is entirely out of the question. Oftentimes slipping is desirable, especially if it proves to be the means of saving the motor or machine from excessive shock in ordinary running, or even more serious injury in case of accident.

For such service there is nothing to replace the old-fashioned belt, nor, indeed, is there much to be said against it when the circumstances of the machine's construction, or situation allow for a reasonably long distance between pulley centers, for then the tension need not be excessive.

There are given herewith a few illustrations selected as fairly representative of the drives in use on the various classes of machinery. Each indicates somewhat the nature of the problem it involves, while the excellence of the solution speaks for itself. Features that will be recognized as common to almost all the equipments are the

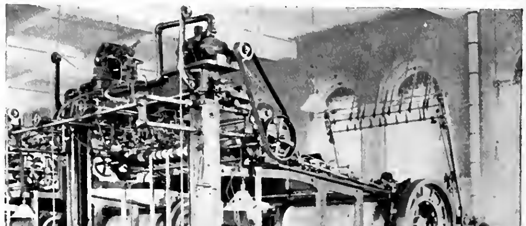

FIG. 34.—LARGE FLAT-BED TWO-REVOLUTION PRESS.

placing of the motor in a location where it occupies the least useful floor space, but remains accessible for examining or repairing. It will also be seen that the motor is incorporated in some way or other with the machine it drives, being invariably supported independently of the floor, walls or posts, and usually on a bracket elevated from the floor. Still another feature is the mounting of the controlling apparatus where it is handy, and at the same time protected from mechanical injury or from contact with dirt, chips, or in short, anything that would interrupt or interfere with its proper operation.

In Fig. 33 are illustrated five Potter 2-revolution presses, which are remarkable for their compactness and neat appearance. The same quality characterizes the driving element and the manner in which it has been embodied. It consists of a 5-horse-power Crocker-Wheeler motor located just under the bed, so that the sprocket, by which it drives through a Renold silent chain to the machine, is guarded by the steps and platform at the side of the press. The five presses shown, with a sixth, are all of this type in this room. Scarcely distinguishable, behind this row is an equal number of Hoe 2-revolution presses, each of which is driven by a 5-hp old-style bi-polar Crocker-Wheeler motor.

One of a line of machines of a larger size that deserves special mention is a flat-bed, 2-revolution Meihle press, shown in Fig. 34. This one is also chain-driven from a Crocker-Wheeler motor, in this case, of 7½-hp. The press has associated with it an automatic paper feeder, built by E. C. Fuller Company, of New York, which is geared-driven by a 1-hp bi-polar Crocker-Wheeler motor. Both of these motors are located in out-of-the-way positions, and practically add nothing to the space required by the machine proper.

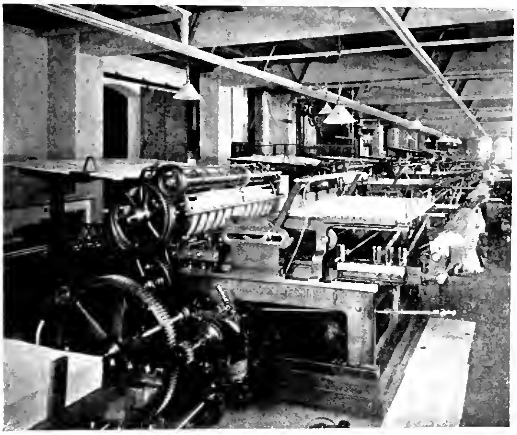

FIG. 35.—A LINE OF TWELVE MOTOR-DRIVEN PRESSES.

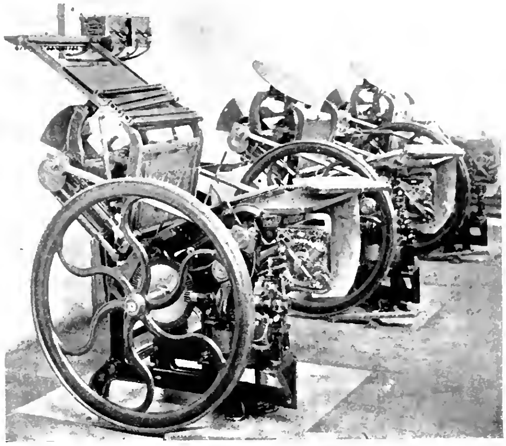

FIG. 36.—JOB PRESSES, SURVIVORS OF ORIGINAL PLANT.

In Fig. 35 a line of 12 presses are shown, the nearer ones being five of Whitlock make with 37 x 52-inch beds and direct-gear drive from 3-hp. Crocker-Wheeler bi-polar motors. Further on there are five Huber presses with 42 x 52-inch beds driven by 5-hp Crocker-Wheeler bi-polar motors, and two R. Hoe & Company presses driven by motors of the same size and style. These are a few of the pioneers which cling to the gear drive, a method which has its objection clearly indicated in the large-sized gear on the press. Now-a-days a slow-speed motor would be used to remove this objection, and it is not unlikely that this press, like the Meihle, would be chain-driven. A comparison between these two outfits is of interest as indicating the advance that has been made in this work even in five years' time.

Naturally there is considerable work executed in this plant on small job presses. Fig. 36 shows three typical outfits for such work. These are of Gordon make and are driven through bevel gearing by ½-hp Crocker-Wheeler bi-polar motors, mounted on the sides of the frames. These are also survivors of the original plant, but cannot yet be

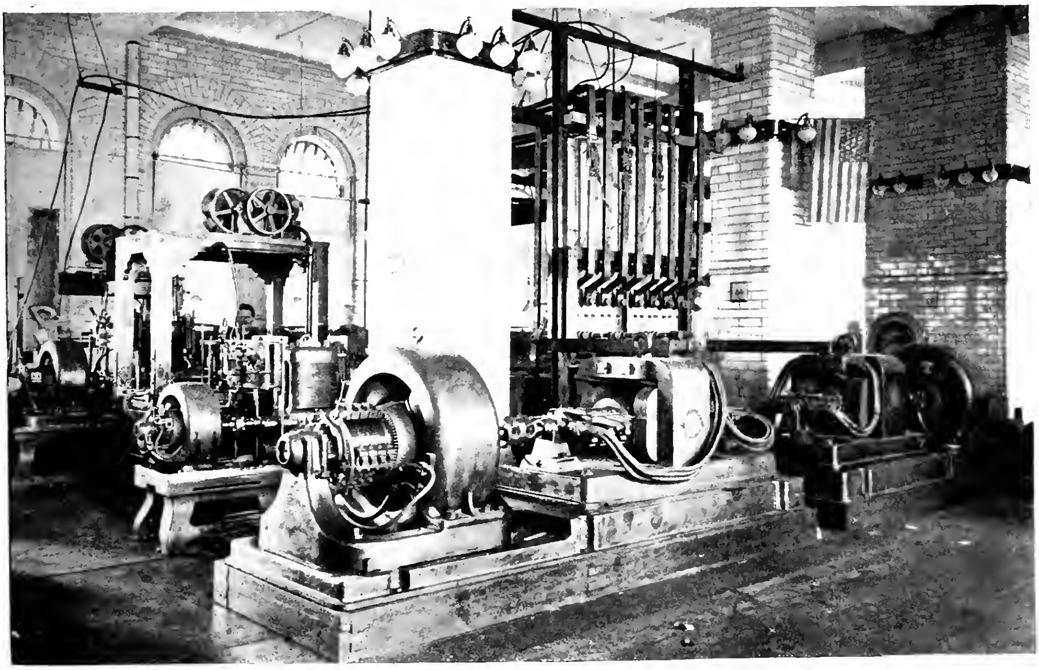

FIG. 38.—APPARATUS IN ELECTROTYPING DEPARTMENT.

classed as "back numbers." Much in their arrangement is quite worthy of more recent construction.

MISCELLANEOUS PRINTING OFFICE WORK.

So much for press drive. While it constitutes the more important side of the plant operations and constitutes the greatest per cent.

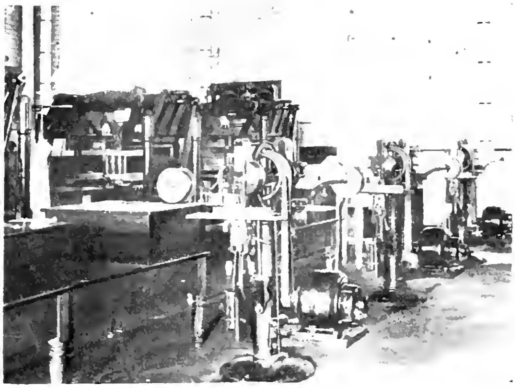

FIG. 37.—MOTOR-DRIVEN STITCHERS.

of the power load, it causes less perplexity in the matter of arranging satisfactorily than many of the smaller though indispensable machines, such for example, as the stitchers, shown in Fig. 37. These were built by R. H. Brown & Company, and are connected by the belt with ½-hp Crocker-Wheeler motors, mounted on brackets which are bolted to the supporting column of the machine near the base. The motor starter is mounted on the opposite side of the column, so that the outfit is entirely self-contained, and the floor about the base is easily kept free from litter.

One of the most interesting departments in the building, as noted last week, is that wherein are made the electrotypes for illustrations. As is well known, the process involves the use of current for depositing upon a wax impression of the original cut, a thin coating of copper which is then backed up with lead or white metal, and mounted on the block. All the apparatus necessary for this work is located in the section shown in Fig. 38, although all is not visible in the cut. Back of the columns are located the white glazed porcelain vats in which the wax impressions taken from the original half-tones, are immersed in a solution of copper sulphate, while current is passed through the solution, causing electrolytic deposition of free copper on the wax. Between the two piers may be seen the rear aspect of the substantial switchboard used in connection with the low voltage distribution to the electroplating baths. In the foreground are the two low-voltage generating sets which supply the current. These consist of Hanson & Van Winkle dynamos direct-connected to and mounted on the same base with 35-hp Crocker-Wheeler motors. On the left-hand side of the picture in the middle distance and the extreme rear are two so-called dipping machines. These are designed to do the same work; i. e., electrotyping, and to do it with greater rapidity, this being accomplished by causing the continual movement up and down of the plates while the deposition is taking place; hence the name "dipping machine." The principle of the action is that fresh, unexhausted copper solution is kept continually in contact with the surface, which causes the deposit to form faster. The device is an extremely useful one where rush work is undertaken, but is subject to the drawback that its work is of by no means as fine a grade as that obtained when using the slower process. The apparatus for causing the dipping is mounted on a platform over the tank and the motor-generator which serves that particular bath is located alongside. The nearer outfit is driven by a 7½-hp Crocker-Wheeler motor, and the other by a 10-hp.

After the formation of the electrotype plates it is necesary to trim them up before they are mounted on blocks. The machines for this work are shown in Fig. 39, the one on the left being a shaving machine for truing the back of the plate, or reducing it to a standard thickness; built by the Lovejoy Company, of New York. It is driven by a Crocker-Wheeler motor, mounted on a bracket secured to the legs at one end, right beside the controller and the terminal of the pipe conduit in which the wires are brought up through the floor to the motor and controller. The latter is placed under a protecting hood, as indicated, to exclude particles of metal and prevent the trouble due to short-circuits. The motor and controller are similarly mounted on the machine at the right, which is used for bevelling the edges of the plates, and was manufactured by the J. P. Felt Company, of New York. The controlling apparatus for each

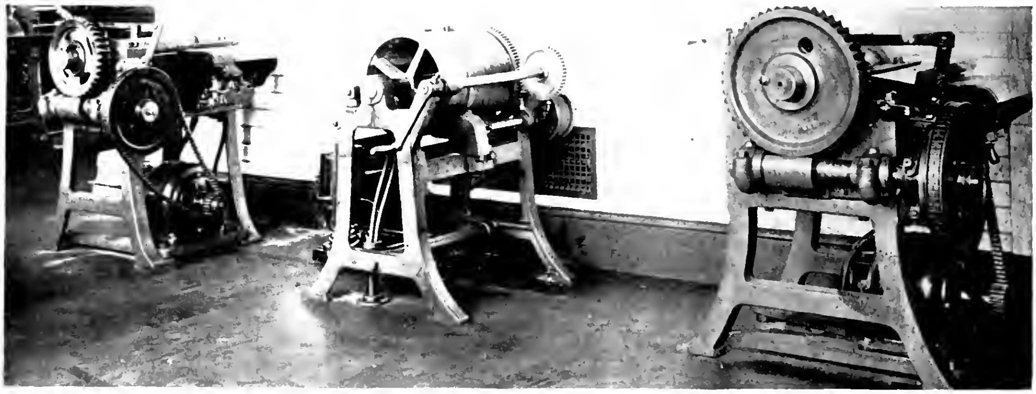

FIG. 41.—SHAVING AND BEVELING MACHINES ON CONGRESSIONAL RECORD AND SPEECHES.

FIG. 39.—ELECTROTYPE MOUNTING APPARATUS, MOTOR-DRIVEN.

machine consists of a starting box with a no-voltage release and a circuit-breaker for overloads, which also serves as a line switch.

Again the fact, so conspicuous in all the machinery, i. e., of supporting the motor in a contained manner somewhere upon the

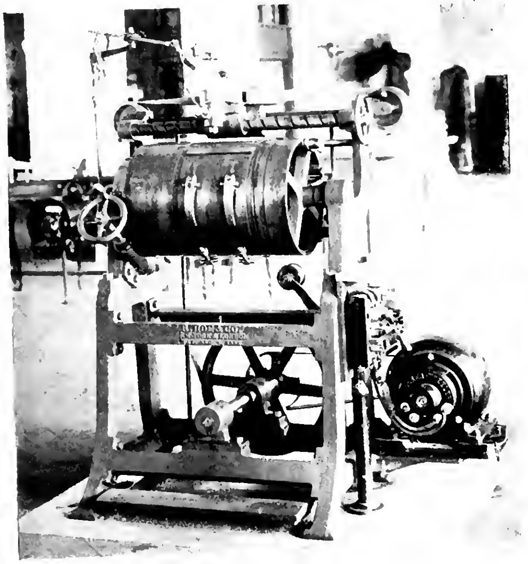

FIG. 40.—CARD-ROUTING MACHINE, MOTOR-DRIVEN.

machine is emphasized in Fig. 40, which illustrates a card routing machine built by R. Hoe & Company. This is for routing curved plates as used on cylindrical presses, the plates being fastened upon the surface of its drum. A 1-hp Crocker-Wheeler motor supplies the drive through a belt connection to a counter-shaft embodied in the lower part of the frame and in turn driving through a long belt which changes direction several times in order to impart motion to the spindle of the router on the adjustable tool head. In doing work on the machine the operator stands on the side shown in the cut, where with his left hand he may revolve the drum to extend the cut in one direction, while with his other hand he may travel the cutting head in a direction at right angles to the first. The same machine is shown at the right in Fig. 42, which brings out more clearly the course of the belt and the method of keeping it tight by means of an idler.

In Fig. 41, at the left, is shown a shaving machine, which is used on work for the "Congressional Record"; at the center, a bevelling machine and at the right a shaving machine, both of the latter being used in connection with the printing of speeches for the House and

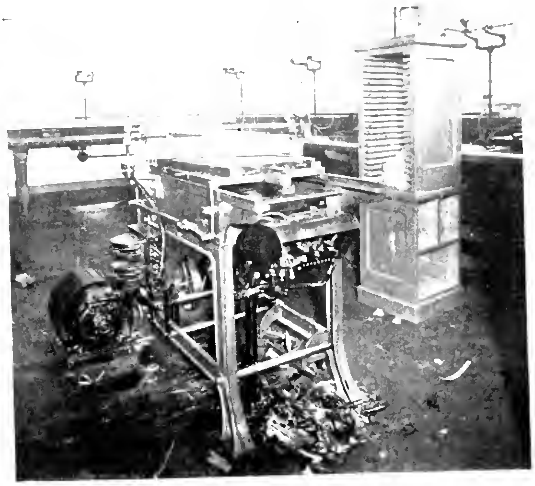

FIG. 43.—CASE SHAVER IN FOUNDRY.

Senate. The three were made by R. Hoe & Company, and are driven individually by 1-hp Crocker-Wheeler motor through Renold silent chains. A feature of these machines is the protection of the controlling apparatus, alluded to before, and clearly brought out in the picture.

Fig. 42 gives a general view of the electrotype finishing apparatus, showing routing, shaving and bevelling machines, saws, etc. Most of this apparatus is belt driven, in all cases by Crocker-Wheeler motors. Each one possesses merits of its own in the placing of the parts where they are out of the way and protected, yet at all times easily accessible. The advantage of avoiding overhead belts is

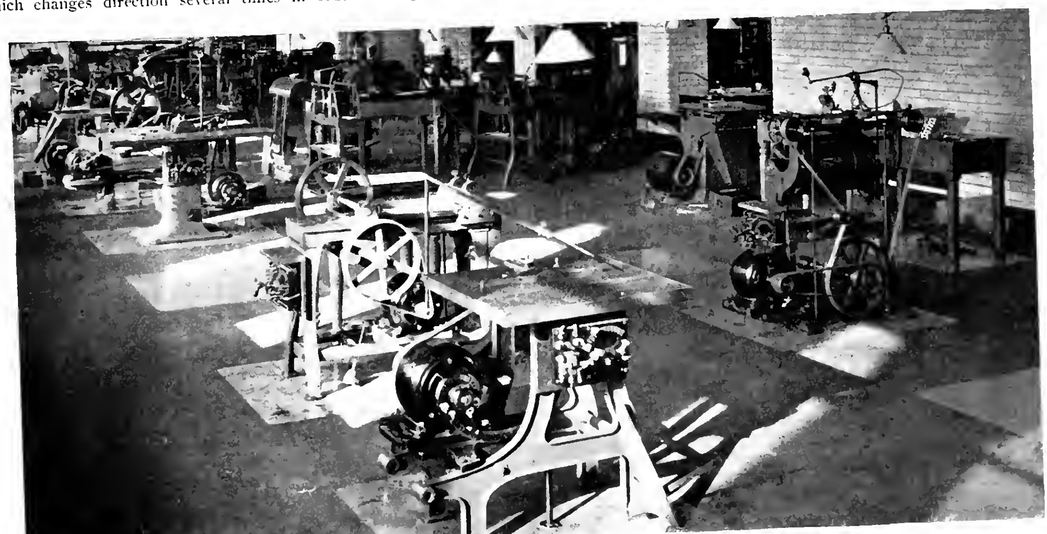

FIG. 42.—GENERAL VIEW OF ELECTROTYPE FINISHING APPARATUS.

strikingly indicated in this cut, where if they were to be group driven, their number and close spacing would make the problem an intricate one, particularly since it would be necessary to limit their positions to allow for straight belt lines. Figs. 31 and 32 illustrate this point most effectively, the first being a view taken in the old plant when the presses there shown were all belt driven from line shafting, and the second a line of presses as now set up in the new building. Even the photos show the effect of the increased lighting, and another benefit not indicated so clearly is the absence in the second case of dancing shadows cast by the moving belts across the work in the press to the annoyance and discomfort of the operators when attempting to scrutinize the type for faults.

It would, indeed, be difficult to enumerate all the motor drive in this branch of the office, but we may well supplement our cuts by Fig. 43, of a case shaver in the foundry, run by motor, and with a knife heated by electricity; Fig. 44, motor driven molding press in the foundry; and Fig. 45, showing the motor driven ruling machines in the bindery, the last appliances getting down to the use of electric power in very small modicums with motors of the fan class. The bindery includes, however, a great deal of heavy and ingenious machinery, all motor driven, upon which as much space might appropriately be expended as we have already given above to the press room equipment proper, the foundry, and other departments.

While this article has been in preparation, arrangements have been made for a further important addition to the printing press equipment in the shape of the new Hoe press to get out the larger edition now required of the "Congressional Record." According to the details which have been kindly furnished us by Mr. G. F. Read, of the R. Hoe & Company, of New York, the machine is for printing and folding the "Record," delivering the product in signatures of eight pages at the rate of 80,000 per hour, or sixteen pages at the rate of 40,000 per hour. It is constructed on the rotary principle, printing from curved stereotyped plates upon webs of paper supplied from two rolls, one at each end of the machine. After being printed the two webs are associated and led to a cutting and folding mechanism located midway in the length of the machine, from which the sheets are delivered upon moving aprons. The entire length of machine is 24 feet; height, 9 feet; width, 6 feet. The power required to drive the machine at speed is 30-hp, and a Crocker-Wheeler motor of standard type, making 825 r. p. m. is employed, placed below the folding and delivery mechanism upon the bed plate of machine. Another motor of 7½-hp, 875 r. p. m., is also used at times, when it is necessary to move the press slowly (about 6 per cent. of full speed), in order to "lead" the paper.

The means by which either motor may be used to drive is this:

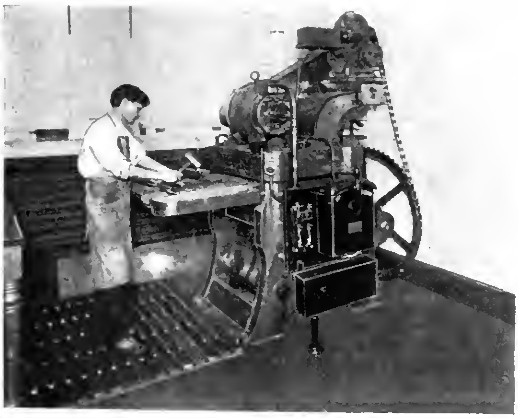

FIG. 44.—MOTOR-DRIVEN MOLDING PRESS IN FOUNDRY.

The armature of the large motor is coupled to a short shaft, on the opposite end of which is a rawhide gear pinion, in mesh with a large gear wheel on the outer end of the main driving shaft of the machine and which will run at 166⅔ r. p. m. Secured to the pinion shaft is a disc, carrying spring-seated pawls which are adapted to engage with the teeth of a ratchet wheel formed on the side of a gear wheel, mounted loosely upon the pinion shaft and driven through reduction gearing by the small motor.

With this arrangement, it will be understood that the machine may be moved at slow speed by the small motor only driving (through the reduction gearing and ratchet wheel) the pawls which are secured to the pinion shaft; and that when full speed is required the

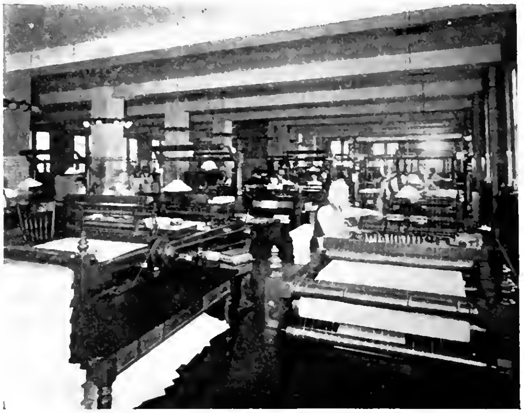

FIG. 45.—RULING MACHINES IN BINDERY.

large motor drives directly to the pinion shaft; the pawls at this time running away from the ratchet wheel and being thrown out of engagement with the teeth thereof by the centrifugal force. It is obvious that it is not necessary to continue running the small motor after the large motor has begun to drive. Located at various points about the machine are stations, each having a series of push buttons by which the full speed, slow speed or stoppage of the machine may be controlled.

Helium and Radium in London.

Somebody seems to have an object in stirring up old London in regard to radium. One recent story told of the tons of pitchblende refuse that had been thrown out by a chemical firm and used for road metal, and now comes another exciting suggestion of less solid, or perhaps a more liquid character. A cable dispatch from London of January 9th says gravely: "Will England in the near future develop a new industry? Is it possible that this old country has hidden away, deep down, mines of untold wealth of that invaluable element, radium? Such is the question many persons would like to have answered regarding London, where great quantities of radium are supposed to be buried beneath property which is too valuable to give over for the purpose of experiment. London's ancient city bath has come to the front this week because of the discovery that the old hot baths contain, in the waters they have been throwing up for centuries, no end of radium which has gone down the throats of invalid drinkers or has been disported in by bathers who must number millions. That excitement has been great over the discovery is shown by the columns which have been published in newspapers and letters discussing the wonderful find.

"It all came about in this way: The Hon. R. J. Strutt, son of Lord Rayleigh, while analyzing the waters of the bath, found, as he states in a letter which he sent to the Municipal Council of this city, that the waters contain radium in appreciable quantities. It was rather disconcerting, however, to have him state that he did not think the waters held enough to pay for extraction, though experiments promised interesting developments. As helium has been proved to be slowly evolved from radium, it is stated that helium, which is one of the deposits in the bath waters, owes its origin to radium which is buried somewhere under the bath. That it must exist there in plenty is believed widely, but how to get at it is one question, and another is, Could it ever be located? It may be miles beneath the earth's surface, but this discovery of radium has caused widespread interest in medical circles. Doctors have been surprised and sometimes puzzled by the cures wrought by the waters. One eminent local practitioner thinks that the presence of radium, even in infinitesimal quantities, in the springs may have wrought cures which seemed wonderful; but at present that can be a matter only for inquiry and investigation."

A Critical Review of Electrostriction.

By LOUIS T. MORE.

THE term electrostriction is applied to designate the mechanical strains that electrical forces produce in a non-conductor, such as glass or oil, which change in dimension or shape under their action. The phenomenon was first observed, or at least recorded, by Fontana in 1786. On charging a Leyden jar, which was filled with water, he noted an increase in the volume of the jar by means of the changed level of the water in a capillary tube inserted in it. The importance of this fact seems to have attracted little attention at the time, and no further observations are known until Govi, in 1864, confirmed Fontana's discovery in a more scientific manner, though he also wrongly attributed the action to the liquid in the condenser and not to the glass.

Two years later Duter corrected this mistake of Govi's and showed conclusively that the effect was due to a change in the volume of the glass and not to any change in the conducting fluid, which merely measured the strain. According to his results, the variations in the volume of the glass were proportional to the square of the difference of potential of the armatures and inversely as the thickness of the glass.

Shortly afterwards, Righi extended the experiments and increased their accuracy. For the first time, he employed glass tubes about a meter long, whose internal and external walls were coated with tin-foil. When the armatures of these condensers were charged, the tube lengthened proportionally to the square of the difference of their potentials and inversely as the thickness of the tube.

So the matter rested as an isolated fact, for, according to the theories of electricity then prevalent, the effect could be looked on only as an action of charged bodies at a distance, of the same inexplicable character as gravitation.

But when Faraday's conception of lines of stress in the electrified ether was better comprehended from the interpretation of Maxwell of the mathematical character of tubes of induction, it readily occurred to Maxwell and his supporters that electrostriction would serve for one of the fundamental proofs of their theory, as stresses in a medium might well be accompanied by strains in the matter involved in it, and it is from this time that the question has grown in importance and has been the subject of many experiments, hypotheses and controversies.

Maxwell's theory of displacement currents and of electrical stresses and strains in the luminiferous ether rests on four fundamental experiments, three of which were untried at the time the theory was formulated. These are:

1. A static charge displaced in space has all the electrical, electromagnetic and inductive actions of an electric current.

2. In a magnetic or electric field there are tensions along the lines of force and pressures at right angles to them.

3. Electromagnetic oscillations are transmitted with the speed of light.

4. The specific inductive capacity of a dielectric is equal to the square of its refractive index for light.

Of these four verifications, the second is the subject of this paper. Before considering it in detail, it is interesting to review how far they have stood the test of time and minute research.

1. We have for a proof of the first the famous experiment of Rowland with convection currents. An ebonite disc was charged and rotated at great speed near a magnetic needle, whose center was placed in the axis of rotation. The needle deflected to the right or left, according to the direction of rotation of the disc and in the same manner as a current of electricity flowing in the direction of rotation. Until very recently the experiment was regarded as conclusive. But Crémieu, who undertook the inverse problem, found no effect and questioned the results of Rowland's work. In the discussion which has ensued Crémieu seems to be the one in error.

The electromagnetic action of displacement currents was attempted by Röntgen in 1885. To produce this effect an ebonite disc was rotated from 120 to 150 times a second, on a vertical axis, between two parallel glass plates, A and B, whose internal faces were covered with tin-foil. The tin-foil on the upper glass plate, B, was grounded, and the sheet on the lower plate, A, was slit diametrically so as to form two insulated sectors. These two were charged with electricity of opposite signs by connecting them with the armatures of a charged condenser. The lines of force thus passed from the positively-charged sector of A upward to the grounded plate, B, through the movable ebonite disc and downward from B to the negative sector of A; consequently, the field was oppositely directed on the two sides of the medial slit in A. As soon as the ebonite disc was revolved, displacement currents were started, which were in contrary directions on the two sides of the slit. These currents were sufficient to deflect the lower needle of an astatic magnetic system suspended eccentrically to the plates; the lower needle being close to them and the upper one at a distance of 22 cm. Röntgen observed and measured these deflections, but the results are complicated by other causes, such as convection currents, thermoelectric effects, etc., and are not entirely satisfactory.

2. Stresses and strains in a magnetic field undoubtedly exist, as iron and other metals show unmistakable changes in length and cross-section when magnetized, which cannot be explained by any other cause.

Electrostriction or change in length of a dielectric in an electrostatic field was taken for granted by Maxwell from the results already described in this article. But recently, work of my own in this field makes it extremely doubtful if such an effect has ever been observed. It is, at least, certain that it is much more minute than was supposed.

3. It may be accepted that electromagnetic oscillations progress with the speed of light. It is even very generally admitted that light is but a manifestation of these oscillations.

4. Many investigators have endeavored to obtain the relation between the specific inductive capacity of a transparent dielectric and the square of its refractive index for light. In regard to liquids there is known to be a fairly close equivalence between the two, but the dielectric constant for solids is so complicated by extraneous effects that no sort of a relation has been found.

Before, then, Maxwell's theory can be established on these phenomena, they must be shown to be true beyond doubt, and this is far from being the case. Personally, I am not sure that electrostriction can be used as a criterion for this theory, as I can see no reason why there should not be stresses and strains in the ether in a field of force such as Faraday imagined, and that these stresses in the medium should necessarily produce a mechanical deformation in matter immersed in it. On the other hand, if a dielectric does expand, when charged, it would be a confirmation of the theory. The true and great importance of the question lies rather in the light it throws on the relation between matter and ether. This view is contrary to Maxwell's, as he evidently felt that electrostriction was a fundamental fact on which to base his theory, and the observations made up to his time warranted him in considering it as a striking confirmation. So also did Faraday, who, in paragraph 1297 of his "Experimental Researches," says: "The direct inductive force, which may be conceived to be exerted in lines between the two limiting and charged conducting surfaces, is accompanied by a lateral or transverse force equivalent to a dilatation or repulsion of these representative lines (1224); or the attractive force which exists amongst the particles of the dielectric in the direction of the induction is accompanied by a repulsion or a diverging force in the transverse direction." Maxwell is even more explicit. On page 165 of the first volume of his "Electricity and Magnetism," he writes: "The hypothesis that a state of stress of this kind exists in a fluid dielectric, such as air or turpentine, may at first sight appear at variance with the established principle that at any point in a fluid the pressures in all directions are equal. But in the deduction of this principle from a consideration of the mobility and equilibrium of the parts of the fluid it is taken for granted that no action such as that which we here suppose to take place along the lines of force exists in the fluid. The state of stress which we have been studying is perfectly consistent with the mobility and equilibrium of the fluid, for we have seen that, if any portion of the fluid is devoid of electric charge, it experiences no resultant force from the stresses on its surface, however intense these may be. It is only when a portion of the fluid becomes charged that its equilibrium is disturbed by the stresses on its surface, and we know that in this case it actually tends to move."

This stress along the lines of force as deduced by Maxwell is given by the formula, $p = \dfrac{K R^2}{8\pi}$, where p is the numerical value of the tension, K is the specific inductive capacity of the dielectric and R the electromotive intensity, or the strength of the field. Besides this tension there is a pressure of an equal amount in all directions at right angles to the direction of the lines of force. If these stresses in the ether are communicated to matter immersed in it, matter should lengthen along the lines of force and shorten at right angles to them.

The formula of Maxwell has been developed by later writers and perhaps the best attempt has been that of Dr. Sacerdote. To connect the actions of the ether and matter he introduces, in addition to the elasticity of the matter and its dielectric constant, the variation of the latter with pressure. If a long cylinder of the substance is charged by means of armatures adherent to its inner and outer faces, the expansion at right angles to the resulting lines of force is given as $\frac{\delta l}{l} = (a + k_1) \frac{K V^2}{8\pi d^2}$, where l is the length of the tube, d the thickness, K the dielectric constant, V the difference of potential which is equal to $R d$, a the inverse of Young's modulus, and k_1 the specific change of the dielectric constant with pressure, that is

$$k_1 = \frac{d k}{d p} \frac{1}{K}.$$

He makes a number of assumptions principally as regards k_1, and also in that he assumes no heat to be evolved by the charges and no mechanical deformation of the cylinder to be caused by the electrical attraction. The last two will be shown later to be of a size sufficient to account for all observed effects. And as for k_1, it has never been determined with any accuracy. "Indeed (I quote from my last paper), even its sign is a matter of dispute, some obtaining a positive value and others a negative one. It is introduced into the equation on the ground that the relation is a reciprocal one. If the dielectric constant of a substance increases with a tractile force applied perpendicularly to the lines of force, it is assumed, when a dielectric is charged, that the field of force should produce a tractile force, accompanied by a corresponding elongation. But it should be remembered that this coefficient is not yet determined, and even if it were the reciprocal relation may not exist. In a general way, the dielectric constant *is* greater, the denser the substance; it may well be that if a gas, or a solid to a less degree, were compressed, and the molecules thus become closer together, the dielectric constant might increase. It does not at all follow that the increase is accompanied by a repulsion of the molecules at right angles to the field, unless we make the assumption that an electrical charge produces in some manner a mechanical strain. If the dielectric constant is shown by experiment to increase with a tractile force, not because the molecules of matter are incidentally brought closer together, but because of the stress itself, then the reciprocal relation that a charge causes a strain perpendicularly to the field will hold, or vice versa. But until one or the other is indisputably proven, to introduce either one into the equation to prove the other is tacitly assuming the whole question of the mechanical relations between ether and matter."

The experimental work in recent years is due principally to Quincke, Cantone, Shearer, Wüllner and Wien, and myself. The work of Quincke is thorough, but deficient in accuracy. He experimented with small glass tubes, about a meter long, clamped horizontally, which were usually silvered on the inside and immersed in a conducting fluid for the other armature; the elongations were magnified by Oertling's mechanical lever and read with a telescope and scale. He also used glass thermometers filled with acidulated water and silvered on the outside, whose volume changes was measured by the rise or fall of the liquid in a capillary tube sealed to the bulb.

His results are that solids like glass expand in length perpendicularly to the lines of force; that this expansion is proportional to the square of the potential difference and inversely as the square of the thickness. For flint glass the expansion, reduced to unit dimensions, is $\frac{\delta l}{l} \times \frac{d^2}{V^2} = 2 \times 10^{-13}$, and for crown glass, 4×10^{-13}. But his results contain many discrepancies due mostly to heating, to irregularities in the shape of the tubes and thermometers and from the sagging which must certainly occur when fine glass fibres are stretched horizontally between two end supports. Heating was shown by the fact that the dielectric never returned to its original length when the electricity was discharged, and gradually increased in length while uncharged. He himself gives prominence to the fact that if a bent glass tube or one not uniformly thick be used, there is a large amount of distorsion due to the non-uniformity of the field. This irregularity must also occur when thermometers are employed, as it is naturally impossible to blow a bulb perfectly spherical, and also uniform in thickness. Quincke states "that thermometer No. 34 had a bulb of somewhat irregular shape and wall thickness, so that the inner portions of the bulb on electrification would be especially affected. It is, therefore, not comparable with the others, and is included only because it shows the greatest change of volume which I have been able to observe in glass." This thermometer showed an expansion of 68.36, where No. 9 of the same glass, of practically the same thickness, and at the same difference of potential, gave only 5.277. This great difference due to what he calls a "somewhat irregular shape and wall thickness," makes one wonder whether the expansion of No. 9 might not largely result from the same causes.

Prof. Cantone, alone and in collaboration with Sozzani, has published many experiments, beginning in 1888. He used cylindrical condensers and measured their changes in length by means of the shift in interference bands of light, reflected between two parallel mirrors, one of which was fastened to the end of the tube. The tubes were about 70 cm. long, 7 mm. in diameter and ranged from 0.045 to 0.2 cm. in wall thickness. The armatures were adherent to the glass and the greatest elongation was 2.6 bands, while most were less than one band. The elongations reduced to unit dimensions, average $\frac{\delta l}{l} \times \frac{d^2}{V^2} = 6 \times 10^{-13}$. This result is calculated from the deflections observed when the tubes were charged; the return, when the tubes were discharged, sometimes equalled the above, and was sometimes less than half. The time of charging also affected the amount of the elongation very much; but no law could be formulated, and no reasons are given for the time of charging determined on to give the correct value.

In spite of the carefulness which Cantone's experiments show, there are evidences that the values given are, at least, partly due to causes other than the one he ascribes them to.

In the first place, the amount of the elongation increases with the time of charging and to an unknown extent.

Secondly, they are partly due to heating of the tube. Cantone attributes the erratic return of the tubes to the heat evolved, and this varies between a complete return and a value of one-half. If so, surely part of the elongation in *charging* must be due to the same cause.

Thirdly, the armatures touch the glass, and this attraction will elongate the tube, using Poisson's ratio, approximately one-third the observed amount.

Fourthly, tubes of the dimensions given are flexible, rarely straight, and do not have a uniform wall thickness. All of these defects tend to strain the tube when it is charged, as the field is not uniform. The amount of this strain is large, and even with unusually accurate tubes it is difficult to avoid an apparent elongation greater than the supposedly true effect.

Unless these causes of a possible elongation are eliminated, the elongation observed is subject to criticism.

Very soon after these experiments were published and before I was acquainted with them, I published in 1900 my first paper, in which I came to the conclusion that glass did *not* elongate when it was charged, and the effects observed by others were due to extraneous causes. Dr. Sacerdote criticised the paper, pointing out Cantone's results which in his opinion were the only trustworthy ones, and wrongly interpreting a statement of mine, maintained that my apparatus was not sensitive enough to observe such small values. In a subsequent paper I corrected Sacerdote's error and proved that my apparatus could and did detect much smaller quantities. But not content with this I have gone over the work again, using apparatus of the same nature, but considerably more sensitive.

While the question was in this state, Dr. Shearer made a series of experiments on glass and rubber tubes, measuring their changes by interference methods similar to Cantone's. Although he observed elongations, he accounted for them by heating and slight distortions due to an unsymmetrical field, confirming my own results in full.

My own apparatus consisted of three coaxial tubes, 65 cm. long, the middle one, of glass, was the experimental tube, about 4 cm. in diameter and 2 mm. thick; the other two, of heavy seamless brass tubing, formed the armatures or were connected electrically to tin-foil armatures pasted on the experimental glass tube. The three were fastened vertically in a massive iron base. Great care was used to have them rigid and accurate in alignment.

The magnifying arrangement was an optical one. It consisted of a little three-legged brass table, bearing a vertical mirror. The legs were made of needles which had an effective distance between the points of 3 mm. One of them rested on the top edge of the experimental tube and the other two on the inner brass one, so that any relative change of length of the tubes tipped the table and mirror. A lens with a focal length of a metre brought the image of a fine horizontal glass thread, after reflection in the mirror, to a sharp focus at a metre's distance in front of the tube. Then the vertical movement of this image when the mirror tilted was observed by a cathetometer microscope, one division of whose micrometer screw head was equal to 0.002 mm. As a result, a change of length of 6×10^{-6} mm. in the experimental tube could be observed.

The observations recorded by others have been for glass charged by armatures adherent to it, but this arrangement is certainly faulty as the electrical attraction of these must compress the glass between them mechanically and so expand it perpendicularly to this direction or in the direction measured. The correct disposition is to separate the armatures from the solid dielectric and to fill the intervening spaces with a non-conducting liquid of as nearly the same dielectric constant as possible. If this precaution is taken the attraction of the armatures cannot affect the glass, and by having a liquid of nearly the same dielectric constant as the glass, the drop in potential between the armatures is nearly constant. With my arrangement I could employ both methods. The results, as given in my last paper, may best be summarized separately for the cases of adherent and non-adherent armatures.

ADHERENT ARMATURES.

1. When a tube is first charged it apparently increases in length about 15 divisions of the micrometer, or 90×10^{-6} mm. for a potential difference of 33,000 volts. If the tube is charged more slowly, for about a minute, the elongation is more than double, and a less time in charging diminishes the effect to a very small displacement.

2. With an increasing potential the elongation increases, but not uniformly, and a return to lower potentials shows a value much less than the original deflection for that potential.

As the armatures are adherent, we must make a correction for their mechanical attraction. According to Poisson's theory for the expansion of a solid perpendicularly to a compressing force,

$$\delta l = \frac{1}{E} \frac{K V^2}{8 \pi d^2} \acute{o} l.$$

where E = Young's modulus,
K = the dielectric constant,
V = the potential difference,
$\acute{o}$ = Poisson's ratio,
l = the length of the tube,
d = the thickness of the tube.

Substituting the proper values for these constants, the increase in length, for $V = 33{,}000$ volts, is 3 divisions of the micrometer. That is at least one-fifth the elongation when a tube is first charged and one-half for subsequent charges.

Again, a correction is to be made for heating. This effect was quite apparent, as after the glass had been once charged it never came back to its original length; it then when discharged began to elongate slowly for a long time. For example, a tube when the image was perfectly steady, was charged and then discharged, in five minutes the image showed an increase in length of 92 divisions.

A simple calculation shows that a rise in temperature of 0.017° C. will expand such a tube the entire 15 divisions of the micrometer, or the average initial increase of the tube for a potential of 33,000 volts. It is almost impossible to measure the heating of the glass itself, but I did measure the increase of temperature of a layer of oil which filled the spaces between the experimental tube and the two brass ones, placed there to prevent leakage. One end of a thermopile, made of a single iron-platinum couple, was immersed in the oil and touched the surface of the glass, while the other was kept in melting ice. When the galvanometer, which was included in the circuit, was steady the tube was charged and discharged ten times. The galvanometer indicated a rise in temperature of the surface of the tube of from 0.4° to 0.9°. This is greater than is required to expand the glass the observed amount, and will, in connection with the mechanical pressure of the electrodes, account for all the observed phenomena—both of elongation with the charge and slow increase after the discharge.

NON-ADHERENT ARMATURES.

For experimenting with non-adherent armatures, the tin foil was removed from the experimental tube and the inner brass tube grounded while the outer one was charged by a static generator to a potential of from 33,000 to 45,000 volts. In order that these charges should not leak away from the charged tube, a glass cap was fitted over the top and bottom of it. The spaces between the three tubes were then filled with pure lard oil, which had been carefully filtered. Although the dielectric constant of this oil is somewhat less than that of glass, it was the only fluid which would maintain so high a potential for long without excessive leakage. With this arrangement, using potentials which ended always by shattering the glass, *no deflection occurred.* The heating, as the leakage along the surface of the glass was practically stopped, was very much diminished and still more retarded. So much so that the tube could be charged, observed and discharged before the rise in temperature was sufficient to deflect the image to any extent. While one charge and discharge with adherent electrodes heated the glass in five minutes sufficiently to expand it 92 divisions, ten charges and discharges produced now in four minutes a deflection of only 42 divisions. That no elongation by the strain of an electrical charge occurred could not be due to any lack of sensitiveness or accuracy of the apparatus, as it was capable of recording changes much less than those recorded by others.

The experiments are to me conclusive either that glass is not affected at all by strains in the ether or else it is a vanishingly small quantity. And further, I have shown that the observations of others may be fully accounted for by extraneous causes which they did not eliminate. This effect must, if I am found correct, be withdrawn as a proof of Faraday's and Maxwell's theory.

One of the most convincing proofs that dielectrics do not elongate is the fact that as our apparatus and methods are refined the elongation constantly diminished until they are now practically vanishing quantities.

Since my paper went to press Wüllner and Wien have published in *Drude's Annalen der Physik* a very elaborate and exhaustive series of experiments on electrostriction. They unfortunately used Quincke's method of thermometers. For this purpose the glass is blown into a large spherical or cylindrical bulb with a capillary tube sealed to it. The expansion of the volume of the glass produces an increase in the content of the bulb and a consequent lowering of the fluid in the capillary. Their results naturally confirm those of Quincke, which have been pronounced unsatisfactory both by Sacerdote and Shearer, as well as by myself. The principal sources of error of this method are the unavoidable change of shape and volume of a bulb, which is not and cannot be a perfect sphere or cylinder when it is subjected to the forces of an electrical charge, the heating of the bulb which cannot be measured and the inaccuracies in reading the meniscus of a capillary water column which is charged or near a charge.

Their work, while it is remarkable for its thoroughness and the care which its authors took to avoid and discuss errors, cannot influence the question much one way or the other, as they unfortunately adopted a defective method.

Measurement of Current by Copper Voltameter.

By J. L. Dickson.

LET us assume that it is desired to measure the current of one 110-volt incandescent lamp and that we have no ammeter with which to accomplish the result, but that near at hand is a copper voltameter suited for the purpose.

In the diagram let G represent a tangent galvanometer; C a com-

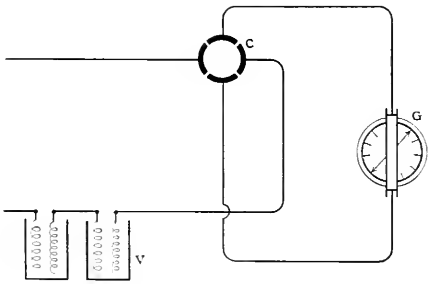

DIAGRAM OF CONNECTIONS.

mutator, which is used to reverse the current; V a copper voltameter consisting of two cells connected in series. The voltameter contains two copper wire coils, one the gain coil, the other the loss coil; the gain coils are shown in the diagram as being the smaller ones.

The gain coils should be weighed very accurately and placed inside the loss coils; then both coils should be placed in jars containing $CuSO_4$ (copper sulphate); this solution being made by dissolving one part (by weight) of crystals of copper sulphate in five parts (by weight) of water, and adding 1 per cent. of strong H_2SO_4 (sulphuric acid), this excess of acid serving to dissolve such impurities as may exist in the copper sulphate.

Now, let the apparatus be connected in series as shown in the diagram, the exact time taken and the current turned on. Allow the current to flow about 45 minutes, reversing its direction through the galvanometer, G, every five minutes by means of the commutator, C. Then remove the gain coils and dry them by dipping in distilled water, roll them on filter paper until only a thin film of water remains, then insert them in strong alcohol; dry on filter paper and weigh as soon as dry.

Suppose the following readings were obtained during a certain test:

Before run coil weighed.	After run coil weighed.	Time in min.
65.47 grams	65.87 grams.	45

From the above data the strength of the current in amperes can be calculated.

Let w_1 = the original weight of gain coil,
w_2 = the weight after current has passed,
t = time in seconds during which the current flows,
I = strength of current in amperes,
.000329 = the electrochemical equivalent for copper.

$$\text{Then } I = \frac{w_2 - w_1}{.000329\, t}, \text{ or}$$

$$I = \frac{65.87 - 65.47}{.000329 \times 45 \times 60}, \text{ or}$$

$$I = .45 \text{ ampere.}$$

This is the amount of current taken by one incandescent lamp at 110 volts. To determine H and the galvanometer constant, let us again assume that the average angle deflection of the galvanometer, G, was noted to be 60° when the current was flowing. From this the "reduction factor" of the galvanometer can be computed as follows:

The current equals the tangent of the angle of deflection multiplied by the constant, or algebraically it is:

$$I = K \tan D \quad (K \text{ being the constant}).$$

Substituting the values assumed, we have $.45 = K \times 1.73$, or

$$K = \frac{.45}{1.73}, \text{ or } K = .2601.$$

Therefore, "reduction factor" is .2601.

The general equation of the tangent galvanometer is:

$$H \tan \phi = \frac{2\pi\, n\, I}{r},$$

where H = horizontal intensity,
$\tan \phi$ = tangent angle of deflection,
n = number of turns on galvanometer,
I = current in absolute units,
r = radius of galvanometer.

$$\text{Let } n = 20 \text{ and } r = 14.85, \text{ then } 1.73\, H = \frac{2 \times 3.14 \times 20 \times .45}{14.85 \times 10},$$

or $H = .22$. This gives the horizontal intensity at a certain assumed point.

Rather Dear Lighting.

The annual report issued by the managers of the municipal lighting plant of Taunton, Mass., shows a cost per arc of $120.77 per year. The number of street lights operated was 247, and the number of hours burning was 2,987. The attempt is made as follows to put forth a better showing by Mr. Abner Coleman, the manager: "In figuring the cost of the street light, to the city, under the rule of the Board of Gas and Electric Light Commissioners, the cost is $120.77 per light per year. The cost is obtained by taking for one side of the account the total cost of interest, the amount charged off for depreciation, and the total cost of maintenance, from which is deducted the total income from light and power sold, less any increase of material on hand at the end of the year. Now, in figuring the total cost of interest, it includes that of the interest on the $175,000 bonds issued for the new station, and as this part of the equipment has earned but very little, it does not seem hardly fair to add to it the cost of street lights this year, so that deducting the amount of $6,125 from the total would show a cost of $96 per light. Of the total amount of the increased cost of coal, about $4,500 of the amount was a direct addition to the cost of the street lights, and added about $18.22 to the cost of each light for the year."

The Grounded Neutral.

By R. S. Hale.

Whether the grounded neutral is an advantage, as now seems to be the general opinion, or whether it is a disadvantage as some people would still try to make us believe, it is a condition and not a theory that confronts us in the Edison three-wire direct-current systems in the great cities of the country. The neutrals of these systems are so thoroughly grounded that it would probably be impossible to insulate them even if it should be attempted. Since they are grounded the electrical condition is different from the small insulated two-wire or three-wire systems with ground detectors on the switch board that formed the earliest type of electrical distribution, and why should we not take advantage of this difference? There are four ways in which the wiring on a three-wire system with grounded neutral can be done more cheaply and as safely or more safely than at present and these are as follows:

First, the use of single-pole switches instead of double-pole; second, the use of single-pole cut-outs instead of double-pole; third, the consolidation of the neutrals when there are several circuits side by side; and fourth, the use of a cheaper insulation or no insulation on the neutral.

First, in regard to the switches, let us consider the electrical condition of the circuits when in use and when disconnected. We need consider only the plus side since the conditions on the negative side will be practically the same.

When the circuit is connected the plus side is at 110 volts at all points (neglecting drop), the neutral is at zero potential at all points (again neglecting drop) and is solidly connected to the ground in the street. Inside the house the neutral is, according to present practice, insulated, but when the circuit is in use the neutral inside the house is connected to the ground through the switch, and outside neutral.

When the circuit is not in use, the neutral inside the house is (if a double-pole switch is used) disconnected from everything, and there is a possibility that it might be crossed with some high potential circuit, in which case this cross would not be discovered until some one touched either the neutral or positive inside the house, or until the circuit was again put in use. This obviously is a more dangerous condition of affairs than if the neutral inside the house were connected to ground at all times. The argument is easily recognized as the usual one in favor of a grounded neutral, and while a cross with high-tension wires is less probable inside the house than out, yet it is a possibility and should be guarded against if there is no accompanying disadvantage in the means used for protection.

That there is no disadvantage in having the neutral inside the house connected to ground at all times, is easily seen when we remember that the water pipes and gas pipes inside the house are solidly connected to ground at all times and hence also to the neutral wire in the street; and that if the neutral inside the house were connected to ground at all times it would be in exactly the same electrical condition as these same bare pipes.

The advantage of breaking the circuit at both poles, as with a double-pole, instead of at a single-pole switch, might seem to be in favor of the double-pole switch, but a single-pole switch with a break distance equivalent to a double-pole switch is much cheaper than the latter, and takes up much less room and is much less liable to get out of order. In case the neutral should be accidentally grounded inside the house, the positive side of the double-pole switch is the only side that breaks the current, while a single-pole switch of break distance equivalent to the double-pole would always be fully effective.

Next in regard to the cut-outs. If a double-pole cut-out is installed, both sides are effective in case of a short circuit between the two wires of the circuit. It is only the positive cut-out, however, that is effective in case of a short-circuit between the positive wire and the ground, which gives a worse short-circuit than between the two wires. Hence, if the cut-out on the positive side is sufficient for the worst case, why go to the expense of a cut-out that will be no more effective and will operate only in a few of the less dangerous cases? If, however, it is felt that the second cut-out is desirable, why not put it in series with the first cut-out, but put both on the positive leg where both will always be effective? It should be noted that if there should be an accidental ground on the neutral inside the house, the neutral cut-out is of no use whatsoever.

Third, in regard to consolidation of neutrals, frequently two circuits will be run side by side, as for instance the circuit for the public lights in the hall of a building and the circuits for the tenants. At present separate neutrals are run for each of these. Two No. 14 wires, however, cost much more than a single No. 10, which is rated at the same carrying capacity as the two smaller wires, and would operate much better, since there would be less drop in the neutral in case of unbalancing of either circuit, and would be better in practically every way.

There is, of course, one case in which the single-pole switch or single-pole cut-out, etc., might cause trouble, but it is a case which never occurs in house wiring, and should never occur in any wiring. The case referred to is when it is attempted to save copper by using a neutral smaller than the others. In such case opening the single-pole switch or blowing the single cut-out might throw a current on the neutral greater than its carrying capacity. Even in this case the cut-out on the neutral is a questionable advantage, since if one side of the circuit should be so overloaded as to blow the neutral fuse only, then nearly the whole pressure between the outers, say 150 or 200, or even 220 volts might be thrown on one side of the house wiring, and would be fully as dangerous a condition as if there had been no neutral fuse.

Fourth, in regard to the use of a cheaper insulation or bare wire for the neutral, in the old-fashioned systems of insulated circuits there was as much reason for insulating the return as the outgoing wire. In the modern system, however, with grounded neutral, the electrical pressure on the neutral can never be over a few volts, hence a much cheaper insulation gives an equal factor of safety for all purpose. In fact, when we remember that the gas pipes and water pipes and steam pipe system is in exactly the same electrical condition as the neutral, since they are solidly connected to the neutral outside the house, there would seem to be but little argument for insulating the neutral so carefully inside the house.

The insurance rules were made up at the time when the insulated systems were the rule, and their requirements for double-pole switches, double-pole cut-outs, separate neutrals for all circuits and for complete insulation on the neutral inside the house are a relic of the old days. The requirements for double-pole switches and double-pole cut-outs perhaps had a basis also in the added safety of an extra break on the switch, and an extra fuse to protect in case of some short circuits; but as has been shown above, the same safety can be secured more efficiently and cheaper by putting the extra break distance and the second fuse on the positive wire. That the insurance rule is merely a relic of the old days and is not based on any sound insurance or electrical reason is shown by the other insurance rule that does permit a single-pole switch on circuits carrying a small number of lights, with, however, no rule as to whether this switch shall be placed on the neutral or on the wire that has the current at the full main pressure. If such single-pole switch is placed on the main wire, the situation is just as recommended above, and the only reason for not extending it to larger circuits would seem to be the question of an efficient single-pole switch, which can be easily taken care of at a less expense than the present double-pole switch. If, however, the single-pole switch on these small circuits be placed on the neutral, as in allowed by the present rules and as is frequently done, then we have a very dangerous condition of affairs, since when the switch is open the ordinary tests, as for instance, screwing in a lamp, would indicate no current on the circuit, while grounding any part of it, either main wire or neutral, would give at least a spark and in some cases a short-circuit.

It is suggested, therefore, that with a view to greater safety and a very considerable saving in expense, that the insurance rules should require that in all connections to any three-wire system with grounded neutral, the neutral wire should be a solid connection at all points with no cut-outs or switches whatsoever, from the neutral wire in the street up to the lamp or current consuming device.

In order to make the switches and cut-outs equally efficient with the present installation in all cases (they would be much more efficient in most cases) it might be required than when the neutral is thus made solid, then on 110-volt systems only the switches and cut-outs now allowed for 250-volt systems be allowed, and that on 250-volt systems only the switches and cut-outs now allowed for 500 volts be permitted.

The rules should also be changed so that whenever a neutral wire is installed under such conditions that the maximum difference in pressure between it and ground does not exceed, say, 10 volts (this would be due only to drop) then only such insulation be required as is now required on bell wiring and similar systems with a corresponding maximum potential.

These changes will, as has been shown, give at least equal safety to the present rules, and in some cases be much safer. They will reduce by a considerable percentage the cost of wiring, which is still the greatest obstacle to the introduction of electric light. Therefore why cannot the electric companies and insurance companies arrange to take advantage of the situation as it actually exists, rather than cling to obsolete rules based on conditions that are obsolete for all the great electric installations?

In regard to this matter, I may say that I recently installed an isolated plant, and for this installation I obtained as a special case from the insurance office that had jurisdiction permission to use grounded neutral, single-pole switches, single pole cut-outs and to consolidate the neutral in several places, thereby saving in all several hundred dollars. The question of using a bare neutral was also spoken of, but in this case of factory work the difference in cost between bare wire and the ordinary wire permitted for all the work was so slight that I did not press the point. If rubber-covered wire had been required for the main wires, I think that I could have obtained permission to use a much cheaper grade of wire for the neutral. This installation has given no trouble in any way that I have heard of.

Blockmann Radio-Telegraph System.

By A. Frederick Collins.

It is surprising yet none the less true that nearly every improvement in wireless telegraphy may be traced back to the original researches of Heinrich Hertz, on the action of electromagnetic waves in air. This is again strikingly illustrated in a new system of radiotelegraphy recently patented by Georg Friedrich Rudolph Blockmann, of Kiel, Germany.

In this recent addition to the art of wireless transmission Blockmann has made use of a fundamental principle discovered by Hertz, namely, the refraction of electric waves through an insulating medium; but before examining into the practical and commercial possibilities of the German inventor's apparatus a review of his lamented compatriot's remarkable discoveries in electric radiation will be useful by way of introduction.

Hertz, in 1888, published in *Wiedemann's Annalen* 36[1] a paper "On Electric Radiation," in which he described a series of experimental results in the production and propagation of free electric waves. The apparatus he devised was similar to that used by him for producing longer waves, except that its dimensions were greatly reduced, and the oscillator in consequence radiated much shorter waves than in his preceding experiments.

The oscillator consisted of two brass rods, each 13 cm. in length, placed in a line, the abutting ends, forming the spark-gap, being fitted with brass spheres 4 cm.; this radiator was provided with its initial energy from the terminals of a small induction coil, giving a maximum spark of 4.5 cm.; three storage battery cells supplied current to the primary winding or inductor and for the experiments in this case the spheres of the spark-gap were brought to within 3 mm. of each other. The detector was a copper wire 1 mm. in thickness bent in a circular form, but having a diameter of only 7.5 cm.

One of the terminals of this resonator ended in a brass sphere 5 mm. in diameter, whilst the opposite terminal was provided with a screw adjustment, so that a spark-gap of micrometer dimensions could be obtained. Now with this apparatus Hertz was enabled to produce the electric ray, which may, without considerable error, be considered the path of the wave. It was by means of these distinct rays of electric force that this distinguished savant reproduced all the elementary experiments heretofore regarded as belonging strictly to the realm of optics.

The account he has given of the amalgamation of the electromagnetic theory and the physical demonstration thereof is exceeded in interest only by the beautiful manner in which he showed the consolidation of electric forces and those of the optics of light, and to these reasons may be attributed the scientific popularity into which wireless telegraphy instantly sprung on its introduction in 1897.

With the apparatus described above, Hertz first proved that the electric forces emitted were identical with light emanations and radiant heat by demonstrating the rectilinear propagation of the ray. This was accomplished by interposing a sheet of zinc at right angles to a line joining the parabolic mirrors when an electric shadow as complete as that presented by light was evident. Again he found that insulators such as wood, rosin, pitch, etc., do not in the least interfere with the passage of long electric waves through them, but that all of the metals (conductors) would intercept them. The test proved that electric waves like light have a rectilinear motion in a homogeneous medium.

The polarization and reflection of Hertz's electrically emitted ether wave does not concern the system of Blockmann, but it may be stated merely in order to progress logically to phenomena which do have a bearing on it. By interposing a screen or grid, made by stringing parallel wires over a wooden frame, Hertz was enabled to observe all the optical manifestations attendant upon the polarization of light by microscopically lined crystals.

That the waves could be reflected was long known to Hertz, and in the admirable apparatus he devised the data he obtained in his previous experiments were made use of and parabolic mirrors were provided, first to emit the incident rays and second to make these rays converge and concentrate them on the arms of the resonator. Based on this principle, Marconi designed his earliest wireless apparatus, but in the Blockmann system the reflection of the waves plays no principal rôle, although the fact that the waves may be reflected is taken advantage of in a secondary manner, which will be indicated presently.

The refraction of light as the bending of the luminous ray when passing from one medium into another is called, is familiar to everyone, but to attempt the experimental demonstration of refracting an electric wave, say a meter in length, would have surely astounded the mind of a lesser genius than Hertz. In order to find out, as he puts it, whether any refraction of the ray, from his oscillator, took place in passing from air into another insulating medium, he had a large prism made of hard pitch.

The base of this prism had two equal sides each of which measured 1.2 meters and having a reflecting angle of nearly 30°. The height of this great prism was 1.5 meters and it weighed 1,200 pounds. Its refracting edge was placed vertically, so that when an electric wave approached the side of the prism its lower end would strike the surface of the pitch first and enter it; then, since the velocity of electromagnetic waves is less in denser insulating mediums than in air, the lower end of the wave is retarded until finally the whole wave has entered the prism when the change of wave front has changed the direction of the ray in the pitch.

The wave now progresses in a straight line through the homogeneous mass until its upper end emerges first, and, acquiring the accelerated speed of light waves in air, namely, 186,500 miles per second, the wave by the time the lower end has left the prism has been bent out of the line of propagation and the ray is refracted from the perpendicular. This is precisely what Hertz anticipated, and this is exactly what actually occurred. The waves were refracted, the ray was bent out of its normal line of propagation and to the mind of Hertz and to the satisfaction of every living physicist all doubt as to the identity of light, radiant heat and electromagnetic wave motion was removed.

Now, the certain new and useful improvements in wireless telegraphic transmitting and receiving apparatii, as invented by Georg F. R. Blockmann[2] is the practical outcome of the foregoing experiments of Hertz in refracting electric waves. Likewise, it is an example of how every niche in the art of wireless transmission is rapidly being filled in. The advantages of the heliograph in signalling is well known and to those who have had occasion to use it its objectionable features are even better known. Blockmann has nicely filled in the gap between the visible light signals of the heliograph and the invisible signals of the wireless telegraph.

Like the former and unlike the latter signals may be transmitted in any direction, but unlike the former and like the latter its rays may be sent forth in cloudy weather and at night equally as well as in the bright sunlight of day.

His invention, as indicated in a recent patent specification, consists of a transmitting and receiving apparatus, each of which are contained in a metallic box. The vertical sectional elevations, *I* and *II*, Fig. 1, and the side elevations (Fig. 2) gives an excellent idea of the principles underlying his system. The transmitter, *I*, comprises a metallic chamber for the purpose of intercepting and pre-

[1] Reproduced in Hertz' "Electric Waves," translated by D. E. Jones.

[2] U. S. Letters Patent 736,483.

venting the passage of electric rays into the interior chamber, except through the lens, *h*, which may be constructed of any suitable electric wave refracting material, such as rosin, wax, pitch, etc.

The casing or chamber is made large enough to not only include all the instruments, but may be virtually a station so that an operator may conveniently work the apparatus from the inside. However this may be, the source of e.m.f., as a battery or generator, *d*, a Morse key, *e*, for breaking up the circuit into the Continental code, the induction coil, *g*, with its attendant interrupter, *f*, and an oscillator or radiator, *c*, is contained therein. The latter is subsequently enclosed in a metal casing placed back of a tubular metal cone, having fastened in its larger diameter the lens of insulating material, *h*.

The chamber is pivotally mounted on a suitable support, *a*, so that it may be turned in any direction in azimuth; the lens, *h*, with its tube and oscillator, is also supported by pivots and may be moved through an arc of 30° vertically; by the compound movements of the lens and chamber it is possible to turn the lens in any direction, both in azimuth and altitude.

Blockmann points out that the same effect may be obtained by the suspension of the chamber from gimbels, as in the searchlight or in the manner of mounting turret guns. In his patent drawings the inventor shows the receiving chamber, *II*, also made of metal mounted above the transmitter, *I*, as indicated in Fig. 2, and arranged to follow the compound movements of the transmitter by means of the levers, t_1 *t*, and the connecting rod, *u*. It is obvious, however, that the sending and receiving chamber may be operated independently of each other.

The general arrangement of the transmitter and receiver are similar. In the focus of the two, *l*, of the receiving chamber is placed the ray detector, *m*, in the form of the usual coherer and the other appliances for receiving a message; these comprise the regulation tapper—not shown—the relay, *n*, in series with the coherer, a local cell, *o*, and a second local circuit, including the tapper, Morse register, *r*, and battery, *p*, for operating them. This apparatus may, of course, be replaced by the American type of receptor using instead an auto-coherer and a pair of head telephones. One of the strongest features of the new system is its applicability to firing mines by electricity, when the key of the transmitter may be made to close and remain so for a predetermined period of time. A correspondent from Berlin has communicated to the writer the interesting news that the German Government is now testing the merits of the system for specialized classes of work.

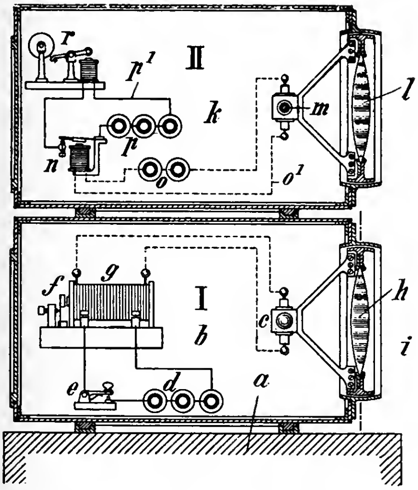

FIG. 1.—RADIOTELEGRAPH SYSTEM.

To facilitate the directing of the lenses, small finding telescopes—called finders—are rigidly mounted on the levers in front of graduated and arcuated bars, *v*, and the flexibility of the system makes it especially commendable for serving a greater variety of purposes and in a more exact manner than is possible with the ordinary wireless telegraph.

The range of Blockmann's apparatus is not nearly so great as with the grounded oscillator and resonator systems, and, therefore, excludes a large amount of uncertainty due to atmospheric changes to which the older systems are subject, and having no high masts to render its position conspicuous and as an arbitrary method for obtaining selectivity it is certainly a success.

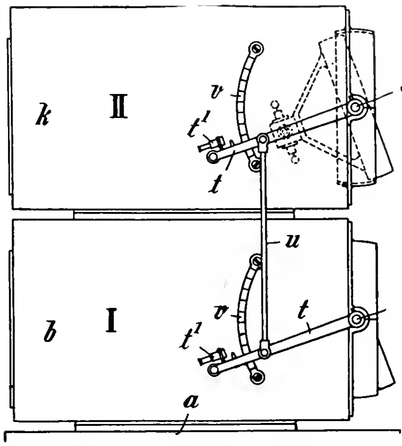

FIG. 2.—RADIOTELEGRAPH SYSTEM.

Blockmann does not limit his invention to the simple convex lens nor to any specific material for their construction, but broadly states that all methods known to optics for the intensification, enlargement and concentration of luminous rays such as compound lenses, etc., is embraced in the scope of his present apparatus for electric ray telegraphy, all of which is an interesting practical application of Hertz's fundamental observations.

Electric Traction in Italy.

Mr. Richard Guenther, the United States Consul-General at Frankfort, Germany, makes notes of the following: "The Frankfort *Journal of Commerce* states that electric propulsion by means of accumulators on the Italian Meridional route has not proved a success. The management of the road has, therefore, been authorized to discontinue this electric system on certain lines and to replace it by steam.

"The electric system, however, by trolleys over the 90-odd miles of the standard-gauge railroad along Lake Como has met all requirements. Some days ago a meeting of interested parties took place at the instance of the Chambers of Commerce of Milan, Lecco and Chiavenna, which resolved to request the government to immediately establish the trolley system upon the lines of Lecco to Milan. The results with the electric system with a third rail over the 45 miles of the standard-gauge Milan-Varese-Porto Ceresio Railroad have been entirely satisfactory. The traffic on this line, which connects Milan with Lake Lugano, has increased surprisingly on account of the cheaper rates, number of trains and quicker time. The management of the road is perfectly satisfied with the financial result.

"The Mediterranean Railroad contemplates the extension of the electric system with a third rail over the lines Verese-Laveno-Gallarat-Sesto Calende-Arona, so that then Milan will be directly connected with the upper Italian lakes by four electric standard railroads."

Distance No Object.

At a meeting of a scientific society at Strasburg, Germany, on January 9, according to press dispatch, Prof. Braun, inventor of the system of wireless telegraphy named after him, stated that recent discoveries and improvements made the question of distance in etherography of no importance.

Methods of Signaling and Operating in Telephone Exchanges.—IV.

By Kempster B. Miller and Charles S. Winston.

IV. TOLL CONNECTIONS.

Methods of handling toll connections are much more diversified than those by which connections of a purely local nature or those between two subscribers in the same exchange are brought about. The problem is different and more complex, as the requirements are more exacting and difficult of fulfilment, and many factors enter which need not be taken into consideration in handling local connections. As a result the service of an increased number of operators is involved in making a toll connection and a more or less complex system of accounting must be put into effect.

In toll work the call is nearly always for a party in a distant city or town whose name and address, together with his telephone number (if he has one) must be taken, as must also in most cases, the same data concerning the party calling. This necessitates a written ticket being made out that serves not only as a memorandum to the toll operator in bringing about the connection but also as a basis of the toll charge. As the time of the conversation and the predetermined rate between the points concerned determine the amount of the charge for any conversation, the measuring of the time elapsed from the moment when the parties are actuallly brought together, until they release the toll line, is naturally important, and adequate means must be provided for its accomplishment.

An entirely different class of work on the part of the operators is required which necessitates special operators trained in this particular line. The system should be so devised that these toll operators may co-operate with the local or subscriber's operators without in any way making the work of these latter operators special or out of the ordinary. A poor toll system will do much to hamper the work of the local operators, thus reducing their efficiency and increasing the cost of operation; but of even greater importance a poor toll system will cause a direct loss of revenue by the delays during and between conversations. The greatest investment of money in a toll line system is in the lines themselves, and the earning power of toll lines depends (after the rates are fixed) on the proportion of the time they are kept busy, and this, provided the traffic is good, depends largely on the speed in making up the circuits and getting the parties together.

It is evident that there are three general classes of connections through a toll board; "Local to Toll," where a local subscriber calls through the multiple board for a toll connection; "Toll to Local," where a call is received over a toll line for connection with a local subscriber; and "Toll to Toll" or "through" connections where a call is received over one toll line for connection with another.

KELLOGG TOLL SYSTEM A, USING RECORDING OPERATOR.

The Kellogg Switchboard and Supply Company has two standard methods of handling calls between toll and local subscribers. Wherever the toll board is of considerable size, or, generally, wherever the toll lines are multipled throughout the several sections of the toll board, it is customary to provide, in addition to the regular toll line positions, one or more positions known as recording operator's positions and, at the local multiple switchboard, one or more positions known as incoming toll trunk positions. The recording operator is concerned only with local to toll calls, while toll trunk operators, or toll switching operators as they are often called, have a hand in making all connections between toll and local subscribers. At night, or whenever the toll business is light, it is customary for the recording operator to handle all business at the toll board, and on this account it is the usual thing to place within the reach of the recording operator's position a multiple of all toll lines and a multiple of the toll trunk lines.

Each toll operator's position is equipped with a sufficient number of two kinds of cord circuits: toll to local, used for making all connections in either direction between a local subscriber and a toll line; and toll to toll, used in connecting two toll lines.

Each toll to local cord circuit includes a repeating coil and has on its local side a supervisory lamp adapted to be placed under the control of the subscriber, this side being adapted to common battery work. The toll side is adapted to magneto signaling, and has bridged across it a clearing out drop.

The toll to toll cord circuits have no repeating coils, and in addition to the usual listening and ringing keys a clearing-out drop is bridged across as in the ordinary magneto cord circuit.

Between the recording operator's position and the subscriber's operator's positions on the local multiple board extend a number of "recording toll trunks," each of these terminating in a jack and a lamp on the recording operator's position, and on the multiple board in jacks multipled through all the sections in the same manner as regular subscriber's lines. By these recording toll trunks the calling subscriber is originally put in communication with the recording toll operator.

The recording operator has a number of listening cords to enable her to receive instructions over the recording toll trunks; and in addition to these she has for night work a number of toll to local and toll to toll cords, for performing the ordinary duties of a toll operator.

When a local subscriber desires a toll connection, he will signal his operator at the local multiple board in the ordinary way, and in response to her question will state that he desires a "long distance" or toll connection.

Upon receiving a call for a toll line the subscriber's operator will then test the multiple jacks of the recording toll trunk circuits until she finds one which is not in use; and will then insert the calling plug associated with the answeing plug, which is already in the answering jack of the calling subscriber, into this trunk jack. This act will light the lamp associated with the recording toll trunk at the recording operator's position on the toll board. The calling supervisory lamp at the multiple board will not light, and thus the recording operator will be given entire charge of the connection. The recording operator will plug into the recording trunk jack with one of her listening plugs and, speaking directly to the calling subscriber,

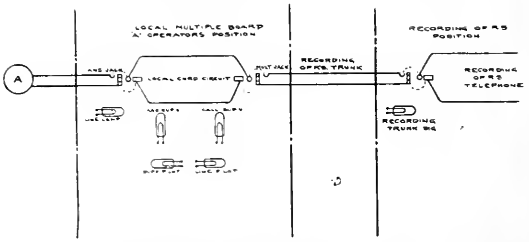

FIG. 6.—SHOWING CONNECTION BETWEEN RECORDING OPERATOR AND CALLING SUBSCRIBER IN KELLOGG SYSTEM "A."

find out whatever information is needed for making the connection. The connection thus established between the calling subscriber and the recording operator is shown in Fig. 6.

With the information thus obtained from the calling subscriber the recording operator will make out a ticket noting the numbers and necessary information to identify the calling and the called subscribers. She will then tell the calling subscriber to hang up his receiver and wait until called, and she herself will withdraw the listening plug from the recording toll trunk jack. When the calling subscriber hangs up his receiver, the answering supervisory lamp at the multiple switchboard will light, and when the recording operator withdraws the listening plug, the calling supervisory lamp also will light, and the operator at the local board will remove the connection.

The connection so far established is thus entirely destroyed, it having been made merely for the purpose of conveying the order directly from the calling subscriber to the recording toll operator. The final connection between this subscriber and the toll subscriber will, as will be seen, be made through an entirely different channel.

It will be noticed that the work on the part of the subscriber's operator was in this case regular, and that the action of her supervisory signals conveyed the same meaning to her as in the case of any purely local connection.

The method described, of selecting the trunk to the recording operator merits attention. It is one of the few cases where it is found better to have the operator at the originating or outgoing end of a trunk test for a free trunk rather than have the operator at the distant or incoming end designate the trunk by order wire. There is good reason for this apparent departure. In toll work, in order to avoid mistakes, and to relieve the "A" operator of special work, it is best to have the calling subscriber give his order directly to the operator at the toll board. There is, therefore, no need of order wires. Moreover, it would confuse the recording operator while making out a ticket for one connection, to be interrupted by receiving order wire instructions from subscriber's operators. Under the arrangement spoken of, the recording operator may make out the tickets of each waiting subscriber in turn, accuracy in this respect being of paramount importance, warranting some sacrifice of the calling subscriber's time.

After the recording operator has made out the ticket she will pass it to one of the toll line operators, who will test a multiple jack of the desired toll line with the toll plug of one of her toll to local cord circuits, or find out by other means whether the toll line is busy. In case it is not busy, she will insert this plug into the jack and ring up the distant subscriber, or the operator or operators at distant exchanges, necessary to make up the connection. The connection may be ordered up, as is frequently the case, by telegraph over separate lines, or over the telephone lines duplexed.

As soon as the connection has been made up at the toll board and the called-for party has been secured, the toll operator will speak over an order wire to the toll switching operator at the local multiple

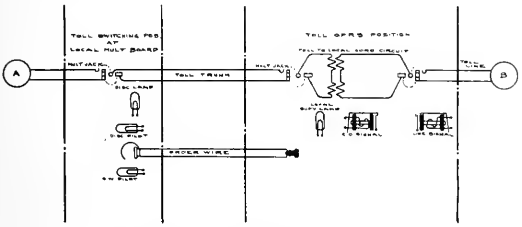

FIG. 7.—SHOWING CONNECTION BETWEEN TOLL AND LOCAL SUBSCRIBER IN KELLOGG SYSTEM "A."

board and give her the number of the subscriber who previously called for toll, and tell her to put up a trunk connection. In the building up of this, the final connection between the calling local subscriber and the toll subscriber, reference is made to Fig. 7.

The trunk lines, leading from the toll board to the toll trunk operator's position on the multiple board, end in plugs at the latter position and in jacks at the toll board, these jacks being multipled through the toll sections. The toll trunk operator will designate the trunk line which is to be used, and, *without testing*, insert the plug of this trunk into the multiple jack of the subscriber designated. At the same time the toll operator will also, without testing, insert the local plug, which is associated with the toll plug already in the toll line jack, into the multiple jack of the toll trunk line. If the local subscriber's line is in use, the supervisory lamp in the local side of the toll to local cord circuit at the toll board will not light, but if the line is not in use, this lamp will light. Thus the supervisory lamp acts as a ringing signal for the toll operator, enabling her to ring the local subscriber who made the call, the instant he hangs up his receiver, in case he was using his telephone on another connection while waiting to be called by the toll operator.

If the toll switching operator at the multiple board was obliged to test before plugging into the multiple jack, the operation would not be as rapid and the toll operator would be very much delayed, as it would be necessary for her to keep reminding the toll switching operator to keep on testing until she found that the line was not in use. As soon as the toll operator receives the signal, as described, she will throw the ringing key and ring the bell of the local subscriber.

After the incoming toll trunk operator has inserted the trunk plug into the multiple jack, the toll operator has entire charge of the connection. At the end of conversation the toll subscriber will, by turning his hand generator, throw the clearing out drop at the toll board, or this may be done by a distant toll operator; and the local subscriber, by hanging up his receiver, will light the supervisory lamp in the local side of the toll cord circuit. The toll operator will then take down the connection.

The act on the part of the toll operator of withdrawing the local plug from the toll trunk jack will light the clearing-out lamp associated with the toll trunk plug in the multiple jack at the local switchboard. The toll trunk operator will then take down the connection, and the calling subscriber's line will be free for another connection.

At the toll switching operator's postion at the multiple board it is customary to locate an order wire pilot lamp which lights whenever an incoming order wire call is received at that position, if a switching key at that position has been thrown. If there are in the exchange two or more toll trunk positions or toll trunk and incoming trunk positions, arrangement may be made so that incoming calls may be switched from one position to another in the same way that incoming calls are switched from one incoming trunk position to another.

The establishing of the final toll connection over a different portion of the multiple board than that at which the local subscriber's call originated, *i. e.*, through the multiple jack at the toll trunk position, rather than through the answering jack of the calling line, has an advantage not yet mentioned, in that it largely removes the possibility of fraud on the part of the calling subscriber. Owing to changes which may have been made at the intermediate distributing board, in the relation of the answering jack to the multiple jacks of any line; and owing to the existence of party lines where several subscribers are served by the same line, the operator who answers a call cannot tell whether a calling subscriber gives the proper number or not. The recording operator who receives this information directly from the calling subscriber has even less chance of knowing this. Under the arrangement described, where the original connection is taken down and the calling subscriber afterwards called through the multiple jack of the toll trunking position, any subscriber who attempted to get the toll connection charged to someone else would not get his connection at all, because the toll trunking operator would plug into the wrong multiple jack.

Calls from a toll line for a local connection ("toll to local") are handled in practically the same manner described above after the preliminary connection between the calling subscriber and the recording operator has been taken down and the ticket passed to the toll operator. In the toll to local connection the recording operator and the subscriber's operator play no part. The ticket is made out by the toll line operator who orders up the connection with the subscriber called for at the toll trunking position as before. Fig. 7 is therefore illustrative of a toll to local connection also.

KELLOGG TOLL SYSTEM B, USING NO RECORDING OPERATOR.

In small exchanges where the toll business does not justify having multiple toll boards, circuits known as two-way toll trunk circuits are provided. Each of these circuits ends at the multiple board in a plug and a lamp, and at the toll board in a cut-off jack and a lamp.

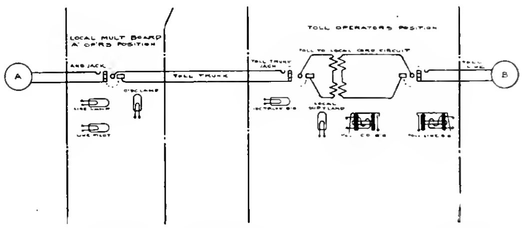

FIG. 8.—SHOWING CONNECTION BETWEEN LOCAL AND TOLL SUBSCRIBER IN KELLOGG SYSTEM "B."

The number of these circuits provided depends, of course, upon the amount of business which they will have to handle, but it is customary in many cases to provide two circuits at the right of every other operator's position. In this case each toll operator acts as a recording operator, and after receiving a call from the multiple board for a toll connection, puts up the connection herself, without the help of another operator. In describing this system reference is made to Fig. 8.

In this system the method of operation when a local subscriber calls for a toll connection, is as follows: The local subscriber signals his operator in the ordinary way and the operator inserts the answering plug of one of her cord circuits into the answering jack and finds out that connection with a toll line is desired. She then withdraws the answering plug from the answering jack and in its place inserts the plug of a two-way trunk line. This act will light the lamp associated with the toll board end of this trunk line. The toll operator will then insert the local side of one of her toll to local cord circuits into the jack of this trunk line and find out from the local subscriber the number of the toll line with which he desires to be connected. She will then insert the toll side of the cord circuit into the jack of this toll line and ring. She will find out by listening in at short intervals when the toll subscriber answers.

At the end of conversation the toll subscriber, or the distant toll operator, will throw down the clearing-out drop, and the local subscriber, by hanging up his receiver, will light the supervisory lamp in the local side of the toll to local cord circuit. When used for a local to toll connection this supervisory lamp does not light until conversation is finished. When the toll operator withdraws the local plug from the two-way trunk jack, the clearing-out lamp associated with the local board end of this trunk will light, and the subscriber's operator will take down the connection at the local board.

In the case of a call from a toll subscriber for a local subscriber, the toll subscriber will throw down the line drop at the toll board and the toll operator will plug in with the toll plug of a pair of toll to local cords, throw the listening key and find out that connection is desired with a local subscriber. She will then speak over an order wire to one of the operators at the multiple board, who has within her reach one or more of the plugs of the two-way toll trunk lines. The operator at the multiple board will designate the trunk line which is to be used and, without testing, insert the plug of this trunk into the multiple jack of the desired line and at the same time the toll operator will insert the local plug into the jack of this same trunk. The supervisory lamp in the local side of the cord circuit at the toll board will light, if the local subscriber's line is not busy, and the toll operator will ring. Thus the supervisory lamp in a toll to local cord circuit serves as a ringing signal in the same manner as described in connection with the toll system when recording operators are employed. When the local subscriber answers in response to the ringing of the operator, this lamp will be extinguished. At the end of conversation the toll operator will receive the disconnect signal from both the local subscriber and the toll subscriber, and will remove the toll and local plugs from the toll and trunk jacks, respectively. The act of removing the local plug from the latter will light the clearing-out lamp at the multiple board and the local operator will take down the connection.

In case the toll and local operators misundertand each other, and the toll operator plugs into a trunk line jack, other than the one assigned, the supervisory lamp in the local side of the cord circuit in use will not light, and the clearing-out lamp associated with the trunk plug which the local operator has inserted at the multiple jack, will light. In this way these lamps serve as guards against inaccurate connections.

In this system many of the refinements of the more complete Kellogg System A are lacking, but in many towns where the toll business is comparatively small, and the matter of first cost considerable, it has been found expedient to adopt it. In small exchanges the work does not warrant the expense of a toll trunk operator, and it is seen in this latter system, the work of the toll trunk operator is distributed among the subscriber's operators, while the work of the recording operator is distributed among the toll operators. Thus the principle of having the subscriber's operator do no work of a special nature, is sacrificed to expediency. The feature of preventing fraud on the part of a calling local subscriber is also sacrificed, but in small exchanges this feature is not as important as in large ones.

Recent Electrochemical Developments.

MERCURY CATHODE PROCESS FOR THE ELECTROLYSIS OF SODIUM CHLORIDE.

In a patent granted on January 5 to Mr. J. J. Rink, of Elsinore, Denmark, an apparatus for the electrolysis of sodium chloride is described in which a horizontal layer of mercury is continually moved through a series of cells in which the mercury is alternately alloyed with sodium and again decomposed. The first, third, etc., cells are, therefore, electrolytic cells in which by cathodic reaction sodium amalgam is produced, while the second, fourth, etc., cells serve for liberating the sodium from the amalgam and forming sodium hydroxide. The main new feature of the arrangement appears to be that the inventor makes the area of surface of mercury twice as great in the cells in which the mercury gives off its sodium, than in the electrolytic cells in which it is charged with the sodium. The electrolytic cells are made narrow in the direction of the movement of the mercury in order to keep the degree of amalgamation of the mercury low, while the large surface exposed to the lye in the other chambers enables the mercury to give off the sodium fully to the solution, so that pure mercury is introduced into the next electrolytic cell.

ELECTROLYTIC PRODUCTION OF HYDROXIDES AND OXIDES.

A patent granted to Mr. F. F. Hunt, of New Brighton, N. Y., describes the following method of electrolytically producing hydroxides or oxides of metals: Both electrodes of the electrolytic cell are made of the metal, the hydroxide or oxide of which is to be produced. If, for instance, tin hydroxide is wanted, both electrodes are of tin and a solution of sodium chloride is used as electrolyte. The current produces tin chloride at the anode and sodium hydroxide and hydrogen at the cathode; the tin chloride and sodium hydroxide then react with each other, with a resulting formation of sodium chloride and tin hydroxide. During the process water is lost, but the sodium chloride is continually regenerated, while tin hydroxide is produced. After a while polarization at the cathode would set in and would diminish the economy of the process. The inventor, therefore, reverses at suitable intervals (for instance, every minute) the direction of the current through the cell, thus making each electrode alternately anode and cathode. This appears to be the chief feature of his method. If the electrodes are made of a metal which does not form a hydroxide, like silver, the oxide instead of the hydroxide is formed.

STORAGE BATTERY INVENTION.

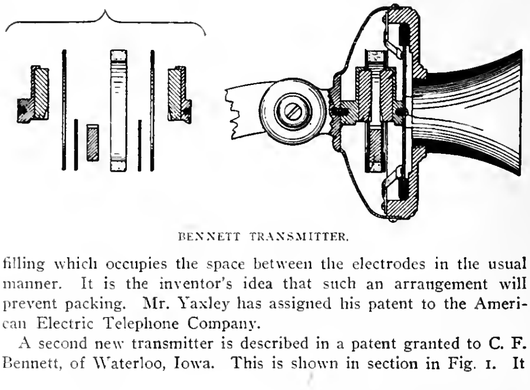
A patent granted to Mr. F. A. Feldkamp, of Newark, N. J., refers to a method of formation of accumulator plates by the following chemical process: Against a sheet of lead there are placed one or more pieces of suitable porous material, such as linen, cotton, cheese-cloth or other loosely-woven fabric in sufficient layers to obtain the desired thickness. For fastening these layers of porous material to the lead conductor, a method of sewing is used covered by a previous patent of the inventor. Upon the porous material is then sprinkled zinc dust or granular zinc and the plate is then suspended in a solution of lead acetate or lead nitrate with the result that lead separates from the solution and becomes thoroughly imbedded in the porous material in the form of spongy lead. The porous material or fabric may first be treated to render it acid proof.

New Telephone Patents.

NEW GRANULAR TRANSMITTER.

Since the scientific investigation of the so-called microphonic distance of various conducting substances some years ago, by which investigation it was proved conclusively that a maximum microphonic effect existed in a carbon contact, almost all transmitters have been designed using carbon electrodes. Here and there we find a departure from the general rule, some metal being used for one or both of the electrodes.

Last week's patent issue describes such a transmitter, in this case but one electrode—the stationary one—being of metal. This transmitter is the invention of E. E. Yaxley, of Chicago. The front electrode is a mass of carbon granules securely cemented to the diaphragm; while the rear one is of brass, cup-shaped, the bottom being corrugated. Over the mouth of this cup there is secured a perforated brass plate through which may freely pass the granular carbon



BENNETT TRANSMITTER.

filling which occupies the space between the electrodes in the usual manner. It is the inventor's idea that such an arrangement will prevent packing. Mr. Yaxley has assigned his patent to the American Electric Telephone Company.

A second new transmitter is described in a patent granted to C. F. Bennett, of Waterloo, Iowa. This is shown in section in Fig. 1. It will be at once noted that the movable electrodes comprise the upper portion of the walls of the button. The lower portion of the button is a carbon block with its upper surface practically horizontal. This forms a base upon which is mounted mica sectors and rings, which form a packing through which the semi-circular electrodes may freely vibrate to compress the carbon granules. A serrated upper surface to the stationary carbon block assists in agitating the granules.

PARTY LINE SYSTEM.

N. E. Norstrom, of Chicago, has patented a party line system embracing both subscribers' and central office mechanisms for selective and lock-out working. Unfortunately, the method of selection depends upon step-by-step switches, these being located at the subscribers' stations. This introduces such complication at the subscribers' stations that the system appears a retrograde step from the best modern systems.

Telephone Transmitters.—V.

By Arthur V. Abbott, C. E.

ERICSSON Transmitter.—The Ericsson Telephone Co. presents a transmitter which is somewhat unique in design and differs decidedly from most of those of American manufacture. In Fig. 35 a combined transmitter and receiver is shown, and also a model of the transmitter by itself. In Fig. 36 the transmitter of the combined model is shown dissected. In Fig. 37 the individual transmitter is opened, while in Fig. 38 it is completely dissected. In many respects the Ericsson transmitter resembles that manufactured by the Stromberg-Carlson Company.

The transmitter consists of a case of two parts ½ in. thick and 2¼ in. in diameter, made of pressed brass. The front half carries the diaphragm, as is shown in Fig. 37. This is of iron 2⅛ in. in

FIG. 35.—ERICSSON COMBINED TRANSMITTER AND RECEIVER.

diameter and .012 in. thick. The front electrode consists of a piece of brass in which a number of corrugations are punched, as is shown in Figs. 37 and 38. This front electrode may or may not be gold-plated, and is secured to the front of the diaphragm by means of a screw and carried to one side of the case and then attached underneath one of the springs, which check diaphragm vibrations. The capsule containing the carbon is curious. It consists in the first

FIG. 36.—ERICSSON INSTRUMENT DISSECTED.

place of a pressed brass cup, as shown in Fig. 38. This is lined with a celluloid washer, upon which a spider-shaped copper spring is placed. On top of the copper spring a carbon electrode is secured

FIG. 37.—ERICSSON TRANSMITTER PARTS.

and then around this electrode a felt ring 5/16 in. thick and 1¼ in. in diameter is placed. In the center of the electrode a little bit of felt is placed, as shown in Fig. 36. The interior of the felt ring is filled with 12 grains of coarse granular carbon. The carbon electrode is 7/16 in. in diameter, and contains three circular grooves. The diaphragm is protected by means of two heavy layers of oil silk and is cushioned by two rings of blotting paper.

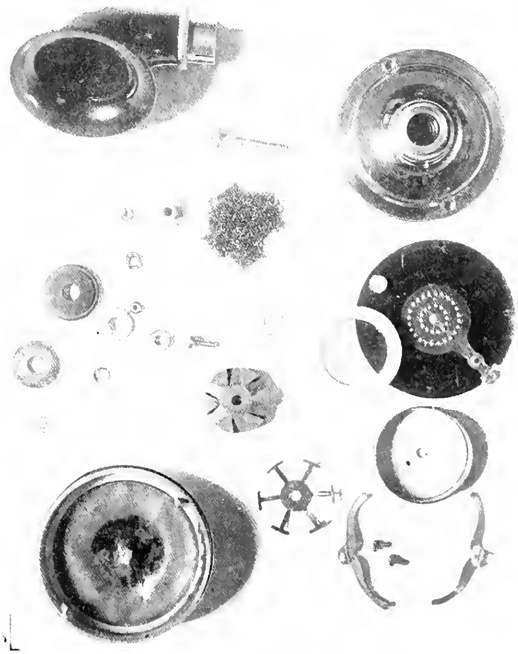


FIG. 38.—ERICSSON TRANSMITTER DISSECTED.

The Manhattan Transmitter.—The transmitter manufactured by the Manhattan Telephone Company is shown at *D*, Fig. 21. In Fig. 39 the rear cover is removed and in Fig. 40 the instrument is dissected. There is a light brass face plate fashioned in the usual manner, which contains a rough aluminum diaphragm 2⅜ in. in

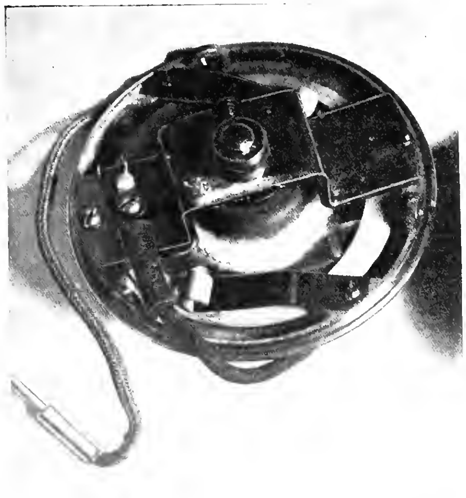

FIG. 39.—MANHATTAN TRANSMITTER WITH REAR COVER REMOVED.

diameter and .021 in. thick. On this diaphragm a heavy piece of flannel is cemented, and in the center of the flannel is placed a carbon electrode ½ in. in diameter. The rear electrode is designed to combine both the functions of an electrode and of a capsule for retaining the granular carbon. It consists of a round carbon block, having a deep cavity and a sharp edge, as shown in Fig. 40. This carbon block is ⅛ in. more in diameter than the front electrode and

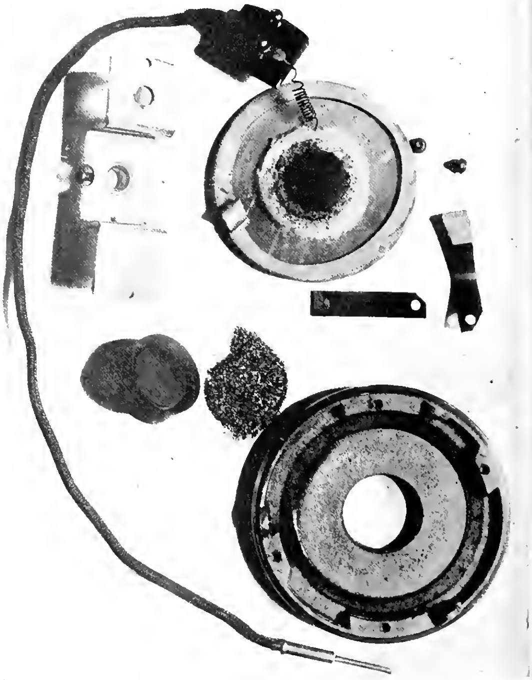

FIG. 40.—MANHATTAN TRANSMITTER DISSECTED.

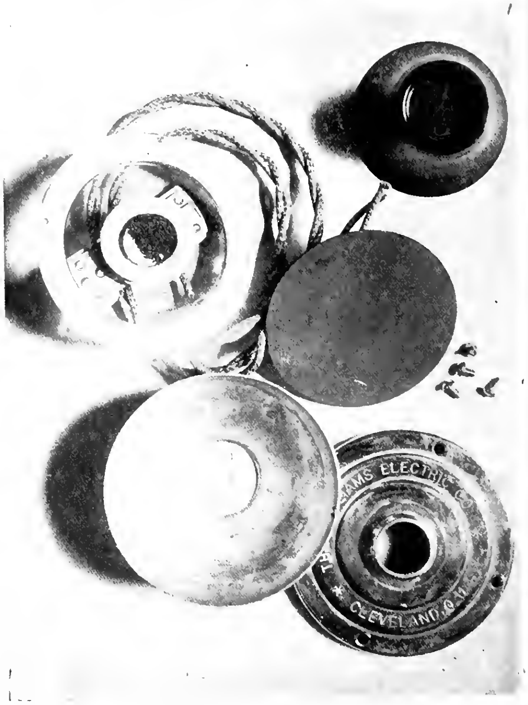

FIG. 41.—WILLIAMS TRANSMITTER DISSECTED.

is filled with 8 grains of granular carbon; then the diaphragm is placed over it so that the flannel covers the sharp edge of the cup.

The bridge, ⅞ in. wide and 1/16 in. thick, is then placed over a stud to which the carbon cup is attached and the whole placed upon the face plate, the bridge being secured by two screws.

This design relies upon the elasticity of the felt to seal the circumference of the carbon cup and to retain the granular carbon in position. A general construction of the instrument prior to the removal of the bridge may be readily seen from Fig. 39.

The Williams Transmitter.—This instrument is shown in Fig. 21 at *G* and in Figs. 41 and 42 dissected. The general shape of this transmitter is similar to all of the solid backs which use a hemispherical cap, but in this case both the front and rear of the instrument are of brass .03 in. in thickness. The diaphragm is of carbon

FIG. 42.—WILLIAMS TRANSMITTER DISSECTED.

2½ in. in diameter and .038 of an in. thick. It is placed directly upon the front half of the case without any cushion. The front of the carbon is covered with a heavy layer of varnish, presumably to make the carbon moisture-proof. The bridge consists of two parts, as shown in Fig. 42, a circular ring stamped out of brass, and a cross bar which is attached thereto by means of four insulated screws and rubber washers. This cross piece carries a spring, as is shown in Fig. 42, .018 of an in. thick and 2 in. long. The rear electrode consists of a disc of brass 1⅛ in. in diameter and .022 in. thick. This plate is dished in the center and provided with a small spool-shaped projection having a sharp point. This projection engages with the spring on the bridge, and the point centers in an adjusting screw that runs through the middle of the bridge plate. On the face of this electrode a ring of felt 1⅛ in. in diameter over all, ⅛ in. thick, with a ¾-in. hole, is cemented. This is filled with 8 grains of granular carbon and pressed directly upon the rear of the carbon diaphragm. It is evidently the office of the spring upon the bridge to keep the rear electrode and its ring of felt pressed tightly against the carbon diaphragm, while the adjusting screw is supposed to secure the necessary solidity by impinging upon the sharp tip which projects from the rear of the brass plate.

To the Front.

It is stated that the Japanese Government has ordered back to Japan twelve of the fifteen Japanese engineers who are at the Westinghouse Electric Company's plant at East Pittsburg, on account of the threatened war.

Meeting of the Chicago Electrical Association.

The evening of January 8 a large number of visitors and members of the Chicago Electrical Association listened to a very interesting lecture by Mr. C. G. Y. King, mechanical engineer of the Chicago Edison Company, on the erection of the 5,000-kw turbo-generators in the Fisk Street Station. A large number of lantern slides served to illustrate the successive steps taken in the work of preparing the foundations for and the erection of the units proper. This also afforded those present an opportunity to study the design and actual construction of a turbo-generator. The plan and cross-section of the power house was also shown and the lay-out of the same likened by Mr. King to a comb, the turbine room or row of turbines corresponding to the back of a comb and the batteries of the boilers to the teeth of the comb arranged at right angles to the turbine room.

The subject of an affiliation of the Chicago Electrical Association with the Western Society of Engineers was brought to the attention of the members by a resolution which was passed requesting the secretary to bring the matter to the attention of each member to permit of action being taken at the next meeting. Under such an arrangement the association would retain its integrity, being known as the Electrical Section of the Western Society of Engineers, and furthermore would enjoy all of the privileges which the members of the latter have. The election of officers resulted as follows: President, W. B. Hale; vice-president, F. M. Holbrook; secretary, De Witt C. Tanner; treasurer, H. G. Dimick; auditor, Hayward Cochrane; directors, Albert Scheible, Harold Almert and W. G. Carlton.

Electrical Equipment of a Modern Newspaper Office.

The invasion of the printing office by electricity has been well exemplified in our extended article on the Government Printing Office at Washington. The *New York Times* now gives some details of the electrical equipment for its superb new home on Broadway and Forty-second Street, showing that private enterprise is in no respect falling behind the standard set by a department with virtually unlimited national resources behind it. First of all it is interesting to note that the journal will not put in its own steam plant, as first intended, but will take service from the New York Edison Company. In so doing it gives publicly a number of pertinent reasons for its decision.

The following is the remarkable list of the uses and applications of electricity in the building, requiring, it is said, about 400,000 kw-hours per annum, or, say, 1,000 kw-hours daily:

One hundred and eleven motors—4 Hoe octuple presses; 1 press, job; 1 press, electric proof; 8 Kohler safety devices for controlling press movements; 2 autoplates, turning out eight stereo plates per minute; 38 linotypes; 3 pumps, house; 3 pumps, sewage; 1 pump, air compression for pneumatic tubes; 1 pump, air vacuum for cleaning carpets and offices; 1 pump, ink; 1 paper conveyor, for carrying printed papers from presses to delivery room; 7 elevators, passenger and lift; 4 Leonard system of control for elevators; 1 gallery lift; 8 trolley hoists for paper rolls; 8 fans for metal pots and for ventilating press room; 6 gymnasium; 1 machine shop lathe; 1 machine shop lathe; 1 stereo molding machine; 1 stereo tail cutter, round; 1 stereo shaver, round; 1 stereo router; 1 stereo shaver, flat; 1 stereo trimmer, flat; 1 stereo saw; 1 stereo jig and drill machine; 3 refrigeration.

Light—4,000 incandescent, 15 arc, Cooper Hewitt lamps, search, signs, bulletin service, elevator flash, cigar lighters, carriage call.

Heat—Stereo matrix; restaurant, including plate warmers, coffee urns, tea kettles, egg boilers, griddles, self-dumping oyster cooker for stews, toasters; stereo pastepot; soldering irons; hair curler for ladies' toilet; heating pads; heating tailors' irons.

Dental—Mallet, gold annealer, sterilizer, dental engine, mouth lamp, porcelain baking furnace, reflector for working on dark days, X-ray apparatus, cautery.

Miscellaneous—Time clock connection, fire alarm connection, telegraph connection, telephone connection, messenger call connection, office call connection.

The plaza north of *The Times* Building extends for a distance of 1,000 feet to Forty-sixth Street. The suggestion has been made for the erection of an immense electric flash sign above the sixteenth floor which shall give carriage calls for the seventeen theatres in that vicinity to carriages waiting in this large area. For instance, the number 623M would be a call from the Metropolitan Opera House; 542E would summon a carriage to the Empire; 427B would mean the Belasco Theatre, and 818N would give notive from the New Amsterdam. In this way carriages for all theatres would have an ample space, the plaza would become the real centre of midnight activity, and would reduce the inconvenience now caused by blocks and delays such as occur on opera nights.

CURRENT NEWS AND NOTES.

TELEPHONE FIGHT AHEAD.—It is reported that the Central Union Telephone Company, whose headquarters have just been moved from Chicago to Indianapolis, is to be used to fight the independent telephone companies in the Middle West, and if possible, prevent them from getting into Chicago. This promises to be an expensive campaign.

INDIANA ENGINEERING SOCIETY.—The fifth annual convention of the Indiana Engineering Society will be held in Indianapolis on January 14, 15 and 16. Papers will be read on the following named subjects: "Railway Construction," "Central Power and Heating Plants," "Surveys for Electric Railways," "Interurban Railways in Small Cities," "Statistical Paper on Interurban Roads." C. C. Brown is secretary of the society.

AUTOMOBILE SHOW.—The annual automobile show in New York City will begin on January 16 at Madison Square Garden and last one week. More than 185 firms have been accommodated in the distribution of space, and thirty or forty have had to go unprovided. The exhibition is held under the auspices of the Automobile Club of America, the National Association of Automobile Manufacturers and the Madison Square Garden Company, with Frank W. Sanger as manager.

THIRD RAIL IN PENNSYLVANIA.—It is said in a special dispatch from Wilkesbarre, Pa.: "Estimates are being made of the cost of equipping the Delaware & Hudson Railroad between this city and Carbondale with the third-rail system, to be used exclusively for passenger service. This is to compete with the Westinghouse Company's new cannon-ball third-rail system between this city and Scranton, and to relieve the congestion of freight and coal traffic which now crowd the road. The plan is to build a third-rail track alongside the present tracks, the roadbed being wide enough, and to use the present tracks for freight and coal." Why "cannon-ball"?

NEW YORK-PHILADELPHIA TROLLEY.—It is stated that by the Trenton Terminal Railway Company effecting an agreement with Joseph H. Mayer for the use of the land needed to join the tracks of the Camden and Trenton & Trenton and Trenton & New Brunswick trolley lines, the way was opened last week for continuous traction route between New York and Philadelphia. It will take but three weeks, after the weather moderates, after which time cars can run through New York to Philadelphia. This $1,500 purchase is all that has kept through service back for six months, it is said.

MUNICIPAL TELEPHONY.—In an interesting editorial note the New York *Tribune* says: "Municipal telephony is one of the enterprises into which the city of Glasgow went two or three years ago. How far it is judicious for local governments to perform functions ordinarily exercised by business corporations is a question about which there is a wide difference of opinion. Perhaps no universal rule can be laid down for all countries. In some of her other undertakings Glasgow has apparently been successful. In this one she has been peculiarly unfortunate. The cost of her plant exceeded the original estimates by about 50 per cent., and experts declared in advance that the low rate she offered to patrons would involve a loss. The municipal authorities keep a stiff upper lip in the present dilemma, but they doubtless feel that their course was ill advised."

NATIONAL ELECTRIC LIGHT ASSOCIATION.—One of the most interesting and valuable portions of the volume of *Transactions* which the National Electric Light Association is about to issue is the report with cuts in colors on Decorative and Sign Lighting. If for nothing else the members are likely to prize this volume on receiving it. Mr. Arthur Williams, the reporter on the subject, has been appointed to take up the matter again this year in a second report, and proposes to handle the subject in a somewhat different manner, adding to illustrations the ideas and opinions of central station men on advertising signs, and selecting instances in which decorative lighting of that character has been productive of increased trade and revenue to the users. He is now collecting such data, and all of our readers interested in the subject should communicate with him at the offices of the New York Edison Company.

ELECTRICITY IN INDIA.—A letter from United States Consul William Thostee, of Bombay, India, dated December 8, 1903, says: "As you are probably aware, Bombay is not lighted nor fanned by electric power. The cars are still horse trams, and what little electric lighting there is is in a private capacity. The tram lines, however, are to be turned into electric lines, and the contract has been let to the Brush Electrical Company, in England, who are expected to have things going by this time next year. The Bombay Electric Company, Meadows Street, Bombay, is the largest firm dealing in electric supplies and sundries. The Bombay Telephone Company, Limited, is the only telephone company in the city. The new Taj Mahal Hotel, which is just opened here, is to be fitted with electric fans and lights. It will have its own private installation and power house until the Brush Company get their installation in, and then will take its power from them."

ELECTRICITY IN SURGERY.—A special cable dispatch of January 9 to the New York *Sun* says: "The story of a curious surgical operation at the St. Antoine Hospital has been communicated to the Surgical Society. The patient swallowed a packing nail, which was shown by an X-ray photograph to have lodged, head downward, at the level of the seventh rib. A bronchoscope, which consists of a tube, the inner surface of which is highly polished to serve as a reflector, with an electric lamp arranged so as to throw a strong light on the tube, was passed into the bronchial tube and then withdrawn. This process was repeated for six days with larger and larger tubes, and then an eight millimeter tube was inserted to a depth of nearly fifteen inches. A magnet had been specially made to put into the tube, but it was too short to fit and the coughing of the patient forced a suspension of the operation. A second X-ray photograph showed that the nail had now slipped to the level of the eighth rib. The doctors, therefore, performed the operation of temporary tracheotomy. A ten millimeter tube was introduced to a depth of fourteen inches, and the operator then saw the nail. The magnet was introduced and the nail adhered to it. The whole operation lasted only five minutes and saved the patient's life."

GRADE CROSSINGS.—In his message to the Legislature of New York State, Governor Odell says: "The approval of an item in the last appropriation bill for the change of grade crossings in the city of Schenectady brings up an important question for consideration by the Legislature. As is well known, heretofore almost all of these improvements, so far as the State has been concerned, have been restricted to the rural communities. The State has declined to aid in the construction of roadways within the boundaries of the cities. But it is the State's duty to protect the lives of its citizens, whether in the cities or rural communities. Under existing laws the State contributes 25 per cent., the locality 25 per cent. and the railroads 50 per cent. for removing crossings at grade. There have been, however, no appropriations for any single piece of work such as that approved by me for the removal of crossings at grade in the city of Schenectady. If the policy of the State is to continue along this line it would be well to define some maximum limit to which it should go, and the whole work thereafter should be under the control of the Railroad Commission, appropriations being made in accordance with their recommendations. It would be well also to prohibit by statute any future grade crossings in the State in the construction of railroads so that this expense may be guarded against in the future. It will certainly grow to alarming proportions otherwise, unless the localities, have their interests in this direction sufficiently protected." The trolley car traffic at this point is very large.

RADIUM IN UTAH.—It is claimed that two discoveries of ore that contains radium have been made in Utah and Idaho by Capt. James Lawrence, a geologist and mining expert. Lawrence says that the strike is a most important one, and will have the effect of reducing the present price. The ore has been tested by a New York assayer, and is said to have a large amount of the precious radium in it.

A WEIRD WIRE WALL.—At Washington on January 5 Representative Dixon introduced a resolution directing the Secretary of Commerce and Labor to inquire into the cost and feasibility of constructing a wire fence along the Canadian boundary between Lake of the Woods and Point Roberts. The purpose of the wire fence, as disclosed in the preamble of the resolution, is to keep out Chinese laborers who steal across the line and to prevent violation of the law with respect to smuggling. Mr. Dixon wants the fence equipped with telegraph, telephone or other electric apparatus to convey warning to inspectors and others charged with the execution of the exclusion and tariff laws.

RADIUM AND MINE SLAG.—A cable dispatch from London of January 5 says: "Prof. Ellershausen, a German, has invented a method of extracting zinc white from refuse slag. He and Prof. Sir William Ramsay successfully experimented at the Hafaa mine in North Wales to-day, showing that a ton of zinc white can be extracted from fifteen tons of slag by a far simpler and cheaper process than is now used in a roundabout production from spelter. Great Britain imports about 200,000 tons of zinc white annually from the United States, Germany and Belgium because its manufacture from spelter is unprofitable. It is now apparent that millions of tons of mine refuse that has hitherto been regarded as useless can be turned to account. Prof. Ramsay said, after the experiments, that he could not see why a new era of prosperity should not dawn in Wales. It is noteworthy that in the course of the process cadmium is extracted, which is serviceable in procuring radium."

THE WEATHER BUREAU.—"Only 17 per cent. of our weather forecasts throughout the year were inaccurate," said Prof. Willis Moore, chief of the Weather Bureau, in addressing the House Committee on Agriculture on January 9 on the annual appropriation bill. The members of the committee looked out and saw the sun shining brightly and then turned and read the professor's daily weather map, which said "partly cloudy," remembered his prediction of a rise in temperature when a cold wave came instead, smiled and said nothing. Prof. Moore added that until experience has led to new discoveries in meteorological science there would always be a certain percentage of inaccurate forecasts. He asked for an increase in the appropriations for the bureau to provide for the establishment of eight additional stations as follows: At Providence, R. I.; Hartford, Conn.; Honolulu, Sitka, Alaska; Roswell, N. M.; Durango, Colo.; Madison, Wis., and one in north central Illinois. He also asked for $50,000 for increase of buildings. The total amount desired for the Weather Bureau is $1,500,000.

FARM TELEPHONES are a familiar feature out West, but a correspondent of the New York *Evening Post* says about them in Connecticut: "The coming report of the telephone company, which, outside of the single town of Greenwich, practically monopolizes the Connecticut field, will show that the corporation has about 25,000 stations in the State, of which about 5,000 have been installed during the past year. Of the new stations about one-quarter, or some 1,250, are of a distinctively farm character—that is, established in farm houses or in outlying parts of farm towns. Nine of the forty-five exchanges of the corporation are now either in farm towns or are in towns where the farm business of the company is very large and where the wires reach over an extensive farm region. The company is pushing steadily and increasingly its rural extensions and making closer connections with the few independent farm telephone groups. Sometimes the company leases its instruments to the farmers, sometimes the farmers construct the lines and keep them in repair, and sometimes the company; but in practically all cases the farmers are connected either by toll line or regular service with the nearest exchange, and through it with the general system of the State. According to a high official of the company, about 6,000 stations in the State are now of a "farm" character; and the farmer, when once he takes the telephone at the regular rate of $18 a year, rarely drops it."

Letter to the Editors.

The Choice of Wattmeters.

To the Editors of Electrical World and Engineer:

Sirs:—It has been with much interest that I have read the article by Mr. MacGahan in the Electrical World and Engineer of November 21, 1903, under the heading of "The Choice of Wattmeters." Being deeply interested in the subject of electrical measuring instruments itself, and particularly in recording or integrating wattmeters, I beg to ask your indulgence in presenting a somewhat different view from that held by Mr. MacGahan.

There is no room for a difference of opinion relative to the primary requirement of a recording wattmeter—accuracy; not simply initial accuracy, for that is a comparatively easy requirement to fulfill, but continued accuracy after a long period of service. It is to this end that the meter manufacturer is striving and the rapid strides during the past few months in this direction are the result. Referring more specifically to the article under discussion, in connection with which I differ from Mr. MacGahan is the following:

"When it is stated that a wattmeter is accurate within 2 per cent. it is meant that all these cases (referring to variations of operating conditions) each of a magnitude such as would be found in actual operation and all acting in unison produce a resultant error not exceeding 2 per cent." For the sake of argument, we will ignore the fact that there must invariably be errors due to observation standards used in making tests, etc., which in themselves cannot be depended on under ordinary conditions within one-half of the above limits, and discuss only the errors inherent in the meters themselves.

A 10 per cent. change in voltage or frequency is not uncommon in actual central station practice, and it is well understood that a meter that will not vary more than 1 per cent. in accuracy under the above conditions has well nigh reached the acme of perfection. A combination of these two variations, provided they are concurrent, and such I understand is the way Mr. MacGahan has considered them, will produce the error of 2 per cent. Combined with these may also be errors due to the other causes mentioned. I do not wish in any sense to imply that these variations are always cumulative, for as a matter of fact they frequently act differentially and thus the combined error may be well within the limit cited. The point I wish to make is that conditions exist in service under which any meter may be in error in excess of 2 per cent. as a result of an accumulation of error influences. I would instantly test any meter which I found in service under such a guarantee and the results would, I think, leave no doubt as to the truth of the claim.

There is, of course, now, and always has been, a great difference of opinion relative to sealing of wattmeters by the manufacturer, but I must differ from Mr. MacGahan in his statement that "The only excuse for a manufacturer supplying unsealed wattmeters is in cases where their moving element is so heavy that the jewel bearings would not stand the rough handling due to shipment, etc."

The desirability of an unsealed meter from the central station's standpoint is completely ignored. Granted that a manufacturer cannot make time guarantees on unsealed meters, the main benefit accruing from the ability of the purchaser to make his own adjustments, repairs, etc., should not be lost sight of. In a large majority of cases the only repairs or recalibration necessary can be accomplished on a meter at the point of installation with the expenditure of a minimum amount of time and labor; but if the meter is sealed by the manufacturer there is nothing to do but remove and return often involving delay and dissatisfaction, not to mention the temporary loss of the meter itself.

I note further this statement: "It should be understood, of course, that the manufacturer's seal does not prevent the purchaser from repairing his own wattmeter if he so desires." Does not this itself refute what has been said earlier in the article regarding "dispute with customer" * * * "Seal and guarantee—by disinterested party" * * * "only excuse for a manufacturer supplying unsealed wattmeters, etc.?"

It has been my experience that whenever the manufacturer's seal is broken there his responsibility ends, and this being the case the effect of a manufacturer's seal actually prevents purchasers making their own repairs when otherwise they much prefer to do so. Is not the real reason for a manufacturer's sealing his meter explained by the conclusion that the mechanism is so delicate and difficult to adjust at the hands of the ordinary central station man that it can be entrusted only to the care of experts, or in other words to the manufacturer himself? Is it not a fact that the example of sealing was not by a meter which its makers claimed to be too delicate and too complicated for proper care by the average meter man, and is not the same tendency rather towards unsealed wattmeters with all makers simply because a delicate sealed meter is too unpopular to be universally introduced?

Passing now to the determining factor of a meter's life, I find that Mr. MacGahan has eliminated from consideration all friction causes except that due to the disc rotating on the jewel bearing. I admit that the friction due to the recording mechanism and top bearing is very small and difficult to measure, but I maintain that this friction is a very considerable portion of the total friction in the meter, and as it is constantly increasing due to age and use, therefore, is not negligible.

The ratio of torque to weight is not nor can it be a true measure of a meter's value. For example, by doubling the thickness of the disc the torque is doubled, likewise the weight, but is the total friction of the meter also increased twofold? Not by any means. The friction due to the top bearing is but slightly if any increased. So here, then, is a distinct advantage of increasing the torque even at the expense of increasing the weight in an equal degree. If it is possible to get an accurate measure of the friction torque, then the meter showing the highest ratio of full load torque to friction torque must in the natural order of things have the most enduring accuracy.

Furthermore, high torque in a meter has its greatest value in overcoming, not initial friction, but increase of friction. Here the weight of the moving element has no effect except upon the pivot and jewel friction, and if the highest grade only of eastern sapphires are used for the bearing, practically no jewel trouble is experienced, with any meter of the induction type at present on the American market. What else, therefore, remains to cause an increased friction, except the top bearing and recording mechanism which are obviously independent of the weight of the moving element?

I do not wish in the least to imply that the lightest moving element possible with a given torque is undesirable, nor that high torque should be attained solely by a heavy moving element; but I do maintain that ratio of torque to weight is not a reliable indication of the life of a meter. Tests which I have made, however, show that the highest torque induction meter on the market to-day has a greater ratio of torque to weight than any other jewel bearing meter.

CURRENT ELECTRICAL LITERATURE.

DYNAMOS, MOTORS AND TRANSFORMERS.

Measuring the Slip of Induction Motors.—BIANCHI.—An illustrated description of several methods for measuring the slip of induction motors. What he considers to be the simplest and most exact method which can be used when the induction motor has an armature connected to slip rings in connection with an outside rheostat, is to bring a magnet needle swinging between two arresting pins, $h\,h$ (Fig. 1) near the connecting wire between motor and rheostat,

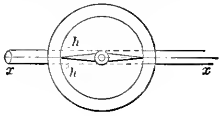

FIG. 1.

so that the axle of the needle is in the direction of the wire. If the frequency of the current in the wire is n (from which, of course, the slip of the motor can be easily determined, since n is the frequency corresponding to the slip), the magnet needle makes $60\,n$ periodic movements per minute, which may be counted. If the motor has a squirrel-cage armature this method can, of course, not be used. In this case he applies the arrangement shown in Fig. 2.

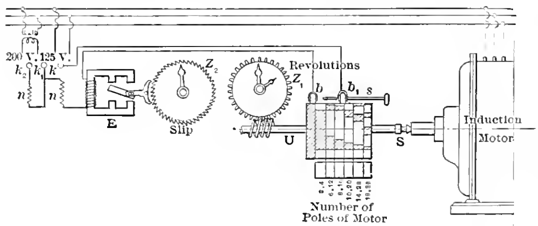

FIG. 2.

Connected to the shaft of the induction motor is the rod S, geared at its end to a disc, Z_1, by which the revolutions are counted. The same rod carries the commutator, U, consisting of a series of contact discs and two brushes, b and b_1. C_2 is the dial which counts the number of impulses sent from the commutator, U, to the electromagnet, E. There are three terminals, k, k_1 and k_2; k and k_1 are used for voltages between 70 and 125, while k and k_2 are used between 125 and 200 volts. In the case of a high-voltage motor a small auxiliary transformer is made use of. The commutator, U, serves for sending periodic currents to the electromagnet. U consists of seven contact discs, the first of which has an uninterrupted metallic surface on which the brush, b, slides. The other contact discs have different numbers of insulating pieces inserted on their surface, and the brush, b_1, is connected to that contact disc which corresponds to the number of poles of the motor. The electromagnet, E, has four free poles, between which a permanent magnet oscillates as armature and transmits these oscillations to Z_2. If the terminals, k and k_1 are connected with the network, while S is not yet set into the motor shaft, then there will be no oscillations of the armature of the magnet, E, although there may be a connection between b and b_1. The reason is that the frequency of the exciting current is too high and the inertia of the armature of the magnet is too great. If, however, S is set into the motor axle, then the frequency of the current supplied to E corresponds to the frequency of the rotor current, which is, of course, the frequency of the slip. To such a slow frequency the armature of the magnet, E, can follow. From the reading obtained on Z_1 and Z_2 the slip can be easily determined.—*Elek. Zeit.*, December 24.

POWER.

Electric Power with Greatly Varying Load.—LIOUVILLE.—A mathematical article discussing the case where power is supplied to a number of intermittently working machines, so that the power required from the generator is constantly varying. If for the generator an armature be used capable of carrying continually the maximum intensity of current, one would arrive at too large dimensions. On the other hand, it is incorrect to base the dimensions on the mean current, since this gives in general too small dimensions. The armature is to be considered as the seat of an irregularly pulsating current, the heat effect of which is proportional to the mean square of the instantaneous values of the current. He gives some mathematical calculations which show that if n equal motors are to be supplied with current, the heat effect is n times the square of the effective current, $+\ n$ times $n - 1$ times the square of the mean current. For instance, in the case of three motors, each taking 50 amp. for 20 seconds, 10 amp. for 10 seconds, and no current for 30 seconds, the heat effect corresponds to an effective current of 67.5 amp.; while if simply the mean intensity had been taken, a current of only 55 amp. would have been found, thus involving an appreciable error. —*L'Ind. Elec.*, November 25.

TRACTION.

Alternating-Current Traction.—EBORALL.—The conclusion of his illustrated paper. He discusses at length the tandem-parallel control, which, if compared with the rheostatic control, offers considerable advantages from the point of view of rapid acceleration and economy. Quite apart from the considerably diminished losses in the rheostats, an appreciable amount of energy can be returned to the lines during retardation. However, both the efficiency and power factor when running in tandem are considerably worse than the corresponding values when the motors are working in parallel, and at light loads this disadvantage is rather great. These disadvantages are inherent in the method and independent of the manner in which it is carried out; they become very serious at usual frequencies, so that it is quite doubtful whether tandem-parallel control is commercially practicable at frequencies much above 25. The commercial application of tandem-parallel control in any form to multiple-unit trains would be difficult, if not impossible. It is, of course, perfectly possible with rheostatic control of the motors. He then discusses the various motors which have been recently proposed for single-phase traction: Series motors (Lamme, Finzi); repulsion-induction motors (E. Arnold, Deri, Schuler); repulsion-series motors (Latour, Eichberg-Winter). The scheme of the latter is very clearly and briefly indicated in Fig. 3, *a* and *b*. He thinks that both arrangements are quite similar, and that the only difference

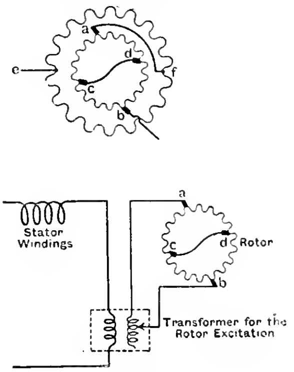

FIG. 3.

between them, apart from constructional details, is that in the Winter-Eichberg motor the rotor is indirectly in series with the stator, as indicated in Fig. 3, *b*. The use of the current transformer for supplying the brushes, *a b*, allows the stator to be worked at the full line pressure, no step-down transformer being, therefore, required on the car. At the same time the entire switching and the speed control is performed on the low-pressure side, i. e., in the secondary circuit of the current transformer. Naturally, the arrangement lends itself well to multiple-unit trains, the control being characterized by the absence of rheostatic losses and by the permanent connection of the various motors in parallel.

Single-Phase and Three-Phase Traction.—NIETHAMMER.—A reply to Szasz, who had recently compared the Eichberg-Winter single-phase motor with the three-phase motor, with relation to their suitability for traction purposes, and had reached conclusions somewhat in favor of the latter, as recently noticed in the Digest. The present author says that he has never denied that the commutator single-phase motor lacks entirely bad properties, since it is 10 or 20 per cent., or even more heavier and larger than a direct-current motor, and, therefore, also somewhat heavier than a three-phase induction motor. Moreover, the commutator motor at rest has as large or larger iron losses than when running, being thus similar to the three-phase induction motor, and dissimilar to the direct-current motor. With repeated startings the commutator single-phase motor will heat more than the direct-current motor. The present author believes, however, that Szasz's comparison between the single-phase and a three-phase motor is unfair, since there are important differences in details of the construction of both motors—for instance, with regard to the air-gap. He finally points out that the compensated single-phase commutator motor has the undeniable advantage that it needs one less conductor than the three-phase motor; that economical starting is possible without losses in resistances; that it changes speed like the direct-current series motor, in accordance with the load; and that it allows an economical regulation of speed. A disadvantage, however, is that single-phase conductors, generators and transformers are 10 to 30 per cent. more expensive than polyphase apparatus, and this disadvantage cannot be completely overcome by generating polyphase currents and supplying the currents of the different phases to different sections of the road.—*Zeit. f. Elek.* (Vienna), November 29.

SZASZ.—A reply to Niethammer's criticism. He does not think that the difference of the details of construction renders his comparison unfair, since he has compared the representative types of the two motors in their completeness without taking into account differences in detail. Concerning the possibility of maintaining a schedule of three-phase traction, he says that the tandem connection of the motors enables one to maintain any schedule which has been designed for an average speed between full and half speed corresponding to the parallel or the tandem connection of the motors respectively.—*Zeit. f. Elek.* (Vienna), December 20.

Electrical Heating of Third Rails for Sleet Removal.—A description of a method of removing the sleet from the third rail by heating it up by electrical means. Calculations are submitted as to the amount of power required, and it is estimated that 20 kw will raise the temperature of 1,000 ft. of a rail of the size used in New York, within a reasonable time, from 8 to 10° F., and that one-tenth of this power only will then be required to maintain the rail at this temperature. It is proposed to use transformers every 500 ft., and as these are used only two or three days during the year they can be cheaply built and can be manufactured for about $5 per kilowatt. Their operation will not interfere with the use of the rail for train service, as the rail need not be sectionalized. With the alternating current, the outside of the rail will heat up first and this is a desirable feature.—*St. R'y Jour.*, December 12.

Mountain Railway.—WILSON.—A fully-illustrated description of the Chamonix Railway in Switzerland, which has a length of 12 miles and several steep grades, the heaviest being 9 per cent. and 8 per cent. over 2,300 and 1,500 yards, respectively, while inclines of 2 per cent. are frequent. Two water power stations supply the energy, each being equipped with four 350-hp turbines, the generating voltage being 550 volts. A third rail is used, placed on one side or the other of the line, according to necessity, and with its crown 9 in. above the top of the running rails. It is fixed with iron bolts to insulating blocks of paraffined beech, which, in turn, are bolted to oak distance pieces fixed on the ends of the sleepers. The maximum leakage to earth is stated to be less than one ampere per thousand yards. The fact that this decreases with the fall of rain or snow is explained by the assumption that any dust which has accumulated on the surface of the insulating blocks and caused leakage, is washed away by the action of the rain. To allow of the passage of cars at grade crossings and switches, a gap is left in the contact rail, the interval being bridged by a copper bond laid underground in a wooden trough, run up solid with asphalt. At all such interruptions the rails are so disposed that at no time are the collector shoes on the cars entirely out of contact with the third rail. In the stations and wherever the public may have access to the lines, the third rail is protected by a guard plank. All cars are equipped with motors, each truck having two axles, each of which is driven independently by an electric motor. Each truck is provided with four collector shoes, two on each side. The shoes are supported on a system of hinge joints and are pressed downwards by springs, so that they follow any inequality in the height of the rail and always make good contact. Each car has a controller and all the controllers on the train are worked simultaneously by compressed air.—*Cassier's Mag.*, January.

REFERENCES.

Single-Phase Motor.—EICHBERG.—A communication in which he and Winter protest against Latour's priority claim recently noticed in the Digest. Their common work has been carried on absolutely independently of Latour and only shows similarity with the latter's motors in one point, namely, in respect to the excitation through the armature. This method of exciting is contained in their German patent application of November 15, 1901, while Latour claims that it is shown in his French application of December 12, 1901. This method of exciting becomes especially valuable in connection with their system of speed regulation, "for only in connection with this system is it possible to run within a wide range of speed with a power factor of 0.95 to 1.0."—Lond. *Elec.*, December 25.

Heatingof Railway Motors.—GONZENBACH.—Some comments on an article of Dodd and Canfield on ventilation of railway motors. The writers consider that for high-speed interurban service the artificial ventilation of motors is highly desirable. It is scoffed at in some quarters, but the writer compares the ventilation of motors with the ventilation of transformers and concludes that the usual practice of blowing air through transformers should be used with direct-current motors or else some other methods of cooling motors should be employed.—*St. R'y Jour.*, December 12.

Efficiency of Transmission Systems.—An article giving the results of some tests on the efficiency of one of the distribution systems in the Middle West. The line is 100 miles in length and power is distributed at 26,000 volts from one station. The maximum distance to which power is transmitted is about 60 miles. The apparatus losses were 11.9 per cent. and the transmission losses were 5.1 per cent.—*St. R'y Jour.*, December 19.

Installations, Systems and Appliances.

Central Station Statistics of Germany.—Extended annual statistical tables giving information up to April 1, 1903; 939 stations are noticed, while no information was available concerning 32 stations, so that in reality the number of central stations in Germany is 971. Insulated plants are not included. There are now 50 plants which have a capacity above 2,000 kw. The highest capacity, namely, 26,523 kw, is that of the Moabit station of Berlin. The total capacity of these 50 stations, which are situated in 37 cities, is 271,479 kw. The total number of plants is 939 (against 870 in 1902), to which there are connected 5,050,584 (against 4,200,203 in 1902) incandescent lamps of 50 watts, 93,415 (against 84,891 in 1902) arc lamps of 10 amp., and motors of an aggregate capacity of 218,953 hp (against 192,059 hp in 1902). There are a number of stations which supply current, not to a single town, but to a number of towns. For instance, the Bruehl station supplies 66 towns, at a distance of 9 to 12 miles, with current for light and power. The whole industrial district of upper Silesia is supplied from a single plant, while the water power plant at the Rhine falls supplies 46 towns. These stations have a very favorable influence on the industrial development of a district. Some larger tramway companies intend to enlarge their tramway stations into stations for supplying light and power over greater districts. In the industrial districts near the Rhine, there are a number of smaller stations which supply current for power in houses and smaller shops. For instance, the station of Anrath, near Crefeld, supplies current to motors, each of not more than a quarter or a half horse-power, used for silk manufacture in houses. The statistical tables cover 28 pages. The following figures are taken from the summary of the 939 stations. There are 766 stations with 257,-243 kw, using direct current; 45 stations with 30,550 kw, using single or two-phase alternating current; 59 stations with 83,283 kw, using three-phase current; two stations of 970 kw with monocyclic systems, while 67 stations use a mixed system. Of the latter, 55 stations with 102,470 kw, use a combined three-phase and direct-current system, while 12 stations with 8,041 kw, use a combined single-phase and direct-current system. The 939 stations are situated in 906 cities; 552 stations with 316,235 kw use steam power, 98 stations with 24,-851 kw use water power, 61 stations with 6,378 kw have gas engines. In one station with 220 kw wind power is utilized; 196 stations with 41,861 kw use both hydraulic and steam power. Of the 939 stations, 339 have a total capacity up to 100 kw, 422 stations a total capacity between 101 and 500 kw, 90 between 501 and 1,000, 39 between 1,001 and 2,000, 30 between 2,001 and 5,000 kw, and 19 more than 5,000 kw. There are in use 203,758 electricity meters.—*Elek. Zeit.*, December 24.

Isolated Station.—A fully-illustrated description of the power, light and heat plant for a large establishment in Berlin. It was necessary to crowd a plant of 2,400 hp into a large shop building, wedged in on all sides between shops and private residences. The plant has been placed in the basement and under the roof, the area built upon being 70,000 sq. ft. The demand for power, light and heat varies very much, there being a total power demand of 1,020 hp for normal conditions with a maximum of 2,345 hp. These 230-hp and two 500 to 700-hp engines are in use, while a storage battery of 7,200 amp.-hours, which can be discharged at 2,052 amp., has been put down. A central injection-condensing plant was adopted for the whole engine outfit. There are installed 460 arc lamps, 13,000 incandescent lamps and 56 large Nernst lamps, while for the elevators, ventilators, refrigerating machinery, etc., 32 electric motors with an average total power consumption of 120 kw are installed. The equipment of the boiler and engine rooms is fully illustrated in diagrams. The article is to be concluded.—Lond. *Eng'ing*, December 18.

Switches.—Woodfin.—An article illustrated by diagrams and tables giving details of the design and manufacture of a double-pole switch.—Lond. *Elec. Rev.*, December 25.

Electro-Physics and Magnetism.

Radiation.—Sanford.—A long paper on an undescribed form of radiation. When the terminals of the secondary winding of an induction coil are connected to the plates of an air condenser, the condenser plate connected to the cathode gives off a peculiar form of radiation into the condenser field whenever the current is interrupted in the primary coil. If a spark is allowed to pass between the discharging knobs of the secondary, the radiation is given off from both condenser plates; but when no discharge occurs it is given off only from the cathode plate. This radiation appears to be of the same nature as the ultra-violet radiation from a luminous body, and may be reflected, refracted and polarized like ordinary light. When it falls upon bodies placed in the condenser field, these bodies become sources of a secondary radiation very similar in its properties to the primary radiation by which it is produced. This secondary radiation may, in the case of metals at least, be given off both from the side of the body upon which the primary radiation from the cathode falls and from the side facing the anode. It may even be given off into an insulated hollow conductor placed in the condenser field. In addition to this secondary radiation, the metals may reflect the original primary radiation. The experiments made by the author are described at length. To explain them he says that had the experiments been carried on in the field of a condenser from which the air had been exhausted, the ordinary cathode radiation would have passed across from the cathode plate to the anode. Since this cathode radiation is believed to consist of negatively-charged electrons driven off from the cathode, it seems probably that the same electrons will be sent off when the space between the condenser plates is filled with air. In the latter case they are stopped by colliding with air molecules, while in the former case they are stopped only by the anode or the walls of the containing vessel. These electrons when striking against the walls of the tube or against metal plate contained in the tube, give rise to the Röntgen radiation, and it seems probable that their collisions with the gas molecules in the condenser give rise to the radiation described by the author.—*Phys. Rev.*, December.

Secondary Radioactivity in the Electrolysis of Thorium Solutions.—Pegram.—It is well known that the surface of bodies in the air near thorium compounds becomes charged with a temporary radioactivity under the influence of the thorium emanation, and that its activity is much increased if the surface is negatively electrified. The present author investigated what results would be obtained by electrolysis of solutions containing salts of thorium. With platinum electrodes he found that the anode became more or less radioactive, and that this radioactivity was only temporary. From solutions of "chemically-pure" thorium nitrate he obtained a thin adherent anode deposit which was found to be highly radioactive, and when analyzed turned out to be lead peroxide. This proves, of course, the impurity of the thorium nitrate used. If is added a small amount of some salt such as lead nitrate or copper nitrate, to a solution of pure thorium nitrate, a metallic cathodic or oxide anodic deposit may be obtained which is found to be radioactive. From solutions of the purest thorium nitrate obtainable no visible deposit is obtained on the anode, yet it is radioactive, the activity in this case decaying rapidly, becoming nil in about half in one hour. To explain the phenomena two hypotheses may be made. First, that the molecules or the atoms of the lead peroxide have been so disturbed by being closely associated with the radioactive thorium that they now exhibit the properties of radioactive matter; or, second, the radioactivity is a property of some kind of matter derived from the thorium which in some way becomes closely attached to the lead peroxide. The second view of secondary radioactivity is strongly supported by most of the work relating to the question. In adopting it, there is still the question of how the radioactive matter comes to be so closely connected to the lead peroxide as to be precipitated with it; that is, whether the connection is an atomic, molecular, or simply a mechanical one.—*Phys. Rev.*, December.

Induction, Inductance and the Induction Coil.—An illustrated didactic article treating on these three subjects.—*Am. Elec.*, December.

Electro-Chemistry and Batteries.

Edison Storage Battery.—Janel.—An abstract of a paper read before the International Society of Electricians in Paris, giving some information on the manufacture of the active material. The active iron material, consisting of a mixture of iron and protoxide of iron, is obtained by passing a current of hydrogen over pulverized sesquioxide of iron at a certain temperature, given as 480° C. The reduced iron is then very slowly cooled in a current of hydrogen and washed in water; it thus loses its property of igniting, or at least of oxidizing, when exposed to air. The mixture is a bad conductor and conductivity was formerly imparted to it by the addition of graphite. It is stated that the use of graphite has now been abandoned for the active iron material, and a different process of manufacture is employed. The iron is not raised to quite so high a temperature, and, therefore, probably contains less protoxide; it is then mixed with ammoniated copper and oxide of mercury, and, the iron reducing the compounds, there is finally obtained a mixture containing 64 per cent. of iron, 30 per cent. of copper and 6 per cent. of mercury. Each particle of this mixture is said to be made up of a grain of iron covered by a porous envelope of copper amalgam, in a very finely divided state, together with a small quantity of oxide of iron. In the latest type of cell, the number of plates with an active nickel mass is twice as great as that of the plates with an active iron mass.—Lond. *Elec.*, December 25.

Color Photography and Electrolysis.—RIEDER.—An article in which he suggests that the fact that very beautiful colors can be obtained by anodic deposits might be utilized for a solution of the problem of photography in colors. He has made some preliminary experiments in this direction. He first produces a picture on a sensitive plate, the methods used by him being described in detail, and then brings the plate as anode into a bath for producing colors on the plate. He really thus gets a picture with several fine colors, but the colors do not agree with those in nature.—*Zeit. f. Elektrochemie*, November 19.

Anti-Friction Metal.—RIEDER.—An illustrated description of a method of making an anti-friction metal consisting of graphite grains embedded in copper. A layer of graphite grains is placed at the bottom of a mould and the copper is deposited electrolytically so as to fill the spaces between the grains. After these are filled, another layer of graphite grains is placed upon the first one and electrolysis is continued, etc. The best graphite grains for this purpose have the size and irregular forms of carborundum No. 30. If such a copper surface in which graphite grains are embedded rubs against another metallic surface, then the wear and tear causes some graphite to come between the two rubbing surfaces, so that the friction is diminished and the wear and tear is counteracted. It is possible to render the copper deposit more or less porous by varying the current density. He believes this material might be suitable for dynamo brushes.—*Elek. Anz.*, December 13.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Meters for Four-Wire, Three-Phase Systems.—STERN.—An illustrated article in which the author first refers to the fact that if the design of a three-phase meter is based on the most general equations of a three-phase system, it becomes very complicated. It is much easier to design meters for the practical conditions under which a four-wire, three-phase system is generally operated. The secondary network is mostly arranged in such a way that between the three mean conductors and the neutral wire there is a voltage suitable for lighting, say 110 volts, so that between any two main conductors the voltage is 190. The lamps, which are non-inductive, are connected between the neutral wire and a main wire, while the motors are connected to the main wires. In many cases another tariff is used for charging for light than for power, so that the problem of measuring the power is to be subdivided into two problems, the one relating to the determination of the power consumed by the motors, and the other to measuring the non-inductive load between any of the three

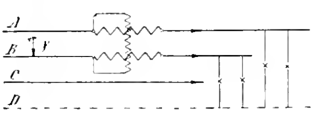

FIG. 4.

main conductors and the neutral wire. For measuring the power of the motors a three-phase motor for equally loaded phases may be used, especially if the neutral wire is not connected to the neutral point of the motor. For measuring the non-inductive load of the lamps, three cases must be distinguished, namely, whether, besides the neutral wire, one or two or three of the main conductors are brought into the building. If only one is in the building, an ordinary single-phase motor may be used. If two main conductors are brought into the building, the arrangement of Fig. 4 may be used in which the two currents, *A* and *B*, are combined to act in opposition, while this combination is made to act together with the voltage between *A* and *B*. This arrangement, which corresponds to an ordinary three-wire meter arrangement, measures the non-inductive load between *B* and *D* and between *A* and *D*. It is, however, supposed that there is no consumption of power between the conductors *A* and *B*. If all three main conductors are brought into the building, a modification of this arrangement may be used as illustrated in Fig. 5.

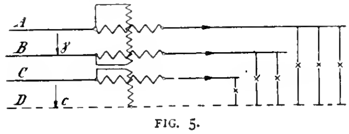

FIG. 5.

In this case a single-phase measuring system is added for measuring the power *Cc*. It is again supposed that no current is consumed between *A* and *B* or *A* and *C*, or *B* and *C*. Both measuring systems, shown in the last illustration, may be easily combined in a single instrument.—*Elek. Zeit.*, November 26.

Influence of the Waveform on the Application of the Two-Wattmeter Method.—BLOCH.—A mathematical article. The two-wattmeter method has the advantages that the power is obtained by means of only two readings; that it is not necessary to get at the neutral point of the system; and that the power factor may be found by a very simple formula from the ratio of the two wattmeter readings. The latter formula does not give, however, the exact power factor, if the e.m.f. and current have wave forms different from a sine wave; the formula gives nearly always larger values of the power factor than if the latter were determined from measurements of current, voltage and power. With loaded induction motors the difference may be up to 5 per cent., according to the wave form. This has the following effect: Modern three-phase motors are generally designed so that when operated as generators with direct-current excitation, they give approximately sinusoidal curves, and they operate as motors with the highest power factor if a sinusoidal e.m.f. is impressed upon them. If such a motor for which the manufacturer has guaranteed a power factor of 0.9, is connected to a network the voltage of which has a wave form differing greatly from the sine form, the power factor will be less than 0.9. By means of measurements with the two-wattmeter method it is possible to ascertain whether the power factor of a three-phase motor is unfavorably influenced by higher harmonics. If this is the case, the above-mentioned formula gives nearly always higher values for the power factor than if determined from power, current and e.m.f. The arithmetical mean between both values is approximately equal to—although somewhat smaller than—the value of the power factor which the motor would have for the most favorable wave form.—*Elek. Zeit.*, December 3.

Galvanometer.—WHITE.—A description of a convenient galvanometer for elementary work which is claimed to be at least as accurate as the Weston milliameter, can be read as quickly and easily, and has the same resistance for a given sensibility. It has the disadvantage that its indifference to outside magnetic disturbances, although great, is not complete. He points out that a reflecting galvanometer has distinct advantages over the old-fashioned tangent galvanometer. The reflecting galvanometer, with smaller deflection and greater radius of the scale, does not require so careful centering of the needle, and hence a small instrument is in this respect as good as a very expensive galvanometer with a pointer. The short needle is more quick-acting. The shortness of the needle and the smaller deflection give a small deplacement of the poles of the needle. The diameter of coil necessary to make the instrument obey the tangent law is thus much reduced. He uses a movable magnet system of two needles, with poles oppositely directed, and adds, of course, a control magnet. For the magnet system the Weiss form has been selected, in which there are two vertical needles, each end of the combination having two unlike poles belonging to different magnets, but acting like two poles of a horizontal magnet, whose length is equal to the distance between the two needles. The needles used are 1.2 mm. thick and 43 mm. long, placed 8 mm. apart. The weight is about a gram. The system is assembled in two or three minutes by laying the needles parallel on two strips of mica and fastening them with sealing wax. The damper is a horizontal wire 4 cm. long, turning in a shallow layer of clear kerosene. For the suspension a small spring is used which weakens the effect of shocks, together with a bundle of eight silk fibres instead of one. In order to make the galvanometer direct reading, the scale is bent to a curve such that distances measured along it are proportional to the tangent of half the angle subtended. The scale is read by the double-mirror system. A small stationary mirror either below and behind or above and in front of the swinging one gives an image of a line somewhere on the scale. There are two coils of the Helmholtz type, each 4 cm. in diameter. Fig. 6 shows the magnetic system with suspending spring and fibres, hemispherical mirror, and damping wire, full size. The upper piece of mica is behind the mirror. The dotted circles show the size of the coils, and the small dotted square shows the position of the stationary mirror.—*Phys. Rev.*, December.

MISCELLANEOUS.

Electric Welding.—An illustrated article in which it is said that the method of electric welding by means of the direct-current arc is comparatively very expensive, since only a small part of the arc is utilized for welding. This method is suitable only if electric power is cheap or for special purposes in which the welding cannot be done as well as by other methods. On the other hand, welding by utilizing Joulean heat is cheaper and in this case alternating current is preferable. Some apparatus of a German firm are described, in which the welding apparatus is provided at the top, while the base contains a transformer, the secondary low-voltage winding of which is made up of large dimensions, so that the loss in it is very small. Such apparatus are made for tube welding, chain welding and other purposes. The larger the cross-section of the surfaces to be welded, the longer is the time of welding and the smaller the current consumption per unit of cross-section. The watt-seconds per unit of cross-section increase with increasing cross-section. It is believed that in workshops in which much welding is to be done the cost of operation together with interest and amortization represents a saving compared with non-electric welding.—*Elek. Anz.*, December 20.

Aluminum.—WILSON.—A note on a lecture on the manufacture and uses of aluminum. The magnetic permeability and the specific resistance of iron can be increased by the presence of a small quantity of aluminum. A mixture of aluminum with ammonium nitrate forms an explosive, the reaction being as follows: The aluminum combines with oxygen to form alumina, and nitrogen and steam are produced in the presence of intense heat, thereby causing enormous expansive forces. The gases formed are harmless.—Lond. *Elec.*, December 25.

The Lorimer Automatic Telephone System.

MACHINERY displaces operators in an automatic telephone exchange. On one plan, it is possible to provide an automatic machine at the exchange for each subscriber which no one else can use. At such an exchange, each separate automatic machine must obviously stand idle during most of the time. Automatic exchanges constructed on this principle must contain a large amount of machinery, unless the mechanism for each connected telephone is very small. In the Lorimer automatic system the idea of separate apparatus at the exchange for each connected telephone is discarded, and the machinery there is devoted to the common use of all the telephone subscribers. This is the most distinct feature of the Lorimer system. A result of this feature is that only enough automatic apparatus is required at each exchange to connect the number of telephones that will probably be required in conversation at any one time. As only ten to twenty per cent of all the telephones connected to an exchange are ever in use at once, the automatic apparatus in a Lorimer exchange, like the number of connecting cords in a manual exchange, is limited by the probable demands for service. This construction with only enough automatic apparatus at an exchange to connect the telephones that are to be

FIG. 1.—TELEPHONE.

engaged in conversation at any one time is fundamental in the Lorimer system. This system consists in brief of a telephone and automatic transmitting device at the station of each subscriber; of automatic connecting apparatus at the exchange which is devoted to the common use of all the subscribers; of two wires between each telephone and the exchange; and of a common return wire to which all telephones and the exchange are joined. Electrical energy for all automatic movements at telephones and at the exchange is supplied by a dynamo or storage battery at the latter, and this is the only source of current in the system. For the extremely interesting data and arguments herewith, we are indebted to the manufacturer's expert staff.

Another distinct feature of the Lorimer system is the fact that the amount of automatic apparatus at an exchange, and the cost of this apparatus, increases in direct proportion to its capacity. Thus, the apparatus for an automatic exchange of 5,000 subscribers costs only ten times as much as the apparatus for an exchange of 500 subscribers. As regularly manufactured the automatic apparatus is in sections, each of which is suitable for 100 subscribers. These sections are all exact duplicates of each other, and an exchange started with one or more sections may add new sections up to any capacity as the number of subscribers increases. This addition of new sections requires no change as to those already in use, no matter how far the addition is carried.

In operation this automatic system is prompt, accurate, secret, continuous, and free from interruption. Connection between any two telephones on the system is completed within eight seconds after a call is made at either of them. The telephone connected to a calling line is certain to be the number called, because the automatic operation of the exchange is guided entirely by the number for which the indicator on the calling telephone is set.

As each call is received and the connections are made entirely by automatic machinery that is common to all of the subscribers, it is impossible for any one at the exchange to find out who is calling or being called at any time. Much less can any one at an exchange hear any conversation between two connected telephones. As each telephone has its own separate metallic line, no one at a third telephone can hear what is said between two that are connected.

No attention by any attendant is required when a call and connection are made, so that the automatic exchange is in a position to give continuous service day and night, no matter how small the exchange may be. Having been connected by the automatic exchange, the two telephones remain connected until the receiver at one of them is hung upon its hook. No third telephone of the system can either break the connection between two that are engaged in conversation, or secure any connection with their lines.

Any subscriber may call and be connected with any other on the automatic system without the intervention of further human agency. To do this the sliding pointers on a plate having four rows of figures, each from 0 to 9, inclusive, are set over the figures that go to make up the number of the telephone called, beginning at the left hand side. Thus, in the cut, the pointers are set to call the number 5,276. The next move is to press a lever that projects at the right-hand side of the telephone box down to its lowest position.

This lever immediately begins to rise, and as soon as it reaches the original position the receiver should be placed to the ear and the ringing button, located near the lower edge of the indicator plate, should be pressed. If the called telephone was busy so that connection with it could not be had, the receiver of the calling telephone will yield no sound when the button on its indicator plate is pressed. If the calling and called telephones have been connected by the automatic exchange, a distinct vibration may be heard at the receiver of the calling telephone when its ringing button is pressed. This vibration indicates that the bell on the called telephone is ringing.

The person holding the receiver of the calling telephone thus knows when the bell of the called telephone rings, because he hears it. To make these movements at the calling telephone requires less time than is consumed by communication with the central operator in a manual system. Either of two connected telephones may be immediately disconnected and left ready for a new call by hanging its receiver on the hook.

If in any case all of the automatic apparatus in the section to which a calling telephone is connected at the exchange is momentarily in use, the lever at the side of the telephone box will not rise until a division of the automatic apparatus is released. As soon as this happens the connection is completed between the calling and called telephones without any further effort on the part of the person calling. In other words, a call when once made is stored by the automatic exchange until the connections can be completed.

Besides an ordinary receiver, transmitter and call bell, the telephone of each subscriber on the Lorimer system includes what is termed a signal transmitter. This transmitter is a device for automatically making and breaking the signaling circuit, and includes a circle of contact pins set in insulating material, an arm that moves over these pins, a spiral spring that actuates this arm, a pawl that holds it, and an electromagnet that disengages this pawl when current from the exchange enters its windings.

The indicator plate and its four sliding brushes already mentioned, are in constant electrical connection with the common return wire that runs between the exchange and every telephone of the system. When either sliding brush is set over any one of the ten figures near its slot, a certain one of the contact pins in the circle is put into electrical connection with that brush and consequently with the common return wire. Between the forty pins that correspond to the forty figures on the indicator plate there are interposed dead pins, so that the contact arm in passing over them rests alternately on a dead pin and then on a pin corresponding to one of the figures on the indicator plate.

Besides the dead pins and those that correspond to the forty figures on the indicator plate, the circle contains what are known as the normal pin, the preliminary pin, and the talking pin. The normal pin is the one on which the revolving contact arm rests when the telephone is not in use, and this pin is connected to the No. 2 wire of the telephone through its call bells and a switch. At each telephone the No. 1 wire is connected to the arm that revolves over the circle of pins through a switch which is operated by the receiver hook.

The No. 2 wire is connected to this last named switch through the receiver, transmitter and the ringing key, so that when the receiver is on its hook the Nos. 1 and 2 wires of the telephone are connected through the revolving arm, the normal pin and the call bells, provided the level at the right side of the telephone is in its normal or highest position. Unless the revolving contact arm is on either the normal pin or the talking pin, the receiver hook remains locked in its lowest position even though the receiver is removed. Unless the receiver hook is in its lowest position the lever at the right of the telephone cannot be moved to make a call.

An automatic exchange for any number of telephones in the Lorimer system is made up of duplicate sections with capacity for 100 telephones each.

Each section is mounted on a steel frame, occupies a floor space of about 1½ by 10 ft., and is 4 ft. high. In large exchanges the sections are placed front to back with sufficient room left between them for a passageway. The space occupied by each section is about 1½ by 8 ft. and is 4 ft. high, and weighs approximately 1,000 lbs. The construction of the frames and sections is made up entirely of metal and insulating materials, and no wood is used in any part. Each section

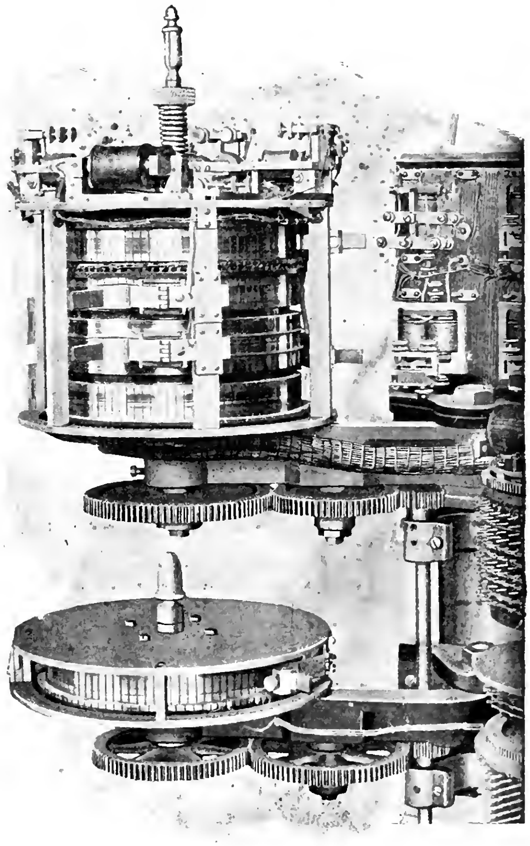

FIG. 2.—DECIMAL INDICATOR.

includes one horizontal and six or more vertical shafts, according to the percentage of the connected telephones that is assumed to be required at any one time. If the section provides for conversation between any ten of its connected telephones at the same time, then it will carry six vertical shafts. The vertical shafts are all geared to the single horizontal shaft, and revolve constantly with it when the exchange is in operation. The speed of these shafts is 50 r.p.m. All of the sections in an exchange are driven from a common source of power, and where there are only two sections the power may be derived from an electric motor mounted on their common frame.

Not more than 1/8 hp is required to operate the shafting and other parts of each section.

Each vertical shaft of a section is adapted to drive a row of automatic circular switches or circuit changing devices by means of electrically operated clutches, that start and stop the switches as required. The left-hand row on the front of a section contains four of these circuit changing devices, and is called a sectional division. Each of the other vertical rows of apparatus in a section contains five circular switches, and is called a percentage division. The office of the sectional division is to respond to the call of any telephone in its section, by starting a chain of automatic movements by which one of the idle percentage divisions connects the calling and the called telephone. In other words, the sectional division responds to the call of any one of the entire 100 telephones in its section, and transfers this call to any one of the five percentage divisions, all of which can connect ten telephones in pairs at any one time. Thus, by reason of this action of the sectional division, only five percentage divisions are necessary to do the work that would require fifty percentage divisions if one of these divisions was provided for each pair of connected telephones. Only seven percentage divisions are provided ordinarily on each section, because experience shows that not more than ten per cent of all the telephones connected to a system are commonly in use at the same time. And in consideration of the fact that the clearing out apparatus is instantaneous seven divisions will have a larger capacity than the ten per cent of cords and plugs usually provided in manual practice.

FIG. 3.—CYLINDER SWITCH.

Each percentage division of a section corresponds to one of the connecting cards at a manual exchange, with this difference: The cord can connect two telephones only when it is put into position by an operator, while the percentage division, actuated through the sectional division, takes a position automatically that connects the calling and called telephones. Just as in a manual exchange it is only necessary to have enough connecting cords for the percentage of all the telephones that will be in use at any one time, so in a Lorimer automatic exchange it is only necessary to have a corresponding percentage of the so-called percentage divisions. Were it not for the application of this percentage principle, fifty of the so-called percentage divisions would be required for each 100 subscribers, since one of these divisions connects two telephones, but the actual requirement is only five percentage divisions for each 100 subscribers. It also provides for the application of the placing of the telephones of an exchange on sections of different capacity as determined by their use. Thus the business telephones can be connected to sections having ten or more percentage divisions and the residence ones to sections having 3 or 4 percentage divisions. By this arrangement a large saving is made in the initial cost. In the same way those who are known to abuse the use of the telephone by long continued conversations may be assigned to a section having an automatic conversation limit apparatus which will disconnect them after the lapse of a certain time.

Of the four circuit changing devices that go to make up a sectional division, three consist of commutators and contact rings mounted in metal clamps, and one is a commutator or circular switch whose segments or contact parts consist of strips of German silver set radially in a hollow cylinder of insulating compound. Within this hollow cylinder a revolving brush makes contact with the ends of the German silver strips. Each percentage division contains five of these cylindrical switches with German silver contact strips, as just mentioned. As these switches make up the great bulk of all the apparatus at the automatic exchange, the simple and substantial character of their construction is important. In their main parts all these cylindrical switches are duplicates ,and each includes a hollow cylinder of insulating compound with 528 strips of German silver mounted symmetrically and radially therein, so that their ends project at both the inner and outer surfaces of the cylinder. Each cylinder of insulating material is 6¾ inches in outside and 4¼ inches in inside diameter, and is 3 inches long between metal end discs. These German silver contact strips are punched from sheet metal, and each strip is 1 15/16 inches long, 3-16 inch wide at its interior, and ⅛ inch wide at its exterior end. Between the interior ends of radially opposite strips the diameter of the cylinder is 3⅝ inches, and the diameter over their exterior ends is 7½ inches. The 528 strips are arranged in twelve circles of 44 strips each, the sides of the strips being in the planes of these circles.

Within each circular switch is an aluminum spider that carries a number of brushes mounted radially in a clamp of insulating material, and each brush consists of two strips of German silver so placed that they make hard wiping contacts with both sides of each strip in a certain row of the cylinder, when the spider is revolved. Each of these brush spiders takes its motion from one of the vertical shafts whenever it is mechanically connected thereto by the operation of an electric clutch. The shafting of each section and the brushes on the decimal indicator are normally in motion, but the other automatic apparatus moves only in response to a call, and then comes to rest. The contact surfaces thus wear only in proportion to the number of calls. The contacts between these German silver brushes and strips are included in the talking circuit between two connected telephones, and form the greater part of the wearing surfaces in the entire exchange. The cylinders of insulating compound are quickly and cheaply made by casting them in a metal mould that holds the

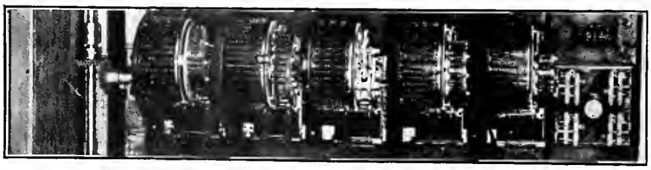

FIG. 4.—PERCENTAGE DIVISION.

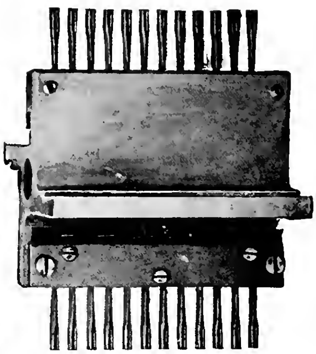

FIG. 5.—BRUSH FOR CYLINDER SWITCH.

German silver strips in their proper positions until the compound hardens.

The wearing qualities of these cylindrical switches is illustrated by the one shown in the cut, whose spider was placed within the cylinder and then revolved by a lathe to an amount corresponding with 23,000,000 calls. This switch remains in good serviceable condition.

The Nos. 1 and 2 wires from the 100 telephones of a section are all connected to cylindrical switches in each of the percentage divisions, each contact being made by soldering a wire to the outer end of one of the radial strips of German silver. Wires used to make these connections are cotton, silk and paraffine insulated, and those entering each cylinder switch are carried through a distributing ring of hard fibre at its lower side. Beneath this ring the wires are brought into a cable, and then pass to numbered holes in a strip of fibre on the back of the steel frame of the section. All of the strips are arranged in regular order, and as the holes in them are numbered the connection of wires from the telephones to those that terminate in the strips is a very simple matter. As all of the wires that run to the several switches of each section are in plain sight and arranged in regular order, tests for breaks or other troubles are easily made. In the connection of a new section at an exchange it is only necessary to bring the two wires from each of its 100 telephones to the terminals of wires in the fibre strips, and to join the new section to the others by a cable of forty wires that also come to the fibre strips.

In each sectional division, the piece of apparatus which receives the first impulse from a calling telephone, and sets in motion the chain of automatic operations that completes the desired connection, is called the "decimal indicator." This indicator includes three commutators of 100 segments each, one commutator of ten segments, and two battery contact rings. These commutators and rings are held in a stationary position about a central revolving shaft, and a concentric frame carrying brushes is driven by this shaft through a friction clutch. One of the 100 segment commutators on a decimal indicator is called the "line ring," and the No. 1 wire from each telephone of the section is connected to one of its segments. A storage battery at each exchange supplies current for the automatic apparatus there and at the connected telephones, also for conversation. The system is thus operated entirely with central energy. A battery of 30 volts is ordinarily employed, and the poles of the battery are connected respectively to the two contact rings of the decimal indicator. One terminal of the storage battery is also connected to the common return wire that joins the exchange with every telephone on the system.

When the lever at the right-hand side of a telephone is pulled to its lowest position, the automatic operations that connect the calling and called telephones begin. This movement of the lever at a telephone connects its No. 1 wire to the common return wire. As the brush frame of the decimal indicator is normally revolving at the rate of 15 r.p.m., each segment of its line ring comes under the brush that travels on that ring once every four seconds. When the brush on the line ring reaches a segment whose connected wire, the No. 1 wire of a telephone, is joined to the common return wire at that telephone, the poles of the storage battery are united through these wires and the winding of an electromagnet. The action of this electromagnet releases the clutch through which the brush frame of the decimal indicator is driven, and this frame comes momentarily to rest with its brush on the segment of the line ring to which the No. 1 wire of the calling telephone is connected. In this position of the brush frame certain circuits are closed by the brushes that rest on segments of the other commutator rings of the decimal indicator, and currents in these circuits actuate magnets that bring one of the idle percentage divisions of the section into operation. The position or segment on which the brushes of the decimal indicator are brought to rest gives an indication on a percentage division of the line calling, and connects that calling line to apparatus on the percentage division through which the called line may be found. At the same time the winding of the magnet of the signal transmitter at the calling telephone is closed on the battery through its No. 2 wire and the common return, and the stop that holds the lever of this telephone in its lowest position is thereby released. When the lever at the side of a telephone is drawn to its lowest position, a spring is compressed which tends constantly to restore the lever to its highest position. Such return of the lever is impeded by a stop, which may be released by the action of the magnet last named and controlled by the exchange apparatus. The momentary closing of the battery circuit through the No. 2 wire, the common return wire, and the winding of this magnet at the calling telephone allows the lever to rise one step, and it is then engaged again by its stop. Movement of the telephone lever to its lowest position forces the revolving arm of the signal transmitter from the normal pin to the preliminary pin in the circle of pins already mentioned, and thereby makes the connection between the No. 1 wire and the common return. When the

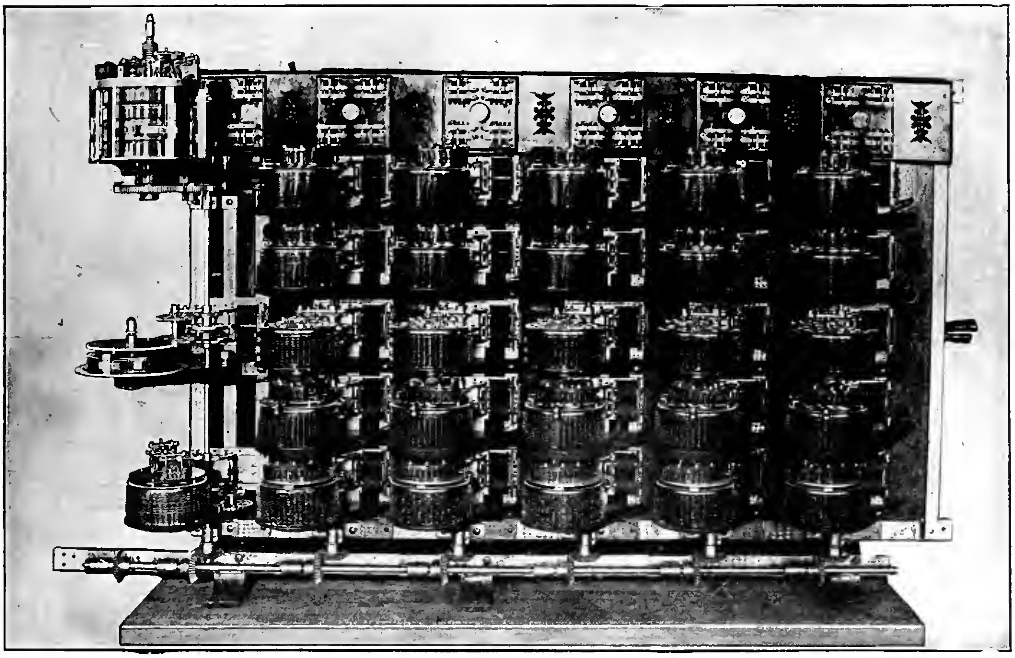

FIG. 6.—FRONT OF SECTION.

telephone lever rises one step from its lowest position it moves the contact arm away from the preliminary pin, and thus breaks the connection between the No. 1 wire and the common return. The moment current ceases in these wires the clutch on the decimal indicator is released, and the brush frame begins to revolve. The decimal indicator is thus ready to receive another call and start a new series of automatic operations for the connection of a different pair of telephones, as soon as the lever and contact arm of the telephone that last called have made their first automatic movement.

The series of automatic movements, put into operation when the decimal indicator stops its revolution in response to a call, are continued by parts of the sectional division and by a percentage division after the brushes of the indicator resume their motion. By these automatic movements, the winding of the magnet at the calling telephone is intermittently excited ,and the lever at the side of the telephone gradually rises step by step, and causes the contact arm to revolve over the circle of pins that correspond to the figures on the indicator plate. This contact arm, after leaving the preliminary pin, passes first over the quadrant of pins that correspond to the thousands figures, and then in succession over the quadrants that correspond to the hundreds, tens and units figures, respectively, of all the telephone numbers in the system. Whenever the revolving arm makes contact with a pin that is connected with the common return wire through one of the pointers that has been set over a figure on the indicator plate, the No. 1 wire is united to the common return at that telephone. In the circuit thus formed a current flows that causes the percentage division that has taken up the call to complete a contact there that corresponds to one figure in the number of the called telephone. When the lever at the calling telephone has risen to within one step of its normal or highest position, the revolving arm has passed over the four quadrants of pins that correspond to the four numeral places on the indicator plate, and the percentage division engaged in the call has completed connections at the exchange that correspond to the number of the called telephone. The result of these movements is that the Nos. 1 and 2 wires of the calling telephone are connected to one winding of a repeating coil at the exchange, and the Nos. 1 and 2 wires of the calling telephone are connected to the other winding of this same coil. At this point in its revolution the contact arm reaches the talking pin, and the No. 1 wire is thereby connected to the common return, so that the automatic apparatus at the exchange prevents interruption of the connections between the calling and the called telephone.

The lever at the calling telephone having risen to within one step of its normal or highest position, comes to rest, and the call may now be completed by taking the receiver from its hook and pressing the button on the indicator plate. Pressure of this button starts an alternating current through the No. 2 wire, the common return, and the call bells of the called telephone, and this current, passing through one winding of the repeating coil at the exchange, induces current in the other coil that flows through the Nos. 1 and 2 wires of the calling telephone. This induced current causes the sound that may be heard in the receiver of the calling telephone when the button there is pressed, after the automatic connections have been made. When conversation has been finished, the receiver should be returned to its hook, and the lever at the telephone that made the call will then rise one step to its normal position, while the contact arm of the signal transmitter moves from the talking pin to the normal pin. At the same time the percentage division through which connections were made at the exchange resumes its normal condition, and is then ready to take up another call from the decimal indicator.

The Lorimer automatic system has some advantages that especially concern the engineer and investor, while others appeal directly to telephone users. Perhaps the greatest advantage claimed from the standpoint of an operating company is the entire saving of the wages of telephone operators. This saving is not cut down by the wages of skilled engineers to keep the automatic apparatus in order, for one attendant is able to keep an automatic exchange for 2,000 telephones in working condition. Neither do repairs and depreciation of the automatic exchange represent a large offset to the saving from operators' wages, because of the simple and duplicate character of the cylinder switches which make up the great bulk of the automatic apparatus. Second only to the saving in the wages of operators is the advantage of a possible increase in an exchange from the smallest to the greatest capacity without discarding or changing any of the older sections as new sections are added. Furthermore, an increase of exchange capacity in this system increases the first cost only in direct proportion to the capacity. In other words, the automatic exchange, be it large or small, costs so much per section with a capacity for 100 telephones. In a manual exchange, as is well known, the cost per connected telephone goes up more nearly as the square

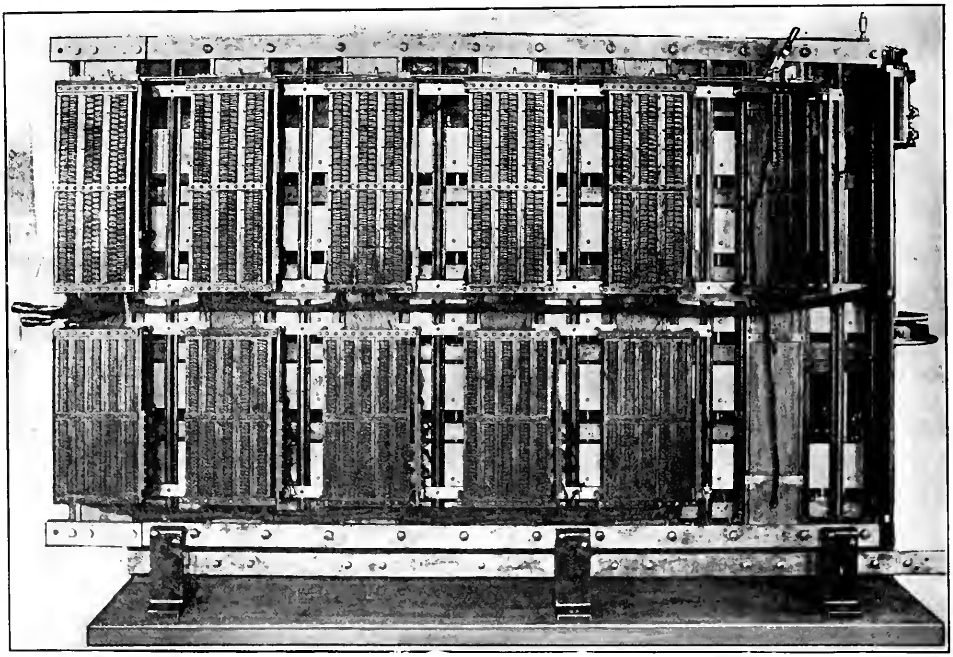

Fig. 7.—Back of Section.

of the number than in direct proportion to it. As each automatic section has all internal connections completed before it goes from the factory, and only connections to its numbered terminals are made at an exchange, the cost of installation is much below that for a manual board of equal capacity. In this automatic system there is no reason to install a large exchange at the start and then wait for the business to grow, but the capacity may be increased from time to time as wanted, by the addition of sections for 100 telephones each. Besides the foregoing, the automatic exchange has the very obvious advantage that its service cannot be interrupted by strikes or labor troubles with operators.

To telephone users this automatic system offers advantages in prompt, continuous, secret service, that do not exist in manual exchanges. In a manual exchange the service may or may not be prompt, in the automatic exchange it must be prompt. In a manual exchange, the cost of night operators may prevent continuous service; in the automatic exchange there is no corresponding cost. In a manual exchange the service cannot be secret, in this automatic exchange it cannot be other than secret.

While the circuit of a telephone in use may be interrupted at any time in a manual exchange, such a circuit can only be interrupted by hanging up its receiver if the telephone is connected to the automatic exchange.

With a manual exchange reasonable rates must rise with the number of connected telephones, but with an automatic exchange the investment increases directly as the capacity, and reasonable rates should remain constant.

The Lorimer brothers have devoted nearly a decade to the invention of the automatic telephone here described, and their ideas have been carried out by skilled mechanics in a well equipped factory.

As the perfected system stands to-day, ready for the market, it represents a cash outlay of several hundred thousand dollars. The Lorimer system is covered by patent applications in the United States and many foreign countries. These patents, save that for Canada, are owned and the system is manufactured by the American Machine Telephone Company, Limited, of Piqua, Ohio.

Mr. N. D. Neill is president and general manager of this company, Mr. C. J. Kintner is vice-president and Mr. G. W. Lorimer is secretary, treasurer and electrical engineer. Rights covering the manufacture and sale of the Lorimer apparatus in Ontario and Quebec have been acquired by the Canadian Machine Telephone Company, Limited, of Toronto, Canada. This company has fitted up a factory for the manufacture of the automatic apparatus, has the construction of several exchanges under way, and one in operation in Toronto.

The Voltaphone.

The Stanley Electric Manufacturing Company has placed on the market a new type of instrument, named the "Voltaphone," which combines the functions of voltmeter, telephone and clock. In keeping track of the drop of potential at distributing centers, the usual practice has been to send out men with portable instruments to the various sections where energy is distributed, and have them telephone voltage readings to the station attendant during the periods of changing loads at these points, the station man making record of these reports, and adjusting his apparatus as best he could to meet these requirements. The voltaphone performs the same service that an attendant would if he were stationed with his voltmeter and telephone at the same point, and were in communication with the station operator.

The voltmeter side of the instrument is connected to the service in the usual way, and the telephone connections are made the same as in regular telephone work, usually requiring but a few minutes to install the voltaphone for operation, provided a telephone line between the distributing center and the generating station is available. The telephone wire should be continuous between the voltaphone and generating station during the hours that voltage readings are to be taken; that is to say, it should not be necessary for the generating station to ask the telephone operator for connection with the instrument whenever readings are desired. It does not interfere with the use of the line for other service, and if several voltaphones are to be used on the same telephone line, they can be arranged with a system of polarized relays, and any sub-station can be called up as desired, or the instruments can be made so that they may be set to announce at specified times, thus enabling the attendant to learn, as often as is deemed necessary, the exact condition at the centers of distribution. The clockwork of the instrument should be wound as often as necessary, probably every day, the mechanism giving 75 to 100 readings with one winding.

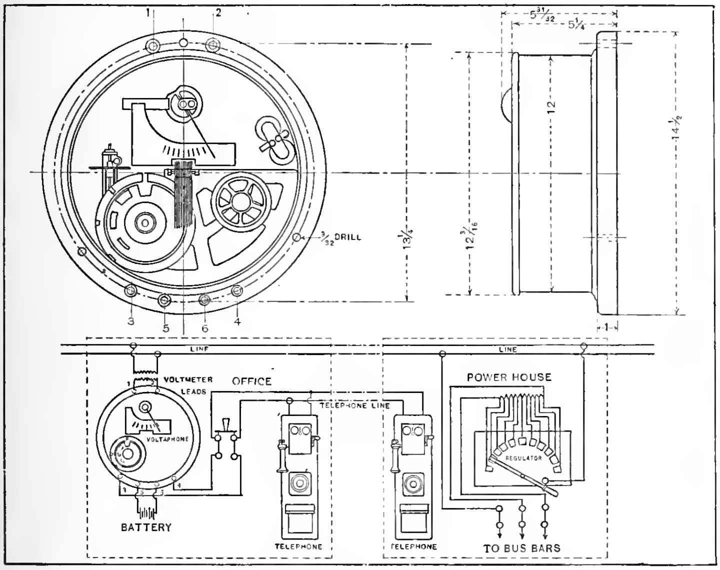

FIG. 1.—DIAGRAM OF VOLTAPHONE CONNECTIONS.

FIG. 2.—VOLTAPHONE.

The instrument is made to suit the conditions under which it is to be installed. The voltmeter is made for the desired voltage, and the telephone relay is wound to work in harmony with instruments in use, and is also made to respond to signal or to announce at certain predetermined periods. It is furnished with either a gramophone disc, which gives the readings in words, or with a signaling disc, which gives the readings in dots and dashes, easily understood, and capable of being distinguished when, from line troubles, the spoken words might be unintelligible.

The signals are those commonly known in telegraphic practice as dots and dashes. For example: One dot, or short sound, signifies that the voltage is 1 per cent. high; two dots, 2 per cent. high; three dots, 3 per cent. high; four dots, 4 per cent. high; while one dash, or long sound, indicates that the voltage is 1 per cent. low; two dashes, 2 per cent. low; three dashes, 3 per cent. low; four dashes, 4 per cent. low. One continuous sound indicates that the voltage is normal. The instrument also indicates if the voltage is above or below this range.

In operating the voltaphone, the station attendant rings up on his telephone in the usual way, and this sets in operation the instrument, which immediately gives him the voltage at its end of the line and repeats the reading, requiring about one-half minute for the two readings. If the voltage changes after the first signal, the second indicates it, making it feasible to change the voltage after getting the first signal, and to note the result of such change in the second signal.

The details of construction have been carefully worked out, and, considering the service performed, the mechanism is very simple, only such parts being used as are found to be reliable in the well-known instruments that are combined to form the voltaphone. The intention has been to furnish a practical instrument at a reasonable cost, which can be used on any telephone or telegraph line, to convey to the power house reliable information of conditions at a distant point.

Single-Phase Condenser Motor.

We illustrate herewith the latest type of General Electric single-phase motor for general power purposes, from 1 up to 15 hp. and especially designed for operation on lighting circuits. By the use of condensers and a starting resistance in the armature circuit, the result is a starting current which does not exceed that of full load, and a high power factor at all loads, thus eliminating the lagging currents common to other motors of the induction type, especially at light loads.

This type of single-phase motors differs from other types in which condensers have been employed, in that the condensers are not connected in shunt with the motor, but are energized by a tertiary motor circuit in which current is induced. In consequence, the motors

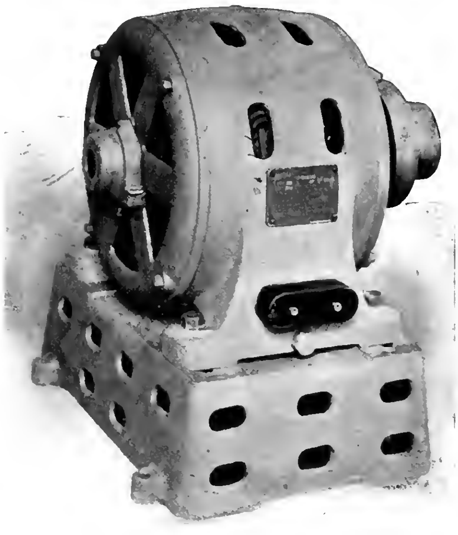

Fig. 1.—Single-Phase Condenser Motor.

do not require the sine wave of e.m.f. necessary when the shunt method of connection is employed, but may be operated with equal satisfaction on any e.m.f. wave form. Neither compensators nor any other auxiliary devices are used with the motors, the form of field winding being such that the condensers can be connected directly to the motor. The condensers are sealed in air-tight tin cases, impervious to moisture, and located in the sub-bases.

Low starting current is obtained by means of a coil-wound armature in which is placed a resistance. This resistance is in series with the armature winding at the time of starting, and is automatically cut out before normal speed is attained, by a centrifugal switch contained in the armature. With this method of starting, the motors are entirely automatic, and should the circuit be interrupted and again completed, the motors will start without the slightest attention.

To obtain full-load starting torque, a clutch pulley composed of two parts is employed. One part is a split ring which is attached to the shaft and revolves with it; the other part consists of the pulley face and an outer shell. This shell being free upon the shaft, remains stationary until the armature has attained a considerable speed, when the ring expands, gripping the shell and causing it to revolve with diminishing slip as the speed of the armature is increased, until they both revolve at the same speed. A pulley of different diameter may be used by simply removing the outer shell and substituting one having a pulley of the desired diameter. The standard pulleys should be used wherever possible, as they are properly proportioned for the various motors.

It is sometimes desirable or even necessary to suspend the motor from the wall or ceiling and these motors are constructed to readily

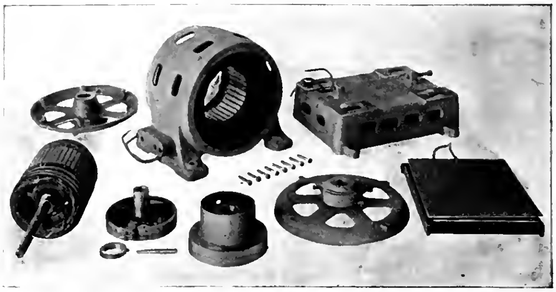

Fig. 2.—Elements of Motor.

meet these requirements. They may be prepared for wall or ceiling operation by simply loosening the end shields and turning them 90 or 180°, respectively. The importance of this feature in connection with an installation in mills or factories where space is limited will be quickly recognized. The motors lend themselves very readily also to direct connection to centrifugal pumps, generators, etc., the connection being accomplished by means of a clutch coupling. They can also be geared or belted to very slow-speed pumps and other machines.

The standard windings are as follows: All sizes up to and including 3 hp are wound for 110 volts, and the larger sizes for 220 volts; the standard frequency is 60 cycles. The motors will operate satisfactorily over a range of voltage or frequency 10 per cent. either above or below normal. It should be remembered, however, that a low voltage and high frequency or the reverse have an accumulative effect, and the variation referred to should cover the sum of the variations.

Most induction motors give rise to lagging current, which increases the current taken by the motors and causes the apparent power input to exceed the real power input. The ratio of the real to the apparent watts is called the power factor. The idle current is not in phase with the e.m.f., and, therefore, represents no loss of energy except that absorbed in heating the conductors, but it may have a detrimental effect upon the regulation of the system, or assume such proportions as to seriously diminish the useful output of the station. With the present type of single-phase motor, however, the question of power factor has been given special attention and idle currents have been reduced to a minimum, and in the larger sizes they have been entirely eliminated. In the sizes smaller than 7½ hp, the currents are lagging and the power factors range from 50 to 90 per cent. from no load to full load, respectively. In the larger sizes, however, the power factors range from 70 to 100 per cent., and the current at fractional loads is leading, which tends to improve the power factor of the circuits from which inductive loads are operated. The efficiencies, moreover, of single-phase motors are much higher than those of other single-phase motors.

The speed of an alternating-current motor varies with the frequency and is not materially affected by variations of voltage. It cannot, therefore, exceed normal if the frequency remains constant. The temperature rise of the motors will not exceed 40° C. under continuous operation at full load. This moderate increase allows liberal margin for overload without excessive heating. The motors can be operated from the same transformers as arc or incandescent lamps, or they can be supplied with separate transformers. In either case 1 kw capacity of transformer is allowed per horse-power of motors installed.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—Stocks recovered from the depression caused by the passing of the dividend on United States Steel common and the unfavorable financial statement of the corporation, and at the close the market was steady. There were no features of particular interest. Money eased off materially and as soon as the January payments had been concluded call loans fell to between 3 and 4 per cent., while time money was offered freely. It has been remarked that the suspension of the Steel Corporation dividend had more effect on the general list of stocks than upon Steel itself and the other industrials. The manipulative support in Amalgamated Copper and Brooklyn Rapid Transit was kept up, those stocks being rather strong features. The sales of Brooklyn Rapid Transit were 151,750, the closing price being 53¾, a net gain of 2 points. Metropolitan Street Railway was quiet, closing at 122, this being a gain of ½ point. General Electric was inactive throughout the week, the sales amounting to only 2,910 shares. This stock closed at 174, thereby losing 2 points net. Westinghouse common gained 4 points and preferred 1 point, the closing figures being 172½ and 192, respectively. Western Union made a gain of 1½ points, closing at 88, and American Telephone & Telegraph ⅛ point, the closing price being 126. Following are the closing quotations of January 12:

WIRELESS TELEGRAPH CONSOLIDATION.—At the annual meeting of the International Wireless Telegraph Company at Trenton, N. J., on Jan. 6, a resolution to consolidate with the American De Forest Wireless Telegraph Company was adopted without a dissenting vote. The Greater New York Security Company will finance the consolidation. The International stockholders, it is said, will receive $7,500,000 of stock in the new concern and have an interest in about seventy patents. Vice-president and general manager Gehring reported that instruments of the American De Forest Company had been ordered by the Belgian, Swedish and Japanese Governments and that the London *Times* had two sets ordered in anticipation of war in the Far East. The following directors were elected: Dr. G. G. Gehring, H. Shoemaker, M. Van Boskirk, William J. Hopper and John Mayhew. The consolidation was effected by the issuance of shares of the De Forest for shares of the International Wireless on a share-for-share basis. The International was organized originally as the American Wireless Telephone and Telegraph Company, with a capital of $5,000,000. It obtained control of five subsidiary companies—the Northeastern, Atlantic, Northwestern, Pacific and Continental—each organized on a five-million-dollar basis, and was subsequently reorganized as the Consolidated Wireless Telegraph and Telephone Company, with a capital stock of $25,000,000, through exchange share for share of the stocks of the controlled companies. This was later reduced to $7,500,000. Throughout these changes the stock had been offered to the public, and when the Consolidated was formed further stock offerings were made. Then came, a year later, the organization of the International Wireless Telegraph Company, with a like capitalization, which is now superseded by the acquisition of the latter by the American De Forest. The shares of the International and De Forest have a par value of $10. The actual value time must prove.

MICHIGAN TELEPHONE SALVAGE.—Last week the bondholders' committee of the Michigan Telephone Company, which recently acquired at foreclosure sale the properties of the corporation, were in session at the office of N. W. Harris & Company, New York City, working out a plan of readjustment of the various interests involved in the company's affairs. The property was bid in by the bondholders' committee at $4,100,000, and had been valued at something like $10,000,000 by minority stockholders' representatives, who subsequently made an ineffectual effort to have the sale annulled. The majority of the stock of the Michigan Telephone Company is owned by the Western Telephone Company, 51 per cent of whose stock is owned by the Bell. There is also a floating debt of $2,400,000 for money advanced by the Western Telephone Company besides accrued interest. No statement of the plans under consideration was given out by the bankers, who are managers of the bondholders' syndicate. Allen W. Forbes, of N. W. Harris & Company, said that negotiations had not progressed far enough to admit of such a statement, and that all accounts of an alleged plan of reorganization were unauthorized. The outline of the plan alluded to came as a Detroit dispatch to a Wall Street news agency. It stated that the bondholders will receive an equivalent of par and interest for their holdings, and will have an option of taking new preferred stock to the extent of from $1,000,000 to $1,500,000, the issue being made for the purpose of providing working capital. With the new preferred stock the company would have a total issue of $6,500,000.

MASSACHUSETTS STREET RAILWAYS.—The Massachusetts Railroad Commissioners report as follows on the street railways of the State:

	1903.	1902.	1901.	1900.
Pass. car.	....	465,472,382	433,526,935	395,027,198
Car mls. run	....	100,280,687	93,005,225	81,750,768
Gross	$27,027,651	$24,918,684	$23,179,304	$21,387,641
Op. ex.	17,519,367	15,912,852	14,565,141	13,159,947
Net	$9,508,284	$9,005,309	$8,614,163	$8,227,694

Balance	$3,602,916	$3,388,851	$3,398,183	$3,037,502
Dividends	3,586,248	3,138,711	3,417,117	2,409,874
Surplus	$16,668	$250,140	Df. $198,340	$627,628

CHICAGO ELEVATED TRAFFIC.—Chicago's elevated electric railroads broke all previous monthly records in December, except in the instance of the South Side Elevated Company, whose figures for November were not equalled. For the full year this road's gain was 10,714 passengers per day, or 13.65 per cent over 1902. The Metropolitan showing was not so large. For the year the gain was 6,543 passengers a day, or 6.19 per cent. The Northwestern increased its traffic 4,652 passengers per day during December, and the daily average for the year was 4,324 passengers in excess of the average showing for 1902.

KEYSTONE TELEPHONE.—The Keystone Telephone Company, the first organization to actively compete with the Bell Company in Philadelphia in recent years, has completed a full calendar year of operations, 1903. The net earnings reported by the company for the calendar year ended December 31, 1903, (December partly estimated) are $230,418, which is twice the amount required to pay a 5 per cent dividend on the $2,500,000 preferred stock. No further steps have been taken about a bond offering.

CONTINENTAL CONSOLIDATION.—A cable dispatch from Paris of Jan. 9 says: "As a result of recent negotiations it is announced that the Mediterranean Thomson-Houston Company and the German Société Génerale d'Electricité have been amalgamated. The new company will have a capital of $1,200,000. There has been no conclusion of the negotiations for the amalgamation of the French Thomson-Houston Company into the combination, but no hitch has occurred, so far as is known."

EMPIRE CITY SUBWAY.—The Empire City Subway Company, Limited, of New York City, filed with the Secretary of State on January 13 a certificate of an increase of capital from $2,750,000 to $3,500,000. The certificate is signed by William T. Bouchelle, John H. Cahill, Joseph P. Davis, and John W. Lieb, Jr.

MERCANTILE ELECTRIC COMPANY ELECTION.—At a meeting of the Board of Directors of the Mercantile Electric Company last week, William H. McIntyre was elected a vice-president and Alvin W. Krech was elected a director.

TWIN CITY RAPID TRANSIT.—The Twin City Rapid Transit Company has completed plans for an extension of its system and will expend $1,500,000 on the project. The first extension will be a line from Minneapolis to Excelsior, on Lake Minnetonka, one of the great pleasure resorts. The line will ultimately be extended to Anoka and Shakopee and will take in several towns. Power will be derived from dams at Elk River, which have already been acquired and upon which work has begun. This and a new line between St. Paul have been agreed upon. There are two direct lines now between the Twin Cities, but the accommodations are inadequate at times during the summer season, and will so continue until a new line is built or more power houses are erected.

Commercial Intelligence.

THE WEEK IN TRADE.—Trade at the opening of the year, while not particularly active, shows a predominance of satisfactory features. The cold and stormy weather, which generally prevailed in the first week, had a considerable retarding effect on business and a disorganizing influence on transportation. Wholesale business is seasonably quiet at leading Eastern and Central Western markets, but a noteworthy feature is the spring demand and shipments already begun at the Southwest. Collections show a slight improvement and money is easing up, supplies of that commodity being better than heretofore. The outlook for the spring, while conservative, is favorable. The war talk has been a stimulus to many markets, especially those for cereals and provisions, but securities and cotton have been depressed by the same influences. Iron and steel, in the cruder forms, were steadier and though quiet in the East there was a better demand in the West for finished forms. As an indication of the future expansion of agriculture it is notable that Western and Southern plow manufacturers are buying more freely and interests catering to Southern trade have begun to run overtime to fill orders. The industrial situation on the whole looks somewhat better, employees showing a disposition to accept modified wages, and a number of iron and steel mills and furnaces are resuming on a readjusted basis of cost. Railway earnings for December last indicate a 7 per cent. increase over those of 1902, and the final returns for the entire year are fully as good as those foreshadowed in earlier weeks. The business failures for the week ending January 7, as reported by *Bradstreet's*, numbered 262, against 209 the week previous, and 336 the corresponding week last year. The same source of information notes the fact that the week's failures sum up the smallest total reported at this period for three years past. Complete failure returns for the year show a reduced number of casualties, though a larger volume of liabilities than in the previous year, the latter based upon an increased number of financial suspensions of concerns "on paper capital" and a few failures of large manufacturing concerns. Trade on the Pacific Coast is good in all lines except lumber, and with the Orient it is expanding largely. Copper developed considerable strength and there was considerable buying by consumers here and abroad. Prices have advanced, the closing quotations being 12⅜ to 12⅝c. for Lake, 12¼ to 12½c. for electrolytic, 12 to 12¼c. for cathodes, and 12 to 12⅛c. for casting stock.

TELEPHONES IN POST OFFICES.—A special dispatch from Cleveland, Ohio, of January 12 says: "The order of Postmaster-General Payne, which bars from the Post Office of the United States all independent telephones has raised a row. The order prescribes that only the instruments of the companies that have long-distance connections with Washington shall be used. In the Middle and Western States the independent companies have a very extensive service and their charge of discrimination is being taken up by Congressmen. Cleveland, as the headquarters of many of the largest of the Companies, has started the fight against the order, and it is aided by the National Independent Telephone Association and the Ohio State Telephone Association. A personal appeal has been made to President Roosevelt, who has promised to make an investigation. Senator Hanna has been appealed to by capitalists interested in the independent companies, many of whom are his warmest friends. Congressmen, too, have been interested, and the question is certain to be entangled with politics. The president of the Cuyahoga Company, the independent telephone exchange system of Cleveland, has declined to remove his telephones, saying that he will make a fight and trust to the courts for his money."

ELECTRIC PUMPING EQUIPMENTS FOR PITTSBURG.—The Westinghouse Electric & Manufacturing Company has placed a contract with the International Steam Pump Company for seven Deane single power well heads and artesian pump barrels which are to be used for pumping water from driven wells at their plant at East Pittsburg. The well heads are to be furnished with motor bases and double reduction gears for direct connections to Westinghouse motors of 5-hp capacity, each operating at 700 r.p.m. The heads will operate at 30 r.p.m. and the pumps will deliver water against a maximum water pressure of 125 pounds. One of the reasons for installing this system is the great prevalence of typhoid fever in the Pittsburg district. The town of East Pittsburg is provided with water works, but the supply is taken from a neighboring river open to contamination. However, in all the district it is found that by drilling down through a few strata of rock a water supply of absolute purity can be secured, and it has been proposed that ultimately the whole city of Pittsburg shall be supplied with water by this method.

SHANGHAI TROLLEY CONTRACT.—A cable dispatch from London of January 13 says: "The Shanghai correspondent of the *Times*, in a dispatch, illustrates the decadence of British commercial prestige in China by citing the action of two British electric companies with reference to a tramway contract in Shanghai. These companies have abandoned their contract, alleging the impossibility of raising the necessary capital, owing to the uncertainty of the political outlook. Their action, the correspondent says, emphasizes the crisicism recently directed against the methods of British financiers in the Far East."

OTTO GAS ENGINE WORKS.—The stockholders of the Otto Gas Engine Works have decided to increase the capital of the corporation from $600,000 to $2,500,000 and build a large, new plant just as soon as the management can find a suitable site for the purpose. Large gas engines, producer gas plants, launches and marine engines, gasoline hoists, compressors and other adaptations of the gas engine will be built promptly at the new plant. A suitable site must contain not less than thirty acres, located on a good water front, with good railroad facilities.

THE AUTOMOBILE TRADE CLUB was organized at a meeting held at the Hotel Navarre, New York City, on Jan. 11, with officers as follows: President, A. D. P. Smith, of Smith & Mabley; vice-president, E. T. Birdsall, of the Standard Automobile Company; secretary, E. B. Gallaher, of the New York Garage Company; treasurer, John E. Plummer. The headquarters of the organization will be at the Hotel Navarre, where a suite of rooms has been engaged.

TELPHERAGE MACHINERY TO COAL JAPANESE WARSHIPS.—The United Telpherage Company, 20-22 Broad Street, New York, has secured a contract by cable from the Japanese Government for telpherage machinery to be used for coaling warships. The company expects to close two further contracts with the same government within the next few days. The machinery will be manufactured at the company's plant at Westfield, N. J.

THIRD RAIL ON LEHIGH VALLEY.—It is stated on excellent authority that the Lehigh Valley Railroad Company is planning the purchase of the Binghamton & Southern Railroad for the purpose of running it as a third-rail electric railway between Dushore, Pa., and Binghamton. It is also said that the Lehigh Company will equip its branch from Harvey's Lake to Wilkesbarre with the third-rail system.

TRUMBULL SPECIALTIES FOR CHILI.—The Trumbull Electric Company, of Plainville, N. Y., through its New York representative, J. D. Watson, has lately secured a substantial contract for its electrical specialties—rosettes and switches, principally—from J. K. Robinson, of Iquique, Chili, who looks after the Westinghouse interests throughout Chili, Peru, Bolivia and Ecuador.

LIGHTING ENGINES FOR NEW FEDERAL SUGAR PLANT.—The Federal Sugar Company has just let a contract for the lighting engines to be installed in its new plant at Yonkers, N. Y. The American Engine Company, of Bound Brook, N. J., secured the contract, which calls for three engines of 120-hp capacity each, to be direct-connected to 75-kw dynamos.

MEXICAN HYDRAULIC PROJECT.—A hydraulic plant is to be constructed on the Jamapa river near Cordoba, Mexico, for general power purposes in that vicinity. Theodore Vanden Peereboom, an ex-officer of the Belgian Army, also Francisco Louvrier and Renato Jonat—both engineers in Mexico city—are primarily interested in the scheme.

ST. LOUIS FAIR.—The Intramural Railway at the World's Fair is completed. The formal driving of the last spike, and the passage of the first electric train over the road will soon be appropriately celebrated. The boilers, which will form part of the battery for power and light used in the operation of the road, have been installed.

MEXICAN POWER & LIGHTING PROJECT.—An extensive electrically operated flour milling plant is to be built at Texcoco, Mexico, by Jose de la Horga. A waterfall will be utilized for supplying the necessary power and for lighting the town. The hydraulic plant will be located about four miles from Tecoco.

BIG TELEPHONE SYSTEMS.—New York City is no longer alone in having over 100,000 telephone subscribers. The Chicago Telephone Company gained 1617 in December, 22,124 in the year, and began January with 101,187.

EQUIPMENT FOR LONDON PRINTING PLANTS.—Kohler Brothers, of Chicago, Ill., have recently taken some fair-sized orders for the electrical equipment of printing presses in London.

General News.

THE TELEPHONE.

ATKINSON, ILL.—The capital stock of the Henry County Telephone Company has been increased from $2500 to $15,000.

FAIRFIELD, ILL.—The Egyptian Telephone & Improvement Company has been incorporated; capital, $2500; to operate telephone, electric light and heating systems. Incorporators: C. M. Brock, Luke Whitson, John H. Morlan.

SLOAN, IA.—The Lawton Telephone Company has been organized here. J. A. Smith is president; A. Boline, vice-president; Dr. C. M. Wray, secretary.

DUBUQUE, IA.—The Iowa Telephone Company will erect a modern telephone exchange building and rebuild the local exchange at a cost of $140,000.

LAKE MILLS, IA.—The Silver Lake & Briston Telephone Company, of Worth County, has filed articles of incorporation with $5000 capital. O. T. Groe, of Lake Mills, is president.

TOPEKA, KAN.—The Carbondale Telephone Company, of Carbondale, has been incorporated. Capital, $2000.

FRANKFORT, KY.—The Tichenor & Hall Telephone Company, of Nelson County, has been incorporated with a capital of $50.

IONIA, MICH.—The Allen Mutual Telephone Company has been incorporated with a capital of $4500.

ESCANABA, MICH.—The Finch Telephone Exchange, of Escanaba, will extend its line to Cedar River this year.

AUSTIN, MINN.—The Tri-State Telephone Company will build a line from Austin to Dexter.

NEW YORK, N. Y.—The Independent Telephone Clearing Association, of New York, capitalized at $5000, has been incorporated. Directors: F. M. Randall, W. H. Homewood and H. H. Corbett.

NEW YORK, N. Y.—Fire on the eighth floor of the main telephone exchange at 81 Willoughby Street, Brooklyn, a few days ago, caused damage to the extent of about $5000. The 150 operators filed out of the office in good order, without any mishaps. The fire drill is practiced in this office. The fire was quenched by the use of sand by the male employees, and communication was soon established.

WINSTON-SALEM, N. C.—It is officially announced that the Bell Telephone Company has secured full control of the field at Winston-Salem, absorbing the Interstate Company. The plant of the Interstate Company at Goldsboro, N. C., is also absorbed by the Bell Company. It is further announced that the Bell Company will extend its lines through the eastern part of the state, making many new connections. The Bell Company has absorbed the entire Interstate Company's system in North Carolina except the exchange at Durham, N. C.

CHARLOTTE, N. C.—The Capital City Telephone Company has been organized in Raleigh. W. T. Gentry, of the Bell Telephone Company, of Atlanta, was elected president; L. A. Carr, of the Interstate Company, of Durham, vice-president; D. I. Carson, George Watts, Hunt Chipley, Julian S. Carr are directors. The Bell Company has taken control of the Interstate Company at all places save Durham. It also controls the Home Telephone Company, of Raleigh. Raleigh and Charlotte will have the only independent exchanges. The new Capitol City Company has been chartered for the purpose of consolidating the various telephone companies in this state.

ELYRIA, OHIO.—The Elyria Telephone Company has increased its capitalization from $50,000 to $100,000 and is preparing to make extensive improvements.

JEFFERSON, OHIO.—The Rock Creek Local Telephone Company was organized here by the adoption of a constitution and election of officers. W. W. Weiss is president.

LIMA, OHIO.—Leading stockholders of the Lima Telephone & Telegraph Company have agreed to purchase the interests of the Federal Telephone Company in the company.

MINERAL RIDGE, OHIO.—The Central District & Printing Telegraph Company (Bell) is putting up new cable and practically rebuilding its exchange at Mineral Ridge.

CLEVELAND, OHIO.—The entire issue of the preferred stock of the United States Telephone Company has been pooled and option on it given to Claude Ashbrook, of Cincinnati, which expires April 1.

NORWOOD, OHIO.—The Norwood Citizens' Telephone Company, capital stock $10,000, has been incorporated by P. H. Shorthall, F. Fangman, C. M. Jones, J. J. Cushing and others. They will build a local exchange.

TOLEDO, OHIO.—The council has appointed a committee to examine the books of the Toledo Home Telephone Company in order to determine the justice of the company's claim that its present rates are too small to be profitable.

LORAIN, OHIO.—Mayor King has vetoed the ordinance passed by the council granting a franchise to the Ohio Telephone & Telegraph Company which is said to be controlled by the Bell Company. The mayor claimed the independent service was satisfactory and sufficient.

TOLEDO, OHIO.—The Empire Electric Company, capital $20,000, has been incorporated by C. E. Sumner, Charles Hartman, W. M. Godfrey, Robert Tucker, F. F. Graves and others. The Company is engaged in installing a telephone plant at San Diego and other cities on the Pacific Coast.

BRILLIANT, OHIO.—The Ohio Valley Telegraph & Telephone Company has been incorporated with $20,000 capital stock by J. G. Gilchrist, Robert Carpenter, C. J. Waddle, J. L. Cox and others. It will build a system connecting Steubenville, New Alexandria and other towns with the extensive coal fields in that district.

TOLEDO, OHIO.—The United States Telephone Company is preparing to string several new long distance lines between Cleveland and Toledo and is building a line west from Toledo to South Bend, Ind., which will give connection with the new Chicago company, thus affording through service from Buffalo to Chicago and all intermediate points.

CLEVELAND, OHIO.—President Dickson, of the Cuyahoga Telephone Company proposes to make radical changes in the charges made for certain classes of service and to do this, careful estimates are being made as to the cost of many items that enter into the charges made for telephone service. Mr. Dickson thinks that a charge of $10 is too much for placing an extra name in the telephone directory and he also considers $10 too much of an extra charge of a desk extension telephone. On the other hand he sees no reason why the company should change the location of a telephone free of charge. Mr. Dickson denies that present contracts are to be abrogated.

RIPLEY, OKLA.—The Ripley Automatic Telephone Company has been incorporated with a capital stock of $15,000. Directors: J. W. Butcher and others.

READING, PA.—The Consolidated Telephone Company is extending its lines to Eastern Berks.

KUTZTOWN, PA.—The Consolidated Telephone Company will extend its lines from here to Lenhartsville.

PITTSBURG, PA.—The Montour Telephone Company has been incorporated with a capital stock of $10,000. Directors: W. B. Woford and others.

BEAVER, PA.—A charter has been recorded here incorporating the Beaver Valley Telephone Company with the following directors: John M. Buchanan, Agnew Hice and Robert W. Darragh, of Beaver; John H. Miller, James G. Mitchell and Henry M. Camp, of Rochester; John Reeves, Dr. J. S. Louthan and Frank F. Brierly, of Beaver Falls; F. G. Barker, F. W. Walker, J. F. Mitchell and R. D. Hunter, of New Brighton; Edward J. Bischoffberger, of Freedom, and Paulus E. Koehler, of Monaca. The line will connect the following towns: Eastvale, Beaver Falls, Patterson Heights, College Hill, Homewood, Ellwood City, Rock Point, Bridgewater, Beaver, Vanport, Industry, Smiths Ferry Georgetown, Hookstown, Rochester, Monaca, Freedom, Baden, Economy and Ambridge.

HURON, S. D.—A franchise for another telephone company has been asked by Messrs. Goecke, of Sioux Falls, and Wisard, of Howard. Metallic circuits with underground wires in the business portion of the city are proposed.

CENTREVILLE, TENN.—A new telephone company is being organized here, to be known as the Citizens' Telephone Company.

SOMERSET, TEX.—The Somerset & San Antonio Telephone Company has been chartered with a capital stock of $3000. The incorporators are W. Caruthers, J. W. Briggs, J. B. McLaughlin, August L. Ernest, W. R. Caruthers and J. N. Dixon.

SAN ANTONIO, TEX.—A switchboard of 2299 capacity, of Stromberg-Carlson make, is in service here by the San Antonio Telephone Company, which has 2200 subscribers. Superintendent A. L. Beze informs us that "by increasing the capacity of the switchboard and doing some outside construction, the number of telephones could be nearly doubled in one year. San Antonio, with a population of 60,000, covers an area of 36 square miles which would make a plant to properly cover the entire city a little expensive, but would prove a paying investment."

WINCHESTER, VA.—The Southern Bell Telephone Company has applied for a franchise in Winchester and a strong fight is expected before the matter is settled.

RICHMOND, VA.—The Laurel Fork Telephone Company, of Carroll County, Va., has been chartered with a capital stock of $5000 by G. W. Alderman, president, and others.

HAMPTON ROADS, VA.—The War Department has forbidden the Hampton Roads Railway & Electric Company from entering the reservation of Old Point, Va., the time having elapsed in which the privilege held good. The company is at present in the hands of a receiver.

WASHBURN, WIS.—The Bayfield County Telephone Company is extending its lines to Bayfield and Houghton.

ABBOTSFORD, WIS.—The Abbotsford Electric Light & Telephone Company has been incorporated with a capital stock of $25,000. Directors: E. C. Schilling, J. Young and others.

LA CROSSE, WIS.—The La Crosse Interurban Telephone Company has been incorporated with a capital stock of $50,000. Directors: W. T. Burford, C. H. Schweizer and others. This is a consolidation of the La Crosse & Southeastern and La Crosse County Telephone Companies.

CRIVITZ, WIS.—The Wisconsin Telephone Company has offered the Wausaukee Independent Telephone Company $5600 for its 50-mile toll line which connects the towns of Wausaukee, Pound, Beaver, Coleman and Marinette. It is said the Wisconsin Company will parallel the lines in the case of a refusal to sell.

TEPEACA, MEX.—Strong inducements are being offered by the jefe politico of this place to any responsible company that will undertake the establishment of a system of telephones in this district.

CHARLOTTETOWN, P. E. I.—The Telephone Company of Prince Edward Island, Ltd., was incorporated in 1885, and covers the most thickly settled piece of country in Canada. It is remarkable for the immense proportion of long distance toll offices and line to local exchange subscribers. Ninety toll offices, all long-distance lines, are grounded, and the McClure system is used in the two largest exchanges. The company contemplates entirely remodelling its system and bringing it up to date. This has already commenced, and it is thought a larger volume of business will result. There is no telephone communication with the mainland. Some of the improvements projected by this company are: new line poles and metallic circuit to Summerside (45 miles); 10 miles new long-distance line; long-distance toll offices equipment: and a new distributing rack, pole line, and increased cable capacity in Charlottetown.

Electric Light and Power.

GADSDEN, ALA.—The new power plant of the Alabama Steel & Wire Company, at the steel plant, has been completed and the electric cars are now being operated by power generated at the new plant. The old plant, formerly used for the car line and lights combined will now be used for the city electric light power.

ATLANTA, GA.—Under the new contract entered into in April this city now has 821 arc lamps at $75 each, or a total of $61,575; 446 series lamps at $33.75 each, or a total of $15,052.50 per year, making a grand total of 1267 at a total cost per year of $76,627.50, or a saving of $7.50 per arc lamp over the price paid the previous year.

BOISE, IDA.—A company which has in view the utilization of the power of Shoshone, Auger and Twin Falls on the Snake River will be organized in the near future under the laws of Maine. The plant will have a capacity of 100,000 horse power and the purpose is to distribute the electrical energy in Idaho, Nevada and Utah. A fall of 430 feet can be obtained from the three falls within a distance of ten miles. The company has already completed a tunnel at Shoshone with a capacity of 20,000 horse power. Dr. A. C. Conrad, I. B. Perrine and F. C. Rutan have been quietly working on the project here. If the present plans are carried out the cost of the plant will be in the neighborhood of $750,000.

JACKSON, KY.—The local lighting plant has been closed. A number of the largest creditors have applied for a receiver for the company. Lewis Enrich, the manager of the company, recently tried to sell his holdings to the Jackson Development Company, but was unsuccessful.

JACKSON, MICH.—There is some talk of constructing a municipal electric light plant.

NEGAUNEE, MICH.—The Council has voted to expend $15,000 for improving the electric light plant.

SCHOOLCRAFT, MICH.—Schoolcraft's municipal lighting plant, built at a cost of $16,000, was started for the first time on city lighting on Christmas day. The plant, which is run by a 125-hp steam engine, furnishes twenty-seven arc lights for the streets and has a capacity of 1500 incandescent lamps for commercial lighting.

WAVERLY, MINN.—Bids will be received Jan. 16 by the Village Council for $8000 electric light plant and water works bonds. Edw. J. Giblin is Village Recorder.

COLUMBIA, MO.—The Mayor writes that the plant of the Columbia Water & Light Company is being appraised with a view to selling the same to the city.

ST. CHARLES, MO.—The directors of the St. Charles Light & Fuel Company have decided to increase the capital stock of the company from $20,000 to $30,000.

WARRENSBURG, MO.—The City Council has authorized the City Attorney to draft an ordinance submitting the question of public ownership of an electric light plant to a vote of the citizens.

PALMYRA, MO.—The Palmyra Light & Water Company, owned by B. F. Hobert, has been sold to W. E. McCully, of Macon, Mo., State Railroad Commissioner. At a recent election the city voted down a proposition to buy the plant for $25,000, and it is presumed these are about the figures paid by Mr. McCully.

JOPLIN, MO.—W. G. Sergeant, of this city, has concluded the deal for the transfer of the water rights of Spring River at Baxter Springs, Kan. The syndicate represented by Mr. Sergeant, composed of Joplin capitalists, paid $2250 for the Baxter water rights, including the dam, mill wheels and all rights on Spring River owned by the town. The syndicate has also purchased the Boston mills, and is now dealing for the water rights at Lowell. The scheme is of vast proportion. Spring River is to be dammed and the entire Joplin mining district is to be furnished with electric power, and other industries will also receive their power from the same source. The power house is to be built at Lowell, just over the border in Kansas, and the work of developing the system will begin in the spring.

IRVINGTON, N. J.—The Town Council has authorized the Fire and Water Committee to secure estimates on the probable cost of an electric light plant.

PLAINFIELD, N. J.—The Public Service Corporation has leased the Union, Somerset and Middlesex Lighting Company, which includes the Plainfield Gas & Electric Light Company and plants at Bound Brook, Somerville, New Brunswick, Rahway and Metuchen. These companies were recently consolidated, the capital being $1,500,000, with the power to issue bonds to the amount of $2,750,000.

ALBANY, N. Y.—Saml. C. Wooster and Walter E. Ward, of this city, are reported interested in the construction of an electric light plant in the west end.

AKRON, N. Y.—The citizens have voted to issue $10,000 bonds for an electric light plant.

CLIFTON SPRINGS, N. Y.—This village is considering the construction of an electric light plant.

NEW YORK, N. Y.—The Triumph Light Company, of Brooklyn, capital $50,000, has been incorporated. The directors are J. H. Roth, H. F. Ashury and John Hoffmann, of Brooklyn.

PORT HENRY, N. Y.—D. F. Payne, of Wadhams Mills, N. Y., is reported to be negotiating with Port Henry people for the installing of electric lights, power to be transmitted from Wadham's Mills.

BOONVILLE, N. Y.—In October, 1901, the people of this village voted in favor of a proposition to raise $45,000 for the erection of a plant to furnish electricity for lighting. The plant was started in operation on Christmas day. The plant is located on the Black River about four and a half miles north of Boonville. The dam across the river is 300 feet long and 22 feet high.

QUEENSBURY, N. Y.—To develop the power resources of the fall of Upper Hudson and to distribute electric power as far west as Utica and Syracuse and as far south as Hudson, the Hudson River Electric Power Company, of Queensbury, with a capital of $1,000,000 has been incorporated here. Directors: E. J. West, Bryce E. Morrow and L. W. Guernsey, all of Glens Falls.

CHEROKEE, N. C.—Bids will be received Jan. 21 by W. A. Jones, Commissioner of Indian Affairs, Department of Interior, Washington, D. C., for furnishing material and constructing an electric light system at the Cherokee school.

ATTICA, OHIO.—The citizens have voted to issue $6250 bonds for an electric light plant.

CADIZ, OHIO.—The Cadiz Electric Light & Power Company has increased its capital from $10,000 to $20,000. Wm. T. Wood is president.

COURTLAND, OHIO.—The question of installing an electric lighting plant is being discussed by local people and the council will be asked to issue $6000 in bonds for the purpose.

XENIA, OHIO.—The Peoples' Gas & Electric Light Company has been fined for contempt of court. The company has been having a controversy over the use of non-insulated wires and recently refused to furnish the city with light, although under contract to do so. A mandatory order to furnish lights issued by the circuit court was ignored, and this resulted in contempt proceedings.

CLEVELAND, OHIO.—The Cleveland Board of Public Service has decided not to accept the schedule of prices proposed in the recent ordinance to compel the Cleveland Electric Illuminating Company to reduce its rates, but it has been decided that a committee of three arbitrators should be appointed to settle on an equitable rate to be charged for electricity. The city will appoint one man, the electric light company another, and the two thus chosen shall select a third.

WILKESBARRE, PA.—The Ashley Electric Light Company has petitioned Council for a franchise to furnish Wilkesbarre with light.

LEBANON, PA.—The Edison Electric Illuminating Company is improving the street lighting system of the city at a cost of $33,000. The old arc lamps are being replaced with new and larger ones.

HOLLIDAYSBURG, PA.—The following officers of the Hollidaysburg Electric Light & Power Company have been elected: President, James W. Gromiller; vice-president, W. H. Markland; secretary and treasurer, John W. Cliber; superintendent, W. A. Frank.

HARRISBURG, PA.—The following-named companies have filed incorporation papers recently: The Fair Chance Electric Company, Pittsburg; capital, $5000; Dunbar Electric Company, of Uniontown; capital, $5000; West Fayette Electric Company, of Uniontown; capital, $5000; North Huntingdon Electric Company, of Greensburg; capital $5000; Hempfield Electric Company, of Greensburg; capital $5000; Bullskin Electric Company, of Uniontown; capital $5000; The East Huntingdon Electric Company, of Greensburg; capital $5000; Pittsburg Heat & Power Company, Pittsburg; capital $5000.

NEWTOWN, PA.—The Newtown Electric Street Railway Company has secured the contract for lighting the streets at the following rates: Ten arc lights of 2000-cp each and 30 incandescent lamps of 32-cp, none of the arc lamps to be placed more than 1500 ft. distant from State or Penn Streets, at $1827 per year for 3 years, or $1740 per year for 5 years; the lamps to burn from dusk to dawn every night; each additional incandescent lamp to cost $28; each additional arc lamp to cost $78, but if less than five are added at one time the price to be $90; the incandescent lamps not to be used longer than 600 hours before being replaced, and if they fall below 75 per cent. of their specified candle power to be replaced before the 600 hours have elapsed.

MILLER, S. D.—The City Council has granted to Stephen Pauly a 20-year franchise for the construction and operation of an electric light plant.

FRANKLIN, TENN.—The Council has granted a franchise to Nashville capitalists, represented here by John S. Denton, giving them the privilege of constructing an electric light plant. The company proposes to construct an ice and cold storage plant in connection with the same.

DETROIT, TEX.—The Detroit Electric Light & Power Company has been incorporated with a capital stock of $10,000. The incorporators are W. E. Whitner, W. T. Davis and J. R. Dillahunty, all of Detroit.

AUSTIN, TEX.—An explosion in the city power house recently resulted in the death of one man and wrecked $30,000 worth of machinery, besides damaging other machinery and the power house very badly. The cause of the accident was the breaking of the governor on the fly wheel.

WAXAHACHIE, TEX.—The Waxahachie Gas & Electric Company has been organized here with a capital of $100,000, to install an electric light and power plant and a gas plant. Incorporators: J. F. Strickland and M. B. Templeton, of Waxahachie; R. C. Vickery, of Ft. Worth, and others.

SALT LAKE CITY, UTAH.—The Utah Light & Power Company has recently increased its electrical supply by establishing a power plant on the Bear River at Garland, Utah. The plant has a capacity of 5000 horse power and is now ready for operation.

CULPEPER, VA.—The Virginia Construction Company, of Richmond, has just completed a new electric light plant at Culpeper for the city and the system has been satisfactorily tested.

FT. MYER, VA.—Bids are wanted Jan. 22 for constructing an electric lighting system at Signal Corps Post, Ft. Myer. Archibald W. Butt, Q. M., U. S. A., can give further information.

NORTH YAKIMA, WASH.—The sale of the Yakima Water, Light & Power Company to Robt. E. Strahorn, of Spokane, is confirmed.

ABBOTTSFORD, WIS.—The Abbottsford Electric Light & Telephone Company has been incorporated with a capital of $25,000.

MILWAUKEE, WIS.—Mayor Rose in his annual message recommends the early construction of the municipal electric light plant.

ENID, OKLA. TER.—The Enid Gas Light, Heat & Power Company, of Enid, has been incorporated with a capital of $150,000 by Lawrence A. Martin and Avery A. Humphrey, both of Guthrie.

The Electric Railway.

MONTGOMERY, ALA.—Negotiations are pending for the consolidation of the Montgomery Traction Company and the Montgomery Street Railway.

AUGUSTA, GA.—A charter has been granted to the Georgia Traction Company to construct an interurban line from Athens to Carnsville, a distance of 33 miles. The capital of the company is $500,000.

ATLANTA, GA.—The electric cars of Atlanta are now under the control of a "train dispatcher" who, by means of a new telephone system just put in, directs the movements of the cars of the Georgia Railway & Electric Company. There are thirty telephones located at various parts of the city.

CHICAGO, ILL.—The proposed plan of reorganization of the Calumet Electric Street Railway by the certificate-holders of the National Bank of Illinois has been definitely abandoned.

CANTON, ILL.—At the recent meeting of the stockholders of the Illinois Central Railway Company, officers were elected as follows: U. G. Orendorff, of Canton, president; W. O. Dean, of Evanston, first vice-president; R. F. Henkle, of Canton, second vice-president; James A. Lawrence, of Chicago, third vice-president; W. D. Plattenburg, of Canton, secretary; E. A. Heald, of Canton, treasurer. Attorney F. A. Dolph was empowered to make the necessary legal arrangements with the Cleveland Trust Company, after which, at the call of the president, another meeting will be held, at which the purchasing and construction committees will be appointed.

DANVILLE, IND.—The right of way between this city and Cartersburg has been purchased by the Indianapolis & Danville Traction Company, and the road will be built connecting with the main line at Plainfield.

COLUMBUS, IND.—The Indiana Central Electric Railway Company has applied for a fifty-year franchise to enter Columbus. The company proposes to build an electric railway from Columbus to West Baden by way of Seymour.

COVINGTON, IND.—The Fountain-Warren Traction Company, promoted two years ago to build a road from Covington to Danville, has made arrangements to begin construction work immediately. The contract has been let to a New York Construction Company.

CHEROKEE, IA.—The Cherokee Electric Lighting Company is considering plans for the construction of an electric railway between Cherokee and the State Hospital for the Insane, which is located about a mile distant from the city. Seventy-five thousand dollars worth of bonds will be floated to cover the expenses of construction and equipment. The power will be furnished by the present power plant of the company.

MADISONVILLE, KY.—The Madisonville Traction Company will build a 12-mile extension from Madisonville to Nortonville. J. M. Huffaker is president of the company.

OWINGSVILLE, KY.—Henry L. Martin, representing Cleveland and Cincinnati people, has right of way and franchises for an electric road from Hillsboro to Salt Lake, Ky.

LEXINGTON, KY.—A suit for the appointment of a receiver and sale of the property of the Blue Grass Consolidated Traction Company has been filed in the Circuit Court at Lexington by B. F. McDonald and twenty-eight other lien holders.

SUMMIT, LA.—Dr. H. K. Butler and several other prominent citizens have acquired the charter for an electric railway from Summit to Magnolia, and will shortly put forth efforts to secure the necessary capital to build and equip the line.

AUGUSTA, ME.—The Railway & Electric Equipment Company, capital $1,000,000, has been organized to sell cars and locomotives for steam and electric railways. Elwood C. Jackson, of Philadelphia; Charles C. Rolston, Chicago, and Frank J. Lewis, Cleveland, are among the incorporators.

PITTSFIELD, MASS.—A petition will be made to the Massachusetts Legislature for an act to incorporate the Berkshire Northern Street Railway Company, the object of which is to operate electric railway lines in North Adams, Williamstown and Cheshire, as a part of a system which is planned to connect the Berkshires with Troy, N. Y. Attorney P. J. Ashe and C. Q. Richmond, of North Adams, Mass., are interested.

DOWAGIAC, MICH.—The City Council has granted to J. G. McMichael a franchise for the electric railway to run from Benton Harbor through this city

MINNEAPOLIS, MINN.—The Minnesota Power & Trolley Company is seeking permission to use the old right of way from Hopkins to Excelsior for an electric railway. Power will be developed at Elk River, from the Mississippi River.

ST. JOSEPH, MO.—The St. Joseph Railway, Light, Heat & Power Company's new power station at the foot of Felix Street is now in operation. The main railway equipment consists of a 1000-kw generator, direct-connected to a 1000-hp Corliss engine. The main equipment of the lighting department consists of a 1500-kw generator, direct-connected to a steam turbine of 1500-hp. As a reserve the company has installed one 425-kw. and one 250-kw generator which can be used either for lighting or power purposes. Besides this, the company will keep in reserve the entire plant that is now used to furnish power for the street railway system. This is the old plant and will be allowed to remain, but the lighting machinery will be taken out.

HASTINGS, NEB.—The Nebraska Central Electric Railway Company is arranging to extend its lines to Omaha.

NEW YORK, N. Y.—The Aldermen have voted unanimously in favor of the franchise for the extension of the Manhattan Elevated system to Westchester, which had previously been approved by the Rapid Transit Commissioners. The extension is nearly completed, and the company has announced that it will open the line early in the spring.

GLOVERSVILLE, N. Y.—The Fonda, Johnstown & Gloversville Railroad Company has purchased the property of the Adirondack Lakes Traction Company, consisting of the trolley line leading from Gloversville to Mountain Lake, and all the accoutrements, hotels and pavilions at the lake. The road will be run independently of the Fonda, Johnstown and Gloversville system, and John Shanahann has been elected president, Lyman K. Brown, vice-president, and E. H. Stechel, secretary. The road will be placed in first-class condition and many improvements are planned at Mountain Lake. The road, which was built in 1901, suffered a severe blow July 4, 1902, when a collision resulted in fourteen deaths. It opens up a delightful country, and under the new management promises to become a well-known Summer resort.

CLEVELAND, OHIO.—The Cleveland, Painesville & Ashtabula Railway has been formally transferred to the company of that name. Heretofore the road has been operated by the Electric Construction Company, of Cleveland, by which it was built.

TOLEDO, OHIO.—The Lake Erie Traction Company, of Toledo, has been incorporated with $100,000 capital stock by S. P. Douglass, W. H. Drake, W. W. Drake, Geo. M. Bailey and C. B. Metcalf, of Findlay. The company proposes to build an electric railway from Toledo to Columbus.

WEST LEIPSIC, OHIO.—The Toledo, Columbus & Cincinnati Electric Railway Company has applied for a franchise in the village. It is stated that practically all the required right of way has been obtained and that contracts for the construction of the road will be placed in the near future. Ellis Bartholomew, of Toledo, is president of the company.

CORTLAND, OHIO.—C. G. Phillips, promoter of the Kenilworth-Warren line, which, it is claimed, has been financed and will be built by the people interested in the Cleveland & Sharon Traction Company, is now projecting a line from Kenilworth to Jefferson. These lines would give both Warren and Jefferson direct connection with Cleveland. Preliminary engineering work for the Kenilworth-Warren line is now in progress.

MECHANICSBURG, PA.—The directors of the Star Trolley Company have decided to order at once all necessary supplies for the early completion of the line.

WILKESBARRE, PA.—The Wilkesbarre & Wyoming Valley Traction Company has signed a contract for new equipment for the South Wilkesbarre power house.

WARREN, PA.—It has been decided to extend the Warren-Jamestown Electric Railway from Frewsburg southward, instead of following the route previously planned.

DONORA, PA.—The Douglass & Donora Street Railway Company, capital $18,000, has been chartered to build a 3-mile line connecting these two Allegheny County points.

NANTICOKE, PA.—Councils have killed the ordinance granting the Nanticoke & Hanover Street Railway Company a franchise, and passed on two readings the ordinance granting a franchise to the People's Street Railway Company, covering practically the same territory.

ALTOONA, PA.—Philadelphia capitalists are interested in a project to build an electric trolley line from Altoona to Bedford, Pa. Power for operating the road will be furnished by the Bedford Water Power & Electric Company, in which City Engineer Harvey Linton, of Altoona, is interested, owning all the water rights.

WILKESBARRE, PA.—At a meeting of the directors of the Hazleton, Weatherly & Mauch Chunk Traction Company, R. F. Loper & Company, of Philadelphia, were awarded the entire issue of $1,000,000 in bonds. The firm will act as fiscal agent of the company, and is to finance and build the line from Hazleton to Mauch Chunk. This road is an important link, connecting the electric railway system from Scranton to Philadelphia.

COLUMBIA, S. C.—The Columbia Electric Street Railway, Light & Power Company, will, it is reported, make extensive improvements. E. B. Clark is general manager.

KNOXVILLE, TENN.—The Knoxville Traction Company has been granted a franchise to build extensive additions to the present lines in the city.

CHATTANOOGA, TENN.—The Chattanooga Electric Railway will issue 30-year 5 per cent bonds to improve the system and build additions to the lines now in operation.

FREDERICKSBURG, TEX.—A company with a capital stock of $300,000 is being organized to undertake the construction of an electric railway from Fredericksburg to Waring, a distance of 25 miles. Among those interested is Alfred Vander Stucken.

GREAT BRIDGE, VA.—An electric railway from Money Point to Great Bridge is being worked up. The line will be six miles long. A connection with Norfolk will likely be made. It is said that the Buell interests are backing the scheme.

TORONTO, ONT.—A company of Toronto, Ont., capitalists has a proposition before the city council of St. Catherines, Ont., to construct an electric railway from St. Catherines to Niagara-on-the-Lake, thence along the river road to Queenstown, thence to St. Catherines, making a belt of 28 miles in length, and embracing the richest fruit lands in the district. The town of Niagara will aid the enterprise to the extent of $15,000, and loans from Grantham and St. Catherines aggregating $45,000 will be asked. The road is capitalized at $250,000.

MONTREAL, QUE.—There is every probability of the proposed electric road between Montreal and Ottawa going through. The finances, which have heretofore been a stumbling block to the enterprise, are said to have been satisfactorily arranged. One water power has already been secured and others along the proposed route will also shortly be obtained. The company has a capital of $500,000, and has been granted a subsidy of $128,000 by the Dominion parliament. The road must be commenced within six months and be completed in three years. The head office will be in Montreal, and the board of provisional directors include Edgar McMullen, of Boston, Mass., the president of the company and J. Douglas Wells, of New York, first vice-president.

New Industrial Companies.

THE RAMBLER AUTOMOBILE COMPANY, of Hatboro, Pa, has been incorporated; capital, $5000.

THE PENNSYLVANIA CARBON GRAPHITE COMPANY, of Scranton, Pa., has been incorporated; capital, $15,000.

THE RUSSELL ELECTRIC COMPANY, of New York, has been incorporated; capital, $10,000. Directors: G. W. Russell, Jr., Minnie G. Reddon, and J. H. Taylor, of New York.

THE PORTABLE ELECTRIC SAFETY LIGHT COMPANY, has been incorporated at Jersey City. It will manufacture and deal in electrical machinery and appliances of every kind.

THE PORTABLE ELECTRIC LIGHT COMPANY, of Jersey City, N. J., has been incorporated; capital, $250,000. Incorporators: Duncan L. McLaren, Henry H. Graff and Joseph Du Vivier.

THE ATLANTIC EQUIPMENT COMPANY, of Schenectady, N. Y., has been incorporated to repair and deal in engines; capital, $25,000. Directors: Leigh Best, C. B. Denny and C. E. Patterson, New York.

THE OWNERS' AUTOMOBILE COMPANY has been incorporated at St. Louis, Mo., with a capital stock of $2000, full paid. The shareholders are Horace A. Davis, William C. Woods and George L. Moselle.

THE COMMERCIAL AUTOMOBILE COMPANY, of New York, has been incorporated: capital, $2000. Directors: O. J. Hershmann, New York; Frederick Werner, Brooklyn, and Anderson Price, Rutherford, N. J.

THE CROSELMIRE & ACKOR COMPANY, Newark, N. J., has been incorporated to crush and treat mineral ores; capital, $100,000. Incorporators: Frederick A. Croselmire, William F. Ackor, and Cecil H. MacMahon.

THE GATE CITY MOTOR CAR COMPANY, of Keokuk, Ia., with a capital stock of $10,000, has been incorporated by Jesse E. Baker and Latham H. Ayer, Jr. These with E. Ross Baker, constitute the first board of directors.

THE MACHINERY & ELECTRICAL COMPANY has been incorporated in Los Angeles, Cal., with a capital stock of $250,000. The directors are Hugh T. Duff, W. B. Woodhill, W. F. Gibbs, C. F. Baker and F. C. Armstrong.

THE POWER CITY ELECTRIC & AUTO. STATION, of Rochester, N. Y., has been incorporated to deal in electrical supplies; capital, $6000. Incorporators: E. M. Van Alstyne, A. W. Van Alstyne, G. R. Van Alstyne, all of Rochester, N. Y.

THE WORTHINGTON AUTOMOBILE COMPANY, of New York City, has been incorporated; capital, $200,000. Directors: G. G. Worthington, of Shawnee, Pa.; W. J. P. Moore, of New Britain, Conn., and H. R. Lounsbury, Jr., of New York City.

THE H. R. ASHBROOK COMPANY, of Toledo, O., capital $10,000, has been incorporated by H. R. Ashbrook, E. M. Taylor, U. G. Ashbrook, J. A. Yoder and others, of Toledo. The company will succeed to the business of H. R. Ashbrook who has been engaged in the handling of telephone securities.

Legal.

WATER POWER CONTRACT.—In a case brought up to the Court of Civil Appeals of Texas between the Gonzales Water Power Company and the Citizens Electric Light & Power Company at the same place, a judgment in favor of the plaintiff water power company was reversed. It was held that, under the plaintiff's contract, to continuously furnish defendant the use of a water wheel for power, plaintiff, failing to keep it in good repair and condition as stipulated, thereby preventing operation, is liable for defendant's additional expense of obtaining other power.

TO PAY FOR TAPPING.—The Texas Supreme Court has rendered a decision affirming the judgment of the lower court awarding the Uvalde National Bank of Uvalde, Tex., $1200 damages against the Western Union Telegraph Company for a loss sustained through wire tapping. The money was obtained from the bank by Rief and Fisher, two noted wire tappers, who are now serving sentences in the Missouri penitentiary for a similar practice, committed in that state. Rief played the rôle of a cattle buyer. The Supreme Court holds that the Western Union was guilty of undue negligence in the transmission of the message over its line.

BLADES STARTING BOX PATENT UPHELD.—The Blades patent, No. 418,678, dated Jan. 7, 1890, covering the automatic underload release starting box, has been upheld in a decision by the United States Court of Appeals at Chicago. The patent was held valid in 1897 by Judge Baker of the Circuit Court of Indiana, and since then suit has been brought in another district. Suit was started in 1898 against Harding & Hammer, selling agents for the Chicago Rheostat Company, which was afterwards acquired by the General Incandescent Arc Light Company. A similar suit is now pending at New York City against these companies.

UPHOLDS EIGHT-HOUR LAW.—The constitutionality of the Kansas eight-hour law has been affirmed by the United States Supreme Court. Justice Harlan said, in handing down the opinion of the court, that if the statute is mischievous, the responsibility rests with the legislators and not the courts. The Kansas law was enacted in 1891 and provided that eight hours should constitute a day's work for workmen employed by the state or by any municipality in the state. It also prohibits contractors from requiring laborers engaged on work for the state to perform more than eight hours labor in a day. Both fine and imprisonment are provided for violation of the law. The case decided was that of W. W. Atkins vs. the State of Kansas. Atkins had a contract with the corporation of Kansas City, Kan., for paving and he was charged with requiring a workman to labor ten hours a day. He was prosecuted in the state courts where the decisions were uniformly against him. Atkins appealed from the decision of the state supreme court to the federal supreme court, alleging that the statute is in violation of the first section of the fourteenth amendment to the constitution, in that it denied him the protection of the law and deprived him of his property without due process.

BOARDING STREET CARS.—In the trial of a personal injury action brought in the United States Circuit Court by Henry D. Corliss against the Nassau Electric Railroad Company of Brooklyn, the controversy was whether the car, which it was alleged the plaintiff was attempting to board, was moving or at rest. It was held by the Circuit Court of Appeals, when the case came before it on an appeal from a judgment in favor of the plaintiff, that evidence of a custom of cars to stop at the point where the accident occurred was admissible. The court said, in part, by Judge Coxe: "The plaintiff's right to recover depended solely upon his ability to establish the proposition that the car was at rest when he attempted to board it. The fact that the place was a designated stopping point for all the defendant's cars, and that they all stopped there, was strongly corroborative of the plaintiff's testimony that the car was not moving. Assume, for the purpose of illustration, that the accident had occurred on a steam road—at Tarrytown, for instance, on the Hudson River Railroad. Can there be a doubt that, in answer to defendant's testimony that the train ran through the station at Tarrytown without stopping, the plaintiff would be permitted to show that Tarrytown was one of the scheduled stations for that train, and that it always stopped there? We think not. The plaintiff was not attempting to prove negligence in stopping or not stopping the car, but simply the existence of a rule and custom which required that the car should stop at that point, and that, in accordance with this rule and custom, all the cars of that line did stop."

Educational.

COLUMBIA UNIVERSITY, N. Y.—Prof. G. F. Sever forwards us the following list of investigations now under progress at the university: Determination of hysteresis losses of a condenser; a comparison of methods of induction motor calculation; selenium photometer; tests on direct current elevator equipments; tests on alternating current elevator equipments; development of a new method for the compounding of alternating current systems; design of and shop tests on a unipolar generator; investigation on arc lamp electrodes; test of a variable speed motor; determination of the ratio of the resistances of the feeder and the return systems of trolley lines; electrolysis in relation to sub-surface systems; comparative costs of central station and isolated plant supply; design of a direct reading instrument for the determination of the strength of magnetic fields; development of methods for the determination of magnetic properties of iron and steel; development of a method for overcoming the inductance in high tension alternating current systems of distribution.

Obituary.

MR. T. H. DELANO.—Mr Thomas H. Delano, founder and editor of the trade paper *Tobacco*, of this city, died last week at his residence, in Greenwich, Conn. Mr. Delano was at one time a publisher in the electrical field, where he was then well known. For many years he was the treasurer of the New York Press Club.

MR. L. ELLIOTT, president and controlling owner of the Antigo Electric Light, Power & Heating Company, of Antigo, Wis., died suddenly the night of Jan. 2. Mr. Elliott, in addition to his active interest in the electric light company, was also the manager of the Antigo Telephone Company and treasurer of the Columbia Manufacturing Company.

MR. H. RUDDICK.—Mr. Hamilton Ruddick, a mechanical and electrical, consulting and constructing engineer, died in his apartment in Brooklyn, last week. He was born at St. John, N. B., in 1826. He came to this country as a young man, and has held many positions throughout the East, being one of the first inspectors of hulls appointed by the United States Government to the port of Buffalo.

MR. F. H. CLARK.—Frank Hodges Clark, once private secretary to Gen. Benjamin F. Butler, died at Chicago last week. During twenty-one years he was a paymaster in the United States Navy. Since 1890 Mr. Clark had been an official of the General Electric Company and of the Westinghouse Electric Company at Washington, D. C., and recently was appointed receiver for the Helios-Upton Storage Battery Company. He was widely known and greatly liked in the electrical field.

GEN. C. H. BARNEY.—Gen. C. H. Barney died at his home in Hackensack, N. J., on Jan. 10, of spinal meningitis. He was sixty years of age. He served as Adjutant General of Rhode Island for five years. In Gov. Van Zant's time he was a Commissioner from New Jersey to the New Orleans Exposition. He served through the civil war as Lieutenant in a Northern regiment, and for several years was Superintendent of the New York and New Jersey Telephone Company. He leaves a wife and three adult children. He early recognized the great value of the telephone, superintended the building of the first long distance line between Providence and Boston and afterward took part in the construction and extension of the system in the metropolitan district, now known as the New York & New Jersey Telephone Company. He was associated at various times with the Inter-state Telephone Company of Providence, the Sawyer-Man Electric Company and the New York Telephone Company, was a member of the National Telephone Association and the National Electric Light Associations, and was well known to electrical engineers and managers all over the country. He was at the Columbian Exposition and also at the Atlanta Exposition, as manager of the Electric Launch service on the water-ways, which proved a very popular feature.

PERSONAL.

MR. THOMAS J. JOHNSTON and Mr. George C. Dean, of the patent law firm of Johnston & Dean, are now located in offices at 11 Pine Street, New York City.

MR. W. F. RICHARDSON, formerly assistant manager of the John A. Roebling's Sons Company's branch, at Cleveland, Ohio, has been transferred to the San Francisco headquarters.

PROF. F. B. CROCKER, of the electrical engineering department of Columbia University, New York City, has sailed with Dr. M. I. Pupin for a short winter trip in Mediterranean waters, proposing to be back by the end of February.

MR. ROBERT W. BLACKWELL, head of the firm bearing his name, is again in this country from London, and will be at the Albemarle Hotel, New York City, for a couple of weeks. He arrived by the *Celtic* at the beginning of this week.

MR. EDWARD N. LAKE, formerly with the Western Electric Company and more recently upon the engineering staff of the Chicago Edison Company, has assumed the management of the switchboard department of the J. Lang Electric Company, of Chicago.

MR. E. A. CAROLAN, manager of the London office of the General Electric Company and a director of the British Thomson-Houston Company, Limited, has returned to New York from a trip to the Pacific Coast and Mexico and will leave next week for Europe.

MR. IRVING H. REYNOLDS, who was formerly with the Allis-Chalmers Company and for many years was identified with the design and construction of their engines, has accepted a position with the William Tod Company, of Youngstown, Ohio, as consulting engineer.

MR. W. W. BORMAN, of Robert W. Blackwell & Company, Ltd., London, is now visiting this country. It will be remembered that Mr. Borman carried on the New York house for some time. He has been busy renewing old friendships and acquaintances, and is glad to be over here again.

MR. D. D. TATE, the chief electrician of the Barney & Smith Car Company, Dayton, Ohio, has been in the east lately, and has been busy putting into commission on the Erie Railroad a splendid new parlor car, whose general equipment, inclusive of the lighting, is about the finest known.

HON. CHANDOS S. STANHOPE, president of the Mexico Electric Tramways, Limited, which concern operates some 120 miles of electric traction system in Mexico City, has arrived in New York from a visit to Europe. While here he can be found at the Hotel Albermarle.

MR. FRANCIS J. GREENE, of Detroit, is endeavoring to introduce a system of wireless telegraphy for train signals and has organized the American Engineering Company to handle the business, with a capital stock of $2,500,000. It prints on a tape its signal and opens and closes signal lighting circuits. Wireless apparatus is delicate stuff for such vital purposes.

MR. WILLIAM SCHWANHAUSSER, chief engineer of the International Steam Pump Company, has returned from a two months' trip to Europe, where he went for the purpose of visiting several of the large engineering works in England and on the Continent. Some large contracts are expected to be received shortly as a result of Mr. Schwanhausser's visit abroad.

MR. A. B. SANDERS, who has for a number of years past been connected with the engineers' department of the American Telephone & Telegraph Company, of New York City, and later with the Electric Storage Battery Company, of Philadelphia, has connected himself with John B. Watson, Drexel Bldg., Philadelphia, taking charge of Mr. Watson's electrical department.

MR. HENRY EDMUNDS, of London, who has been visiting this country and has spent several weeks here and in New England with his family, has returned home. He gave attention to several electrical and other matters while here, and left very well pleased with results in general. He has a large circle of friends in this country, dating back to the earliest days of electric lighting.

MR. GEORGE W. DAVENPORT, a well-known "old timer" in the light and power field, and who, since his early Thomson-Houston days, has been deeply interested in the direction and management of electrical properties, has become third vice-president of the Niagara Falls Power Company, that office having been recently created. Mr. Davenport is a valuable acquisition to the staff of that important enterprise.

PROF. A. G. BELL.—A cable dispatch from Genoa of Jan. 7 says: Professor Alexander Graham Bell, of the Smithsonian Institution, at Washington, and Mrs. Bell left here to-day on the North German Lloyd steamship *Prinzessin Irene*, with the body of James Smithson, founder of the institution, who died in Genoa in 1829. The city of Genoa will maintain the monument erected to the memory of James Smithson.

MR. JAMES C. STEWART, of the American contracting firm of James Stewart & Company of St. Louis, Pittsburg and London, is now on a visit to this side. He had supervision of the construction of the Trafford Park, Manchester, plant of the British Westinghouse Company, and has since had charge of the building of the various large power plants for which the company has secured throughout Great Britain.

MR. G. COLLINS.—George Collins, author of "A Strange Railroad Wreck," bearing the imprint of The Broadway Publishing Company, is, says the *New York Times*, an almost helpless cripple. He is employed in a telegraph office in Pittsburg. He is said to be a fine linguist, an expert stenographer and telegrapher, and to know all the details of printing and book publishing. His story is authentic, for he is said to know the characters personally.

MR. JAMES H. ROSENTHAL, manager of the British end of the Babcock & Wilcox Company, is now on a short visit and can be found at the Babcock & Wilcox Companies' export department. While on this side he is expected to place some fair sized orders for separators and other steam plant equipment. Mr. J. F. Alexander, who represents the Babcock & Wilcox people in the West Indies, is also in New York at present. He expects to be here for about 10 days.

MR. SEWARD BABBITT, who for a number of years has been general sales agent for the William Tod Company, of Youngstown, O., has resigned his position to take effect January 1, 1904, and has accepted a position with the De La Vergne Refrigerating Machine Company, of New York City, where he will devote his time to the sale of the Koerting gas engine; the De La Vergne Company having secured the right for the exclusive manufacture and sale of this engine in this country.

REAR ADMIRAL MELVILLE, ex-chief of the bureau of steam navigation, U. S. Navy, has consented to act as engineer-in-chief of the Audit & Appraisement Company of America. Admiral Melville has a national reputation as consulting engineer in all branches of engineering science, and his connection with the Auditing & Appraisement Company of America is an assurance that its examinations and reports will be of the highest order. He has returned recently from a trip to Mexico, where he was engaged in making an inspection of some of the properties of the United Mining & Development Company of America.

Trade Notes.

ELECTRIC STORAGE BATTERY COMPANY has removed its sales office from the Nevada Block, San Francisco, to the Rialto Building, corner of New Montgomery and Mission Streets.

NEW ENGLAND ELECTRICAL WORKS, Lisbon, N. H., Goldmark & Wallace, general agents, New York, have issued a striking calendar in yellow, red and green, broad sheet size, for 1904, with month pads.

THE GORGEOUS CALENDAR of the year is that put out with the name of the National Electric Company, of Milwaukee. It is a reproduction in colors of a painting by Asti and is a splendid piece of work. The effect of the picture is heightened by the method adopted of framing.

STERLING ELECTRIC COMPANY, of Lafayette, Ind., has just put forth a new catalogue illustrating its new lamp signal magneto switchboard. This board is a fine example of the further development in telephone practice and the pamphlet brings out a number of its essential and leading features. The booklet can be had for the asking.

THE ELECTRIC APPLIANCE COMPANY, Chicago, calls attention to the "points" in connection with Adams-Bagnall arc lamps. Among the points in a bulletin just issued are: "125,000 lamps in successful operation; no change of model in past five years; 75% of the parts of these lamps are interchangeable; no delay in getting parts 10 years hence; positive value in non-changing model." The complete bulletins will be sent upon request.

THE NATIONAL GAS ENGINE, manufactured for the Savage & Love Company, Rockford, Ill., is one that has been put to a very severe test as to uniformity of speed where the variation of the load has run between wide limits. The machine has answered every requirement and has proven decidedly popular for belted or direct connection to dynamos in isolated plants and for use in machine shops. One good feature of the machine is the interchangeability, whereby any part may be changed at any time should the machine become damaged in any way.

THE J. LANG ELECTRIC COMPANY announces that it has secured the services of Mr. Edward N. Lake, formerly chief switchboard draughtsman of the Western Electric Company, and more recently upon the Chicago Edison Company's engineering staff, who will assume the management of its switchboard department. It states that it will be pleased to furnish designs and estimates upon switchboard equipment for any system of generation and transmission. The usual prompt and cheerful attention will be paid to all orders, whether for the smallest tablet boards or the largest switchboards. With its facilities, experience and equipment the concern feels certain it can meet the most rigid requirements upon this class of apparatus in the point of workmanship, finish and in the time of execution.

THE N. S. STORAGE BATTERY COMPANY, LTD.—A new storage battery invented by Mr. J. T. Niblett, the well-known author of a book on the storage battery, is being placed on the market by the N. S. Electric Storage Company, Ltd., which has its headquarters at 139 Queen Victoria Street, London, E. C., and has, we are given to understand, ample backing by gentlemen of considerable means. Mr. Fred J. Down, of Harpenden, Herts, has associated himself with this company in the way of introducing the battery to consumers in Great Britain, where he has a very extensive acquaintance among electrical engineers. Mr. Down will perhaps be best remembered as having been a partner in the firm of Laing, Wharton & Down, and has during the past few years introduced a great many electrical specialties to the notice of electrical engineers in Great Britain.

CINCINNATI AIR AND GAS COMPRESSORS are described in pamphlet L-26-A just issued by the Laidlaw-Dunn-Gordon Company, of 114 Liberty Street, New York City. These machines are of medium and small sizes, the steam ends being equipped with plain slide valves and Meyer valve gears and the air ends with poppet valves. One of the compressors is of an entirely new type in that the air cylinders are provided both with mechanically moved valves and with poppet valves, all points in the compression cycle being determined by the mechanically moved valves, with the exception of the opening of the exhaust, which is determined by the poppet valves. This arrangement combines the positive action, noiseless operation and durability of mechanically moved valves with the elasticity of poppet valves, at the same time avoiding the noise and rapid wear. This pamphlet, which is of convenient pocket size, will be sent upon request to those interested.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED JANUARY 5, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., N. Y.]

748,571. ELECTRIC SOLDERING IRON; James I. Ayer, Cambridgeport, Mass. App. filed Nov. 13, 1902. The tip is of small diameter but given large surface of contact with the heating core by means of a clamp attached to the core and making elongated annular contact with the tip.

748,572. APPARATUS FOR CONTROLLING CURRENT SUPPLY TO ELECTRICALLY HEATED TOOLS; James I. Ayer, Cambridge, Mass. App. filed June 1, 1903. A rheostat on the wall is so connected with a portable tool that when the tool is in use, it gets the full current, but when it is deposited upon a stand, a switch automatically cuts in the rheostat and reduces the current supply.

748,573. ELECTRICALLY HEATED TOOL; James I. Ayer, Cambridge, Mass. App. filed June 15, 1903. The coils of the controlling resistance are thrown into series or parallel as desired for varying the heat.

748,574. APPARATUS FOR PRODUCING ELECTRIC ARCS FOR HEATING AND LIGHTING PURPOSES; James I. Ayer, Cambridge, Mass. App. filed June 22, 1903. The arc is produced between the edges of two disks of carbon, they being rotated slightly to present new surfaces at each operation, by the movement of the disks in a lateral direction to their working position.

748,591. THIRD RAIL COVER; Henry F. Duffy, Seattle, Wash. App. filed June 20, 1903. The sections of a sectional cover are successively raised and lowered by the car to permit the contact shoe to make uninterrupted contact with the rail.

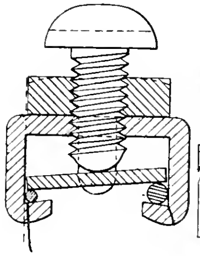
748,592. THIRD RAIL PROTECTOR; Henry F. Duffy, Seattle, Wash. App. filed June 20, 1903. A modification of the preceding patent.

748,597. WIRELESS SIGNALING DEVICE; Lee De Forest, New York, N. Y. App. filed Dec. 24, 1902. The radiated energy is concentrated in the direction desired by the use of a reflector of the waves and of a horizontal directive and concentrating conductor.

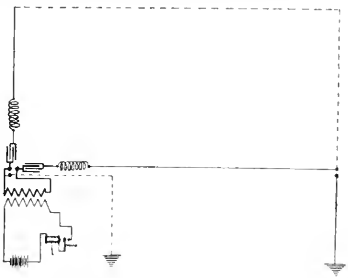
748,599. INCANDESCENT ELECTRIC LAMP SOCKET; Henry A. Framburg, Chicago, Ill. App. filed April 9, 1903. Details.

748,609. PRODUCTION OF HYDROXIDS AND OXIDS OF METALS BY ELECTROLYSIS; Frederick F. Hunt, New Brighton, N. Y. App. filed Jan. 22, 1903. (See page 136.)

748,619. ELECTRIC RAILWAY; Charles J. Kintner, New York, N. Y. App. filed Sept. 22, 1899. The sections of the working conductor are held in a strained and bowed condition by springs acting on rock-shafts connected with their terminals. The contact shoe presses the section downward to connect it with the feeder.



748,716.—Wire Connector.



749,131.—Wireless Signaling Apparatus.

748,620. ELECTRIC RAILWAY; Charles J. Kintner, New York, N. Y. App. filed March 10, 1902. A feature of this invention is the provision of circuit closers which automatically connect and disconnect turn-out third rails when the track switch is thrown.

748,621. SAFETY SYSTEM OF ELECTRIC RAILWAYS; Charles J. Kintner, New York, N. Y. App. filed Nov. 15, 1902. Circuits and circuit connections whereby the current potential is always maintained substantially constant to the motor on the car and each sectional conductor is automatically disconnected from the current feeder only after electrical connection has been severed between it and the current collecting means carried by the car.

748,635. AUTOMATIC BRAKE FOR CONTROLLING SWITCHES OF ELECTRIC MOTORS; Frederick A. Muschenheim and Wm. F. Hendry, New York, N. Y. App. filed June 2, 1902. An electro-magnetic brake in circuit with the motor armature determines the speed of movement of the rheostat arm in accordance with the speed of the motor.

748,638. ELECTRIC CIRCUIT CLOSER AND BREAKER; Thomas H. McQuown, Biggsville, Ill. App. filed Sept. 26, 1902. A contact device for electric clocks.

748,639. FUSE FOR ELECTRIC CIRCUITS; Theodore Nagel, Chicago, Ill. App. filed April 24, 1903. Detail construction of the terminal parts of an inclosed fuse.

748,688. STREET RAILWAY SWITCH; Walter J. Bell, Los Angeles, Cal. App. filed May 7, 1903. Structural features in a switch throwing apparatus operated by hydraulic cylinders controlled by electric valves.

748,690. TELEPHONE TRANSMITTER; Charles F. Bennett, Waterloo, Ia. App. filed Nov. 29, 1901. (See page 136.)

748,716. WIRE CONNECTOR; James S. Ford, Chicago, Ill. App. filed Oct. 9, 1903. A connector by which wires of different sizes may be clamped against two fixed jaws by a single movable paw, the latter consisting of a freely moving plate against the center of which a clamping screw presses.

748,718. EXTENSION LAMP HANGER; Fernando H. Geisler, Dayton, Ohio. App. filed Oct. 5, 1903. A telescoping tube having a ball and socket connection at the ceiling.

748,749. ELECTRICAL SYSTEM OF HEATING; Edward H. Kitfield, Swampscott, Mass. App. filed Oct. 26, 1903. Thermostats switch the heaters into and out of circuit as the temperature of the heated apartment requires.

748,810. ELECTRIC CAR PLOW; William F. Taylor, Jr., Providence, R. I. App. filed March 30, 1903. The plow has a main contact for the propelling current, and subsidiary contacts for engagement with extra rails in signalling circuits.

748,811. SWITCH; William F. Taylor, Jr., Providence, R. I. App. filed March 30, 1903. A track switch moved by motors in the roadbed to which current is delivered from the trolley wire through hinged arms on the car which drag over contact plates in the roadbed.

748,812. SWITCH THROWING MECHANISM; William F. Taylor, Jr., Providence, R. I. App. filed March 30, 1903. A special arrangement of gearing actuated by an electric motor to throw a switch tongue.

748,813. CONTACT SHOE; William F. Taylor, Jr., Providence, R. I. App. filed March 30, 1903. The shoe is suspended by overhead supports to be engaged by a trolley, the invention residing in the details of construction.

748,814. SEMAPHORE MECHANISM; William F. Taylor, Jr., Providence, R. I. App. filed March 30, 1903. A motor which moves a semaphore arm is cut out when the arm moves a switch at the end of its motion.

748,815. RAILWAY BLOCK SIGNAL AND SWITCH; William F. Taylor, Jr., Providence, R. I. App. filed March 30, 1903. Both signals and rail switches are operated by a suitable controller on the car platform.

748,824. BLOCK SIGNAL SYSTEM; Joseph Weatherby, Jr., Wilmington, Del. App. filed July 24, 1902. Details.

748,872. ELECTRIC RAILWAY SYSTEM; Wm. G. Lowrie, New York, N. Y. App. filed June 21, 1901. A trolley moves through a closed conduit in contact with conductors therein, the motion being obtained by the attraction of a magnet carried by the car, the invention relating particularly to the construction of the trolley.

748,904. ELECTRIC ARC LAMP; Luis Wirtz and Thomas Hamilton-Adams, London, England. App. filed Feb. 4, 1903. Details.

748,906. TRANSMITTER; Ernest E. Yaxley, Chicago, Ill. App. filed April 13, 1901. (See page 136.)

748,907. ELECTRIC DYNAMO OR MOTOR WITH ALTERNATING FIELD; Rudolf Ziegenberg, Schoneberg, Berlin, Germany. App. filed April 25, 1903. A double brush on the commutator has its two parts connected through an induction device for producing an electro-motive force equivalent to and opposite in phase, from the electro-motive force generated in the coil which at any moment is short circuited; this to prevent arcing.

748,915. ELECTRIC ARC LAMP; Edward H. Belden, Dayton, Ohio. App. filed April 28, 1902. Carbon lifting means embodying an electro-magnet so disposed with reference to its armature and other connected parts as to counter-balance the latter, so that they may be operated by a weaker magnet than would be necessary under ordinary conditions.

748,940. METHOD OF PRODUCING ELECTRODES FOR STORAGE BATTERIES; Frederick A. Feldkamp, Newark, N. J. App. filed April 17, 1903. (See page 136.)

748,941. ELECTRIC SIGNAL SYSTEM; Howard A. Fessenden, Detroit, Mich. App. filed Dec. 16, 1901. The system comprises transmitters at different stations for a plurality of corresponding signals, an alarm at a receiving station operating continuously, a circuit controlling the alarm extending to the various transmitters and means for respectively closing and opening the circuit whenever the transmitters are in or out of registration with each other.

748,961. ELECTRIC COUPLING; George A. Le Fevre, New York, N. Y. App. filed Jan. 28, 1903. A gang of female socket couplings mounted on a fixed support and a gang of male couplings carried by a movable support and corresponding respectively with the female couplings, whereby a number of circuits may be simultaneously connected up.

748,970. AUTOMATIC SIGNALING APPARATUS; Ira A. Michael, Chicago, Ill. App. filed June 27, 1902. A signal member adapted to be moved in opposite directions is actuated in a given direction by a current impulse of a certain duration; after the direction of motion is determined, a step by step mechanism continues the motion under further pulsations to finish the movement.

748,980. TELEPHONE EXCHANGE; Nils Emel Norstrom, Chicago, Ill. App. filed March 16, 1901. (See page 137.)

748,985. APPARATUS FOR ELECTROLYTIC DECOMPOSITION OF ALKALI CHLORIDES; Johan Jacob Rink, Elsinore, Denmark. App. filed April 4, 1902. (See page 136.)

748,987. TROLLEY HARP; Edward D. Rockwell, Bristol, Conn. App. filed Nov. 7, 1903. The wheel bearings are slid into notches in the harp and the wheel is free to rock to follow curvatures in the wire.

749,016. ELECTRIC ARC LAMP; Edward H. Belden, Fort Wayne, Ind. App. filed April 17, 1901. The humming of an alternating current lamp is prevented by supporting the operating mechanism independently of the casing and cushioning the various parts.

749,017. ELECTRIC ARC LAMP; Edward H. Belden, Fort Wayne, Ind. App. filed Aug. 6, 1900. The sensitiveness of the controlling mechanism is increased by the tendency of the shunt field to neutralize the influence of the series field by reversing the polarity of that portion of the armature which moves in a series field.

749,018. ELECTRIC ARC LAMP; Edward H. Belden, Fort Wayne, Ind. App. filed Aug. 13, 1900. A novel arrangement of series magnet coils and a rocking armature operatively connected with the movable carbon and arranged in the upper portion of the casing.

749,031. TELEGRAPH APPARATUS; Frederick G. Creed, Lenzie, Scotland. App. filed Sept. 3, 1901. The tape perforating punch of the receiver and the tape feeding devices are given a corrective motion at the moment of receiving signals to insure that the perforations in the receiving tape shall be similarly located to those in the transmitting tape.

749,032. PERFORATING TELEGRAPHY; Frederick G. Creed, Lenzie, Scotland. App. filed Aug. 4, 1902. In this receiving apparatus the punches are operated by motors and not by the armatures of electromagnets, the latter being used to control the operation of the motor and punches, any error in the position of the tape is corrected by suitable synchronizing means.

749,033. TELEGRAPHIC RECEIVING APPARATUS; Frederick G. Creed, Lenzie, Scotland. App. filed Aug. 9, 1902. Relates to the system of the two preceding patents.

749,042. ELECTRIC RAILWAY SYSTEM; William M. Eader, Middletown, Md. App. filed July 27, 1903. A collecting device for engaging a third rail, consisting of spring mounted rollers spaced apart and arranged to readily engage a second section of the rail when passing from one section to another.

749,085. ELECTRICAL CUT OUT; Columbus B. McPherson, Birmingham, Ill. App. filed Nov. 14, 1902. Details.

749,105. ELECTRIC SIGNAL; Baptist H. Scott, Allegheny, Pa. App. filed Jan. 20, 1903. Details of an annunciator operated by a motor.

749,111. APPARATUS FOR SIGNALING ON LOCOMOTIVES; Hermann Stadelmann, Jr., Apolda, Germany. App. filed Feb. 21, 1903. Details.

749,131. WIRELESS SIGNALING APPARATUS; Lee De Forest, New York, N. Y. App. filed March 6, 1901. Direction is given to the projected waves by using a vertical and a horizontal conductor in series with the earth which thereby causes the waves to travel in a single plane which includes the two conductors, and to assume a direction corresponding to the position of said conductors.

749,138. ADJUSTABLE ELECTROLIER; George Andersen, Denver, Col. App. filed March 27, 1902. A telescoping stem through which the flexible conductors lead to a coiling up drum and ratchet at the ceiling.

Electrical World and Engineer

CONTENTS.

THE AUTOMOBILE SHOW.

The general interest in automobilism and the magnitude of the new industry are well exemplified in the fine show now being given in this city at Madison Square Garden. In many respects the fourth show far surpasses its predecessors, and there are many indications which go to prove that the interest shown by the public is not fugitive and ephemeral, but deep-seated and permanent. The bicycle now seems to have been a craze, though we cannot personally understand why people have dropped it so generally as a means of exercise; but the automobile appears to meet many human wants and necessities, and we can see no reason why its ability to fill them should not make it a lasting and enormous industrial success. We find encouragement also in the large display of electric vehicles. Out of 250 in the show, nearly 50 are of the electric class, and barely a dozen are steam, while gasoline claims about 175, the others being also gasoline, but of the motor bicycle type. There is nothing in such figures to make electrical engineers despair of the future, especially as a large proportion of the electrics are not of the fancy type, but strictly industrial and utilitarian. A great deal has been said about the inadequacy of the storage battery for such work, but these statistics are more or less of a vindication for it.

GERMAN PROGRESS IN ELECTRIC LIGHTING.

We are wonted to think of our German friends as in the very front rank of technical progress and so, indeed, they are; but the brief abstract of the statistics of central station lighting which was given in the Digest last week is not a little surprising. One would suppose that in an enterprising country of vast technical achievements where both apparatus and labor are far cheaper than with us, the electric lighting industry would have already shown a very complete stage of growth; but a comparison with the admirable data of Census Bulletin 5, dealing with American central stations, shows that the art here has reached at least a far completer stage of exploitation than in Germany. To begin with, there are 3,620 American stations, against 971 German stations, giving nearly twice the number of plants in proportion to the population and nearly four times the absolute number to our credit. This of itself is significant, but it is still more important to note that in spite of the large number of small plants in this country, the output holds fully up to the standard set by numbers. We have over 18,000,000 incandescent lamps connected, as against the 5,000,000 in the German stations, and 385,000 arcs, against their 93,000. In electric power we more than make up any deficit that might show elsewhere, for the American stations have about 620,000 hp connected to central stations, aside from the many private power plants, while Germany shows about 219,000 hp. It is thus evident that the average size of the American stations is not much less, in spite of the difference in density of population. This is borne out by the total capacity of the central station generators in the two countries, the American total being about 1,225,000 kw, the German total 395,000. It is apparent, however, that the many small American plants somewhat more than offset the effect of the very large plants in important centers. Reduced to round figures, the American plants average about 338 kw, the German about 420. We should have anticipated a larger difference.

The upshot of the matter is that in proportion to the population electric lights are used almost twice as freely here as in Germany.

In particular we use arc lights conspicuously more extensively, in which work the small plants take a very important part. As regards the general character of the installations, there are some very notable differences in the practice of the two countries. The German stations, thanks to the general density of the population, adhere far more closely to direct-current machinery than we do here. Five-eighths of the total dynamo capacity in Germany is in direct-current generators, while here five-eighths is in alternating generators, polyphase and other. As a natural result of this preponderance of direct-current working, the German stations use storage batteries far more freely than they are used here, not only relatively, but absolutely. In fact, they employ battery capacity aggregating 87,000 kw, while here the meagre total is barely over 30,000 kw. Likewise, they use gas engines relatively more than we do, 61 stations aggregating 6,378 kw, reporting gas as a motive power, while the American total is 1,218 rated hp in the engines. Moreover, there is a preponderance of German effort in wind power, one station of 220-kw capacity reporting that unique condition. A full report on this curio would make interesting reading. In the use of water power we are at an obvious advantage in the matter of natural resources, and in fact 22.2 per cent. of our total capacity is in water wheels, the German figure being about 15 per cent. As regards the sale of the product, it is noticeable that the Germans use meters far more freely than is the custom here. To be specific, they employ 203,758, while those reported here amount to 582,689. This perhaps is the result again of the many small American stations doing a disproportionate amount of arc lighting, and letting things go on the contract basis. Certainly our large stations have long ago learned the necessity of metered service.

In spite of the relatively smaller use of electric lighting in Germany, the growth of the industry there has been striking. It must be remembered that Germany, with all its splendid standing in the world's work, is not a rich country as regards the mass of its people. It is burdened with militarism and has a vast amount of unproductive capital and worse than unproductive labor devoted to preparations for the discomfiture of possible obtrusive neighbors. Considering this, Germany's progress in the arts of peace is doubly creditable. The growth of central station lighting shows nothing of the tremendous impetus given to American lighting by the introduction of the alternating system; but oddly enough, 1898 was the banner year for construction in both countries. In that year 150 central stations were built in Germany and 277 in the United States. Since then there has been less activity, but the growth in output has certainly been very great. At present in both countries the profitable field is doubtless fairly well covered; but existing plants are growing rapidly. The many undeveloped American water powers give promise of great increase in central stations devoted mainly to power distribution, but neither here nor in Germany can there be expected a rapid increase in the number of lighting stations. As we glance over the German report the impression is brought to us that the German development has been along more conservative lines than our own. It has been there more confined to the larger cities and towns, has had to cover less unproductive territory and has steadily followed the line of least resistance. In some respects it has had to meet severer competition than that encountered here, for Germany is the home of the Welsbach burner, which has made here relatively little impression. A pfennig looks bigger in Germany than a cent does here, and the closer competition has tended to economical practice in station design and operation. But we doubt whether the big German stations show better results than the big stations here, although our small stations might suffer by a comparison.

Wireless.

About once in so often we feel it incumbent upon us to stir up our wireless friends with a sharp stick, and to inquire politely but firmly what they are doing about it. We are not aware that wireless telegraphers have acquired the habit of hibernation, but so little has been heard from them of late that we fear they may be emulating the woodchuck. If so, will they come out temporarily as per schedule on Candlemas day? Possibly the Donnybrook Fair inaugurated at the yacht races, where a dozen or so syntonic culturists indulged in a free extra terrestrial fight, may have left some of the participants in a state of coma; or the language which then belabored the ether—language we understand that would make Dr. Parkhurst turn pale and Anthony Comstock throw a fit—may have shocked some sensitive souls into silence. Be that as it may, it is certain that, for several months little has been heard from the wireless contingent, save the usual nautical dispatches sent when the apparatus happens to be working. We have described a new system or two and will joyfully describe their practical operations when we get a chance. But the great transmissions, conquering sea and land with their well-marshalled etherial battalions seem to be in the state cheerfully referred to by Artemus Ward as non-ester. Really, we should begin to get discouraged were it not for our faith in the useful future of the art and our keen remembrance of the dreary early history of the telephone. That great invention knocked about at least a half a dozen years before it really got anywhere, and wireless telegraphy, for its age, is relatively in better case than the telephone. On the other hand, a great electrical discovery should be far more quickly turned to account now than a quarter century ago. More than anything else, wireless telegraphy needs a careful non-partisan study of working conditions. We understand that the British Post Office is testing very thoroughly various systems and we hope in due time that the results in detail will be given to the public. This is good as far as it goes, but the relation of conditions external to the apparatus to results obtained is a matter of more vital interest, as disclosing the nature of possible limitations, if such exist.

A Method of Photographing Alternating Current Wave Forms.

The adoption of alternating-current machinery for power transmission, due to the convenience and reliability of the alternating-current transformer, has rendered the study of the wave forms of alternating current very necessary. There are particular cases in which a ripple on the back of an alternating-current wave may play a more important part than the fundamental wave to which it belongs. A great variety of devices have been suggested and employed for detecting, or recording, the wave form of alternating currents. Where the waves have ample power, as in power transmission circuits, there are several forms of instruments in practical laboratory use which accomplish this result. Where, however, the current waves have but little power, as in telegraph circuits of earth and wire, or still more, in wireless telegraph circuits of earth and earth, or earth and upper atmosphere, there is no known apparatus, either for indicating, or for recording the wave form. Moreover, in telephone and wireless telegraph circuits the frequency is very high, often far above the frequency of oscillation of material vibrating systems. The periodic time of an oscillograph mirror is often about 100 microseconds, and any wave or ripple to be recorded should, therefore, have a period of at least several hundred microseconds. But a microsecond is a long dreary waste of time to a wireless telegraph wave, and 250 complete waves of wireless alternating current can comfortably find room within a hundred microseconds, from a hundred-foot mast or sending antenna.

Leaving, however, to the tender mercies of future time the care of the short and delicate wave forms in electric communication, the interest of to-day lies in the methods of recording the forms of waves that each occupy many miles of free space for their development. The Blondel oscillograph is a typical apparatus. A tiny mirror is supported on a loop of wire, the loop being held in a very intense magnetic field, and being traversed by the current to be investigated. The natural period of vibration being so short, the loop and mirror deflect at every ripple in the wave, and throw a tiny ray of light upon the surface of a steadily rotating drum, carrying a strip of sensitive kodak film. In order to obtain sufficient photographic action from so small a ray, moving with great speed over the film, the most intense luminous ray of the arc lamp is employed. In the ordinary oscillographic trace, as photographically developed and printed, the scale of time is given by the fundamental wave, which intersects the zero or middle line at definite intervals, the frequency of which is supposed to be known with a suitable degree of accuracy.

In the article appearing on page 169 of this number, Mr. C. J. Spencer describes a particular modification of an oscillograph of his own construction, in which the feature of particular interest lies in the method of marking off the time. It consists in employing an alternating-current arc lamp as the source of light for the reflected protographing ray. This has the advantage that when the wave to be recorded has a relatively long and somewhat uncertain or variable period, as in the secondary member of an induction motor, the time can be reckoned from the dotted photographic line of an alternating-current arc lamp, knowing the frequency of that current; whereas, the full photographic line obtained from a direct-current arc would require separate and additional means of determining the time measure. This device of a dotted photographic line might be very serviceable in some researches on long and variable wave lengths. It seems to have a lessened or doubtful value for short waves of readily measurable and definite lengths. Every device of this character becomes of greater interest as our knowledge of wave forms increases and the pursuit of that knowledge is pushed further afield.

INDUCTION MOTOR DESIGN.

Mr. Hobart's paper on the armature diameter of induction motors is an effective disclosure of some painfully common faults in design. The history of induction motor design is a curious story of the effect of fads and prejudices in forcing design into devious and unpleasant paths. Mr. Hobart, who was in the art almost at the beginning, must have a keen appreciation of this and could doubtless tell many an interesting tale if he were so disposed. In the beginning the induction motor was looked upon with ill-concealed distrust, not to say contempt, by the average electrical man. It came to us here labeled "Made in Germany," backed by the fame of Brown and the sonorous name of Dobrowolsky, and in spite of the earlier work of Tesla in this country, it was looked upon as an ill-omened intruder. The first accusation brought against it was that it gave no starting torque to speak of and hence was inapplicable to all the ordinary cases where direct-current motors could give plenty of torque, although in fact they generally did not need it. Hence, almost the first effort of the designer was to produce an induction motor which would give a powerful starting effort. This was successfully accomplished, and the motors were then grudgingly admitted to be capable of starting, but were alleged to require for that purpose enormous currents, so great as to render the whole class quite impracticable. A little attention to the starting resistance question soon settled this, and with it the accusation of bad power factor. A simple and robust motor had been produced capable of giving a powerful torque at starting without excessive current and of giving both good efficiency and good power factor. In these respects some of the early motors were as good as any of the later types, but they had, as a rule, high rotative speed.

This speed factor, of course, was the point next attacked by the direct-current contingent, and there was at once in every competitive case a cry for motors of abnormally low speed. This had to be met by extreme multipolar motors and then the problem of induction motor design was opened up in its broadest aspects. But even more trouble was in store, for there began to be a cry for small variation of speed with change of load, and as this property unfortunately could be easily obtained the demand was met, to the designer's great annoyance. We say unfortunately, for the result was the common introduction of speed specifications of a kind utterly needless for most practical purposes, and not then or at any time since commercially filled by direct-current machines. And thus the problem of design came up to the point where Mr. Hobart's paper is particularly pertinent. The fault of abnormally large inductance due to needlessly long end connections was a natural result of attempting to produce low-speed motors of moderate size with low armature resistance. In spite of skillful shaping of the teeth and reduction of the air-gap to the lowest possible figures, a good power factor became difficult of attainment, and as Mr. Hobart shows, the end connectors were chargeable with no inconsiderable part of the difficulty, although the fact was unrecognized. The resulting faults were beautifully emphasized in some of the motors produced a few years ago, when, in the struggle for simplicity of manufacture, several sizes of motor were built up from the same size of armature and field punchings. The more powerful machines of such a series were admirable, but as the cores were made shorter and shorter upon the same diameter and pole pitch, the area of the polar air-gap was reduced and the relative length of the end connectors increased, to the utter demoralization of the power factor.

If an induction motor must have low rotative speed the most favorable condition for obtaining it is a reduction of the frequency. If this be impracticable, the number of poles must be increased and then the trouble begins. Other things being equal, a large polar pitch is an advantage and hence the tendency is in the direction of a rather flat motor of rather large diameter. But as Mr. Hobart shows, this modification of proportions soon reaches its limit, since increase in the relative length of the end connectors brings its penalty in increased inductance just as surely as does decreased polar pitch. Here, as elsewhere, the designer is perpetually between Scylla and Charybdis, and whichever he chooses he is likely soon to adjudge the other preferable. Probably the most valuable means of getting a little leeway in the design of induction motors is to let up on the extreme requirement for constancy of speed, i. e., slightly to increase the losses in the secondary winding, compensating for the loss elsewhere. It makes a vast difference in the ease of design and in the cost of getting other good qualities whether the slip at load is two per cent. or four per cent., while as a practical matter of every-day use, the latter specification is, in nineteen cases out of twenty, quite as appropriate as the former. Mr. Hobart has done the art of design a service in forcibly pointing out one of the limitations which is sure to be encountered in building motors of the freak class sometimes demanded. Induction motor design, like all design of electromagnetic mechanisms, is a matter of finesse, of adroit compromise between conflicting requirements, and he is most successful at it who knows best the lengths to which he can go in any direction without defeating his ends. Practical papers like the one under discussion are, therefore, very important in bringing to hand the data on which construction must be based, and in defining the bounds of improvement.

Radium at the Technology Club.

The Technology Club of New York, composed of graduates of the Massachusetts Institute of Technology, has held some very interesting meetings this winter, the last of which was devoted to the subject of radium, and was held at the consulting rooms of Dr. W. J. Morton, professor of electrotherapeutics in the New York Post-Graduate School and Hospital. The unusual facilities of the doctor's laboratory enabled some very striking demonstrations to be made.

Dr. George F. Kunz, of Tiffany's, who has devoted so much time lately to radium and radioactive materials and the problems of the subject, gave first an interesting address on the general theme of his researches, to which attention has been called from time to time in these pages. He exhibited a number of specimens of radium and demonstrated their activity, including the first sample of American radium, and some radium ore obtained from deposits discovered in Colorado. He also made an exhibition of a sample of actinium, this being the first time it is said that it had been shown in New York. One striking experiment was where Dr. Kunz enclosed a minute sample of radium in its glass and rubber tube within three heavy outer tubes of lead, copper and iron, and then succeeded in making a diamond fluoresce brightly in the dark. This experiment was also repeated with success after placing the diamond at the bottom of a goblet of water. Dr. Kunz also made a very pretty illustration of radioactive effect by causing the diamond to fluoresce in contact with the mass of pitchblende which he had on his table. He also had a fine specimen of willemite and samples of Kunzite to demonstrate their sensitiveness and responsiveness to radium.

Dr. Morton made a most brilliant and charming address on the general subject of radium in relation to medicine, and expressed great hopefulness with regard to the treatment of cancer and diseases of that type by radium and the X-ray. He spoke of results in several cases of disease not far advanced in which certain improvement, if not entire cure, had decidedly resulted; and he exhibited to the engineers present the apparatus employed in such work, explaining as well the various methods and principles upon which such cures could be attempted and effected. He created the utmost interest by referring especially to his own original work on the utilization of the artificial fluorescence of living tissue. It will probably be remembered by our readers that as far back as last June he contributed to our pages an article on this subject, in which he stated that he had then been treating cancer for over a year on this basis with results which could not be obtained by the X-ray alone. We may refer our readers to the article in the issue of June 20.

Dr. Morton exhibited five bottles of fluorescent liquids or solutions of quinine, æsculine, fluorescin, resorcin, etc., all of which he described as beautifully fluorescent under radioactivity. Hence, if taken internally and the patient be then exposed to radioactivity, the violet rays are, so to speak, liberated or produced within the body and all the internal tissues are, in effect, bathed in sunshine. In this way there is set up in the part affected that actinic stimulus which is so beneficial to the human tissues if applied in the proper way and quantity. Dr. Morton referred to other work of this character, especially that which has been done in connection with the Curie laboratory in Paris, and did not hesitate to express great hopes as to what might come of such work in the future. His remarks were full of suggestiveness, as, for example, in regard to the immemorial use of mineral springs, whose waters he thought from the fact that they gave helium emanations might be regarded as especially radioactive, and for that reason, more than any other, beneficial in their inward and outward effects. The bottles of fluorescing liquids were exposed by Drs. Morton and Reeves to the influence of the X-ray, so that the whole audience could see the row of them vividly fluorescing under the action of the ray in the darkness, confirming the statements that had been made as to this phenomenon.

The publication of Dr. Morton's statements in all the newspapers the following morning was followed by a perfect storm of publicity, criticism and discussion all over the country, from which it may be inferred that the authenticated facts given to the engineers, and the theories advanced may be productive of a great advance in the science of electrotherapeutics, particularly as related to radium and the X-ray. The remark of Dr. Morton that these liquids had been humorously dubbed "liquid sunshine" has been caught up, and the phrase has already gone into the popular slang of the day.

The Institute Annual Dinner.

Preparations for the annual dinner of the American Institute of Electrical Engineers on February 11, at the Waldorf-Astoria, are being pushed actively, and provision is being made for 500 guests on that very interesting occasion. The notices to members, with details, will be issued in a few days. In the meantime some particulars can be given as to the arrangements. Tickets for the dinner will be $7 per cover, without wine, and $5 for ladies. A great many ladies are expected, as members are making frequent requests for such tickets. The ball room at the Waldorf is to be occupied, and Mr. Arthur Williams, chairman of the committee on decorations, is making admirable plans in regard to enhancing the beauty of that stately chamber. Mr. Calvin W. Rice, chairman of the Institute reception and entertainment committee, has already completed his plans for the exercises, which may now be briefly outlined. President Arnold will make an address and then Mr. Samuel Insull, chairman of the Edison Medal Association, will present to the Institute, on its behalf, the Edison medal, of which the Institute has already accepted the trusteeship. The gift will be accepted on the part of the Institute by Dr. A. E. Kennelly, of Harvard University, past president. The medal having been founded for the competition of electrical engineering graduates in universities and colleges in the United States and Canada, it will also be accepted in that respect by Prof. C. F. Brackett, of Princeton University, who was the first to make scientific tests in this country of the incandescent lamp. Mr. J. B. McCall, of Philadelphia, president of the Association of Edison Illuminating Companies, will then respond for that body, and Mr. C. L. Edgar, of Boston, president of the National Electric Light Association, will speak on behalf of the interests represented by that influential organization. Mr. T. C. Martin has been appointed toastmaster. Music is to be liberally interspersed throughout the proceedings, and the speeches, while brief, will derive unusual interest and importance from the occasion, which is intended to celebrate the twenty-fifth anniversary of the successful development and introduction of the incandescent lamp. There is also being prepared a handsome and artistic menu, which will embody several features of interest, and which will deserve being preserved as a souvenir of the event. Mr. Edison is to be present as a guest, but it is to be doubted whether he will break his invariable rule of never making any speeches.

Annual Meeting of Contractors.

The annual convention of the Electrical Contractors' Association of New York State was held this week at the Building Trades' Club in New York City, and was largely attended by contractors from all parts of the State, while many others from all parts of the Union were present for kindred national purposes, including Mr. E. McCleary, of Detroit, president of the National Electrical Contractors' Association. As our readers are well aware, the proceedings of these bodies are not of a public character; but it may be noted that changes among the New York State officers were made as follows: President, Marshall Barnes, Troy; vice-president, J. R. Strong, New York City; secretary, F. Fish, Rochester.

On the evening of January 19 the association gave its annual dinner, Delmonico's being the place selected, and some 120 sat down to the tables in the red room, the table reserved for the "baldheads" being illuminated with a "Hylo" lighthouse flashing a red light, over which a Tammany tiger appropriately wagged his tail and licked his chops. The only speech of the evening was an admirable address before dinner by Mr. J. C. Hatzel, although Mr. C. L. Eidlitz was perforce compelled to deliver several brief speeches in declining to deliver any. Among the guests were representatives of the inspection and insurance interests of the city: Prof. G. F. Sever, of Columbia University, and consulting engineer of the Department of Gas, Water and Electricity; Mr. G. H. Guy, secretary of the New York Electrical Society, and the technical press in the persons of W. H. Morton, Charles W. Price and T. C. Martin. After dinner, instead of speeches and toasts, there was a splendid vaudeville show with Mr. Eidlitz as impresario. The songs and dialogues abounded in clever personal "roasts" and gags, which were hailed with thunders of applause and laughter by all, even the victims.

Plant of the Columbus Power Company, Columbus, Ga.

THE city of Columbus, Ga., is an example of a thriving municipality which owes its existence very largely to the natural advantage of proximity to a large water power. Though it is located in a fertile cotton region and at the head of navigation on the Chattahoochie River, so that it has, on that account, a leading cotton shipping business, it also stands opposite a remarkable series of shoals in the river carrying a large amount of water. The Chattahoochie River drains a watershed of something like 3,500 square miles, and while it has the disadvantage common to most of the rivers of this section that it must pass great, quick-rising floods, it possesses a low-water flow that has encouraged several comparatively large power developments. Its channel for a long distance approaching Columbus is lined with precipitous rock banks confining the water in a way that causes quick changes of level, but otherwise favors impounding the water for successive utilization or periodic storage.

For a distance of 34 miles above Columbus, that is, to West Point, Ga., the power possibilities of the river may be apprehended from the fact that in this stretch there is a fall of 362 ft., 120 ft. of this occurring in the last four miles above navigable water. This last fall is distributed in a number of shoals which have long been harnessed to a greater or less extent, notably by the Eagle & Phœnix Mills. The low-water flow is probably 1,000 cu. ft. per second, so that there are available in the immediate vicinity of the city for the 120-ft. fall, some 13,500 gross hp. The average power, however, for the four miles of river in question would seem to be about 75,000 gross hp, this calculation being based on observations made at West Point for the State Geologist under the direction of Mr. B. M. Hall, hydrographer, and during 1896, which was a dry year. These figures indicate that the average flow for that year was about 4,650 cu. ft. at West Point, or, allowing 18 per cent. increase for the tributary streams between the two places, about 5,500 cu. ft. at Columbus. The flood water is sometimes ninety times greater than the low water.

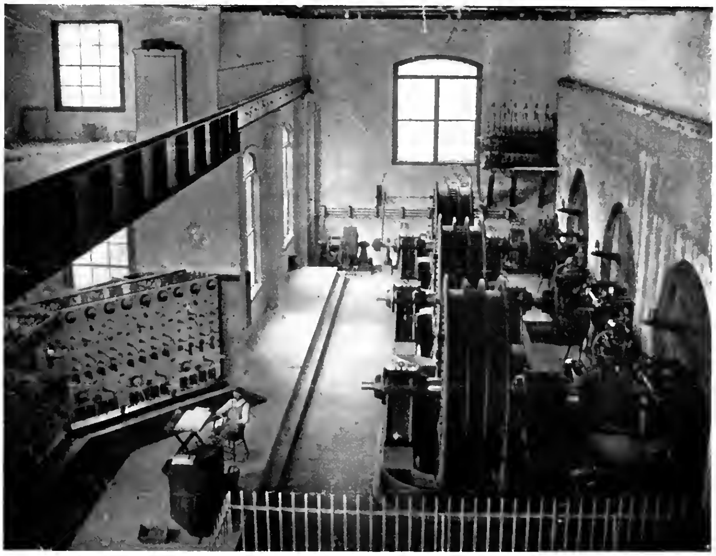

FIG. 1.—INTERIOR VIEW OF COLUMBUS POWER HOUSE.

The power plant which forms the subject of this description was built by the Columbus Power Company to furnish electric power for public sale and to drive a mill constructed on the Georgia bluff of the river. The plant, which has been in operation for about three years, is located at a shoal known as Lovers' Leap, just beyond the limits proper of Columbus, and it was planned to obtain a head of 40 ft., so that when there is a multiplicity of plants on the river above it or the number of storage dams are sufficient to regulate the discharge of the river, an average of 25,000 hp can be approached. The development is of the class in which the power house is located at one end of the dam, so that the forebay is impounded by the dam and power house structure and no penstocks are necessary. This, however, applies to the main power house or power house No. 1. The power utilization for driving the mill has been made without employing electricity, the power delivered by the wheels being transmitted to the mill by means of a rope drive. The power house for this purpose, No. 2, is located a short distance down stream from power house No. 1 and is supplied with pressure water by means of penstocks let through the bulkhead wall which extends from house No. 1 to the river bank. In both cases tail water is discharged into the excavated river bed beneath the houses and the tail water reaches the main current a short distance below, the tail race channel being separated from the main stream by a wing wall formed by the rock excavation from the tail race. Power house No. 1 is designed to develop 6,000 hp in six units and No. 2 about 3,000 hp, mainly in two units. Half of each installation is now in place.

The dam is an interesting structure of boulder concrete masonry with a cut stone spillway surface. It stands at an average of about 33.5 ft. above the stream bed, bringing its crest at elevation 138.5, and it has a length of 975 ft. 8 in., with a rollway 727 ft. 8 in. long.

Power house No. 1 is 137 ft. long and 52 ft. wide and stands at the ends of the dam at an angle of 103° with it. It rests on heavy stone masonry foundations, the up-stream portions of which form the heavy bulkhead, which is continued beyond the power house into the river bank. This bulkhead is pierced by the six openings for the six units which will form the ultimate installation of the plant, a smaller opening for the exciter units and a large opening for the penstocks leading to power house No. 2. The openings in the bulkhead for power house No. 1 are short flumes or chambers in which are set the turbines, and the back end of each of the wheel chambers is closed, as usual in plants of this type, with a heavy plate or cover of cast iron and steel, on the other side of which is the main generator room. The power house proper is thus really located immediately beyond the bulkhead containing the wheel chambers and spans the beginning of the tail race, into which the wheels discharge by draft tubes inclined through the masonry of the bulkhead from the wheel chambers. The interior view of the station thus shows a row of alternators, which are direct-connected to the wheels, and presents an unusually pleasing aspect owing to the uniformity of apparatus and the general interior finish. The walls above the windows, which are unusually large for a water power plant, are of brick and the upper parts are painted white; the lower parts and the inner side of the roof are painted drab and the steel members of the roof trusses are black. At the middle of the station there is an extension 43½ ft. wide, giving the room at the center a width of 45 ft. This was provided for the switchboard on the main floor, switching apparatus below and lightning arresters and other devices above, where the transmission lines leave the building. The roof is of the ridge form with a hip over the switchboard addition, and monitors are provided for both the main and hip roofs.

The racks are of the usual construction supported on a framework of I-beams, giving the racks an inclination of about 12° with the vertical. The wheel chambers have a depth equal to the width of the upper part of the bulkhead, 21 ft., and are built with concrete floors, stone walls and brick arches 2 ft. thick, the arched roof on a 6-ft. radius. The gates to the entrance of the wheel chambers are of planking and are lifted by hand by means of a rack and pinion. The gates have cast-iron guides, bolted through the masonry to the cast-iron head at the down-stream end of the wheel chambers.

Each of the main wheel chambers contains a pair of horizontal 39-in. Hercules turbines made by the Holyoke Machine Company. They discharge into the same draft tube. The center of the wheels is 15 ft. below normal head water level and 25 ft. above normal tail water level. Under the total head of 40 ft. each pair of wheels develops 1,484 hp at 200 r.p.m. Each draft tube is 7½ ft. in diameter at the turbine casing and expands to 10 ft. at the discharge end. It is embedded in concrete in the bulkhead wall, but the exposed surfaces of the masonry are faced with brick work. The discharge chamber in each case is 16 ft. wide and has a brick arched roof carried by piers 4 ft. thick. The piers and the arches support the floor and machinery in the generating room. On the assumption of 80 per cent. efficiency in the turbines, it will be seen that 410 cu. ft. of water are passed per second, which gives a velocity of flow into each wheel chamber of 3¼ ft. per second and through each draft tube from 9¼ to 5.2 ft. per second. The bottom of the discharge chamber was excavated to give a depth of water under normal conditions in the tail race of 10 to 15 ft.

Each pair of wheels is direct-connected to a two-phase alternator built by the Stanley Electric Manufacturing Company. At present three of these are installed. Each machine has a rated capacity of 1,080 kw at 6,000 volts and driven at 200 r.p.m. gives current at 60 cycles. Each is joined to the shaft wheels by a flexible leather coupling of the star shape. Under present demands two of the machines suffice, leaving the third as a reserve. Ordinarily, one of the units is run under constant gate at the turbine, while the other is controlled by a governor made by the Schenck Governor Company, of Meriden, Conn., which takes up the variations of the load by means of gate movements on the second pair of turbines. To the governed alternator a Queen recording tachometer is attached, this as a safeguard in the matter of speed, as most of the motors driven by the station are of the synchronous type. Both of the generators are started a little before 6 A.M. and one is shut down at 5.30 P.M., and the other at 11 P.M. During the noon hour one-half to two-thirds of the load is dropped and a similar drop takes place at 5.30 P.M., when the mills close, in case a few of the mills are run over-time; otherwise the load drops to one-sixth, being largely a demand for lighting.

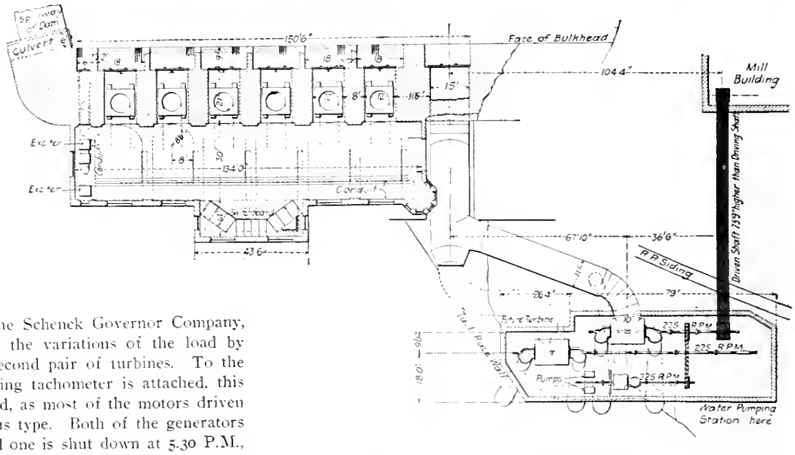

FIG. 3.—PLANS OF STATION OF COLUMBUS POWER COMPANY AND OF THE BIBB MANUFACTURING COMPANY PLANT.

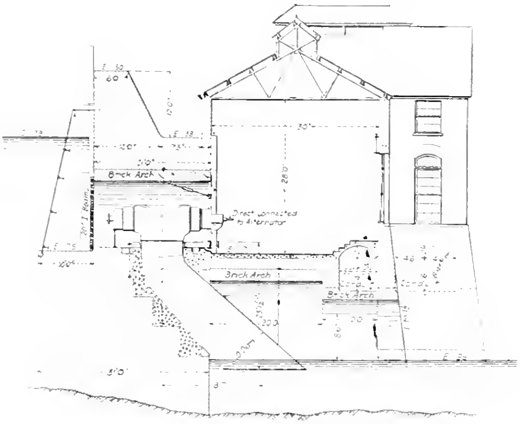

FIG. 2.—CROSS-SECTION OF COLUMBUS POWER STATION.

There are two exciters directly connected to a single 18-in. Hercules wheel located in a chamber 4 ft. wide at the end of the station nearest the dam. Each exciter, which is of the Eddy type, has a capacity of 60 kw at 75 volts running at 450 r.p.m. They are at present operated at 60 volts and each generator takes at the present normal running from 70 to 80 amp. for the field current. During May the output of this plant was about 1,350 kw, so that power required for the field is less than 1 per cent. of the total. The modest requirement of energy for the field is in part due to the fact that the load is nearly all of synchronous motors, except for some lighting. The comparatively few induction motors in use are small and do not cause a noticeably lagging load. The exciters are operated under the control of mechanical governors.

The main generators have an efficiency of 96.4 and 96.5 per cent., and it is stated that the temperature rise in the armature coils has never been more than 15° above that of the room. This statement applies to a case where the load was seven-eighths of the rated and the room temperature 99°. The generator room is served by a 10-ton hand power traveling crane built by Chisholm & Moore, of Cleveland, and running the entire length of the room.

One of the interesting points in connection with the hydraulic equipment is the provision made for operating one of the flood gates in the dam by means of oil under pressure. Above the flood gates there is attached to the dam an hydraulic lift which consists of a large heavy cylinder and piston for lifting and lowering the flood gate by hydraulic pressure. Oil is used instead of water, so that difficulties due to freezing are obviated. The system is designed for 750 pounds' pressure and the piping is extra heavy with malleable footings. Pressure is maintained by a Stilwell-Bierce 1 x 6-in. triplex pump belt driven from one of the exciter units.

One of the features of the plant is the arrangement of the switchboard. When entirely completed this will consist of ten marble slabs erected to form three sides of a polygon, so that the switchboard attendant standing toward the center of the polygon can readily see all panels from the one position. Two sides of the polygon are at present installed and when the remaining three alternators are in place the third section will be erected. Another of the features of the plant is the provision of large cement-lined conduits under the floor of the station for the passage of conductors. These are virtually tunnels running lengthwise of the building, one under the generator room and the other under the switchboard ell, both painted white, lighted by incandescent lamps and nearly large enough for a man to walk through. As shown in the accompanying illustration, the wires and cables are neatly arranged on supports, which are creosoted wood easily distinguished against the white interior.

The section of the switchboard at the right consists of three generator panels. Each of these is divided into three parts, the uppermost carrying the indicating instruments, the middle the circuit-breakers, and the bottom instruments employed for the field current. The indicating instruments comprise two ammeters, one for each phase, and one voltmeter with the usual plug switch. There is also a pilot lamp and a synchronizing lamp. The circuit-breakers are of the oil-brake type used as switches and each is of the double-throw pattern, as there are two sets of bus-bars. On the bottom panels is a field ammeter and a rheostat wheel. An interesting point in this connection is the use of a small pulpit facing the switchboard, containing three rheostat wheels. Each of these is connected by shaft and gear under the floor with the gearing actuated by the rheostat wheel on the generator panel, so that the field current can be regulated either from the pulpit or from the switchboard. The connection of these two wheels is indicated when the operator moves the wheel on the pulpit, as the wheel on the switchboard turns simultaneously with it.

The center section of the switchboard contains a panel for the exciters and space for three feeder panels, of which two are now in position. The exciter panel at the upper part contains a voltmeter and two ammeters, these for the two dynamos; at the middle two three-pole, single-throw switches, one for each machine, including the equalizer connection; and at the lowest the field rheostat controller. Each of the feeder panels is similar to the generator panel except that it also has two ground detectors and two recording wattmeters.

As already stated, the power from the plant is delivered largely to synchronous motors. Two of the largest motors driven by the plant are located about 1,500 ft. distant in a comparatively new mill erected by the Columbus Manufacturing Company. One of these is of 600-hp capacity at 225 r.p.m., and the other of 400 hp at the same speed. Each is started by an independent induction motor spur-geared to it, these operated from the plant through transformers, which step down the pressure to 575 volts. The pressure at which the synchronous motors are designed to run after the synchronous speed is reached is 5,500 volts. Exciting current is obtained from a 9-kw, 125-volt dynamo, belt-driven from the main shaft. The synchronous motors are placed in line with each other, the switchboard faces them, the transformers are located in a separate room and the power plant generally for this mill presents a very fine appearance. The motors drive large sheaves carrying an European rope drive for the mill proper. The electric apparatus in this plant is of the General Electric manufacture and the switchboard is equipped with standard apparatus.

FIG. 4.—POWER DAM ON THE CHATTAHOOCHIE RIVER.

Power house No. 2 was erected to furnish power direct to the plant of the Bibb Manufacturing Company, whose mill is located on the bluff above Lovers' Leap, and to furnish light and water to this mill and the mill village. It contains space for two pairs of large water wheels and one smaller one, all of which are supplied with water from the forebay by a 15-ft. steel feeder pipe brought through the bulkhead alongside the inner end of power house No. 1. This feeder passes underneath the entrance to power house No. 1 and is divided into two branches, one 10 ft. in diameter and the other 11 ft. Each branch is planned to conduct the water to one of the large pair of wheels, and the larger penstock, in addition, serves the single wheel through a branch pipe 5 ft. in diameter. Power house No. 2 is located about 40 ft. below power house No. 1 and about 100 ft. below the forebay; the penstocks are, accordingly, short, and they are supported on brick piers 6 or 7 ft. apart and 3 ft. thick, with a rock fill between piers. The comparatively complex run of pressure piping and draft tubes resulting is indicated in the accompanying drawings. Each pair of the larger wheels, which are 36-in. horizontal Hercules wheels, is designed to drive a horizontal shaft at 225 r.p.m.; one of the units has been installed and is capable of developing 1,500 hp, which is transmitted to the Bibb mill by means of a rope driven on the American system installed by the Dodge Manufacturing Company. The single wheel is a 24-in. horizontal turbine and is used to drive the water-pumping machinery and the lighting generator.

The rope drive for this mill is an interesting one. The receiving shaft for the power transmission is 60 ft. higher than the driving shaft and approximately 116 ft. from center to center of the sheaves. Altogether there are about 7,000 ft. of rope carried in the drive, consisting of 30 wraps of 1½-in. manila rope. The driving sheave in the power house has a wooden enclosure fitted with window glass, while the transmission line between plant and mill is protected with a sheet-iron covering. This is stiffened by lateral angle irons, which also serve to discharge rain sidewise, so that it does not fall in a continuous stream toward the power house. The turbines are controlled by a Schenck governor to maintain a constant speed. The second unit to be installed is to have a capacity of 1,000 hp and the driving sheaves in the rope tower are mounted on quills with this idea in view, so that various drives can be shut down while allowing others to run, the drive in the mill building being of the usual class in which floors or departments are made independent. The quills are carried on an 8½-in. forged shaft which runs at 300 r.p.m. These various sections of rope transmission are provided with the usual electric tell-tales, so that any defects can be located and electric push buttons are conveniently located on each floor of the mill to signal the power house for stoppage of machinery at any time.

The single wheel in power house No. 2 has a capacity of 225 hp and drives a shaft from which the rest of the machinery is driven by belt. This includes a Stanley lighting unit of 150-kw capacity, giving three-phase alternating current at 250 volts and 75 cycles, running at 1,000 r.p.m., a Holyoke rotary duplex fire pump and a centrifugal pump and a triplex pump for the general water system. The Stanley machine is excited from a Northern Electric dynamo of 2-kw capacity and 120 volts belted to the generator.

FIG. 5.—POWER HOUSE, COLUMBUS, GA., BIBB MANUFACTURING COMPANY PLANT AT RIGHT.

The lighting system for Bibb City and mill is controlled from a switchboard in power house No. 2. There are eight feeders all told, five for mill lighting, one for arc lighting, one for the village houses and one for the office and boiler house. Each of the feeders is controlled by a three-pole, single-throw switch. The switchboard contains panels for the generator and standard instruments throughout. There were 101 houses in Bibb City in May for the mill operatives, each of which is supplied with water and with electric light free of charge. It will be interesting to add that the rent of the houses is based on the number of rooms and is 25 cents per room per week. Power house No. 2 has white brick walls with a slate-color wainscotting around the bottom and the under side of the roof is drab with a black striping on the roof members, which are of timber.

The water works comprise a large centrifugal pump for drawing water from the wheel case of the Bibb mill unit, a Deane triplex pump for lifting the water to the tank on the bluff and a New York filter of 500,000 gallons daily capacity. The centrifugal pump is only used when the pressure of water in the wheel case is insufficient to pass the water through the filter, which carries 7 ft. of sand. Besides the filter there is the usual settling tank and clear water basin, and from this the Deane pump, which has 6 x 8-in. plungers, discharges to the storage tanks. One of these is of 100,000-gallons capacity for the general water supply of both the mill and the village, another is of 35,000-gallons capacity for fire purposes and a third is of 5,000-gallons capacity, situated in a tower of the mill and used for flushing purposes. The fire tank is, of course, connected independently to the fire pump. The large general storage tank is about 233 ft. above the pump and the smaller tank about 50 ft. lower than the large one. The discharge pipe from the pump has two branches, one to each tank. The flushing tank is provided with a large float gauge which is visible from the pump house and six or eight times a day the tank has to be filled. For general purposes between 60,000 and 70,000 gallons are pumped twice a day and the pump is operated on the branch that leads to this tank about two hours at a time. The centrifugal pump and both the filter and settling tanks can be by-passed at any time. The fire pump has two shafts which carry grooved wheels for friction driving.

The plant was designed by Mr. William C. Whitner, chief engineer of the water power development for the Virginia Passenger & Power Company, of Richmond, as chief engineer, and was constructed under the direction of Mr. William S. Lee, Jr., now chief engineer of the Catawba Power Company, near Rock Hill, S. C., as resident engineer. The officers of the company when the plant was erected were as follows: H. M. Comer, president; J. F. Hansom, G. Gunby Jordan, E. T. Comer and John Hill, directors. Mr. H. A. Tibbs is engineer of the electrical department.

The dam and power house were erected by Hardaway, Jones Company, of Columbus, contractors. The cost of the development completed will be about $450,000, or $50 per horse-power.

Radioactivity and Radiation.

By Dr. Louis Bell.

WITHIN the past year or two experiments on radium and other sources of radioactivity have been so multiplied and so diverse in methods and objects that it has been well nigh impossible to keep track of the work, much less to arrive at a clear appreciation of its significance. We have all got to speaking so glibly of electrons and ionization and such like things that we almost forget the distinction between hypothesis and fact, and take seriously a great deal of hasty deduction from imperfect data. Unhappily, the non-technical press has promulgated columns of misinformation under "scare" head lines. It is my purpose here not to discuss theories of radioactivity or to summarize the great mass of experiments upon the subject, but rather to call attention to some of the collateral researches which have thus far been lost in the shuffle or hastily assumed to confirm preconceived notions.

The point of view assumed in most recent work on radioactive substances has required that their properties should be explained in terms of electrically-charged atomic fragments. This line of work has certainly been fruitful, but in pursuing it very many experimenters have lost sight of everything else and particularly have forgotten the very existence of ordinary radiations of which visible light is the type. I long ago predicted that there would be a recrudescence of the emission theory of light as a result of this tendency to jump at conclusions, and such in fact there has been, but the wave theory is too firmly grounded to be shaken on any casual disturbances, and no one as yet has had the temerity to risk a serious assault.

Meanwhile some very important work has been done upon forms of ordinary radiation hitherto unknown or neglected, and the results are such as to demand attention. The work of Blondlot on the N-rays in particular is very far-reaching in its results, and throws much light on our hitherto very imperfect knowledge of the possibilities of wave radiation. Oddly enough, his work has attracted extraordinarily little attention outside of purely scientific circles.

The substance of it is that a large group of rays has been detected which has, as a whole, properties closely akin to those manifested by radioactive substances, but which is subject to the ordinary laws of radiant energy. The N-rays have a profound effect upon the conditions of electrical discharge, and were, in fact, detected by their accentuation of the electric spark; and yet they are reflected, refracted and polarized precisely like ordinary light. They produce a vigorous secondary activity in virtue of which bodies upon which they fall continue for a time to give out N-rays by a species of phosphorescence. One of the curious effects of this property is that the N-rays may seem to penetrate bodies in reality highly opaque to them, although their penetrative powers are actually rather conspicuous, yet selective in a way totally different from that found, for instance, for radium radiation. The N-rays seem to be received as part of the solar radiation, and hence are very widely found aside from their occurrence in the radiation from ordinary flames. Blondlot has not definitely determined their wave length, which probably varies over a considerable range, but it appears to be very great, forming a sort of connecting link between the low heat rays and the Hertzian waves of appreciable dimensions. They are very strongly refracted by quartz, which seems to present the phenomenon of anomalous dispersion for waves of this length.

Truth to tell, the spectrum from no source of radiation has as yet been completely investigated. It may be well known within a limited range, but that is all. Opacity is purely a relative term, and a given substance may stop completely ordinary forms of radiation and yet transmit energy of particular kinds with the utmost freedom. In view of such facts as these it is wise to go very slowly in the study of unusual manifestations of energy. Moreover, the theory of anomalous dispersion indicates that a substance may transmit certain wave lengths substantially unrefracted and inferentially unreflected, so that while the presence of reflection and refraction indicates that a given radiation is of the general nature of light, the absence of reflection and refraction does not necessarily remove it from this category.

A case somewhat analogous to the N-rays is found in a type of radiation recently studied by Sanford and reported in the *Physical Review*. The radiation in question proceeds from the cathode of an air condenser under high electric stress. It possesses strong photographic activity, and sets up strong secondary radiation of a similar but not identical kind. It has strong penetrative powers as regards some opaque bodies. When first announced it was regarded by some notable authorities as a clear case of cathode rays consisting of electrons, but on more complete investigation it turns out that it can be refracted, reflected and polarized, and is very probably ordinary radiation of short wave lengths, although the actual wave lengths have not yet been determined; and it is possible that anomalous dispersion may be concerned here, as with the N-rays whose index of refraction would have assigned them to the extreme violet at first sight.

The concurrent existence of material stream rays and ordinary rays like this and in the emanations of radium and the like make the resulting phenomena very difficult to diagnose. There is especial danger of confusing cause with effect and secondary effects with primary ones. For a complete solution of the problems presented, a far better knowledge of generalized ordinary radiation is necessary than is yet available, and in the case of radium et al. the chemistry of the substances needs persistent study to a degree which is very difficult considering the rarity of the materials. How much would we know of the wonderful and intricate phenomena resulting in the production of the photographic image if metallic silver had never been isolated and a rather impure silver bromide brought a hundred dollars a gram? It is a terrible handicap in the investigation to be cut off from ordinary chemical methods, and without their aid it would be little short of miraculous if serious blunders were avoided. As regards radium, the latest point is its breaking up, with the production of helium and another gas as yet unknown. As to the result there is no doubt, but it is quite another matter to explain where the helium comes from and whether it resulted from the decomposition of a chemical compound or the disintegration of an element into its primal constituents. A hundred grams of radium in skillful hands would answer many questions, but it is not forthcoming at present, and it is worthy of note that the Curies, who know the most about the chemistry of the wonderful stuff, scrupulously avoid sensational hypotheses and hold open minds for further developments. Their example is a good one for those less well informed to follow.

This is not written in the least as a counterblast against the very important and beautiful work that has been done in the study of radioactivity, but merely to call attention to the very imperfect knowledge of some of the possibly essential factors in the phenomena.

It is always unsafe in science to build too fast, lest the foundations prove faulty, and in the rapid progress made in the study of radio-activity a good many gaps have been left perilously near the bottom of things. In due time these may be filled up—or not, as the event may prove. But the material gathered is priceless and science can well afford for the sake of it to forgive any errors that may prove to have been committed in haste and enthusiasm. It is the final result that is important, not the peccadillos of the workmen.

A Method of Photographing Alternating-Current Wave Form.

By C. J. SPENCER.

MOST central power stations are equipped with alternating-current machinery. Records are kept of ammeter, voltmeter and wattmeter readings, but very few have any records of curve shape. The shape of the curve often differs from the pure sine wave form. A peaked wave may have a maximum value considerably greater than that calculated from instrument readings, which are usually the square root of the mean square value. Thus two sources of e.m.f., giving the same value by voltmeter, may have such different maximum values as to require different insulations. Transformer losses are less for a peaked wave than for a flat-topped wave. It is, therefore, important that the wave shape be measured.

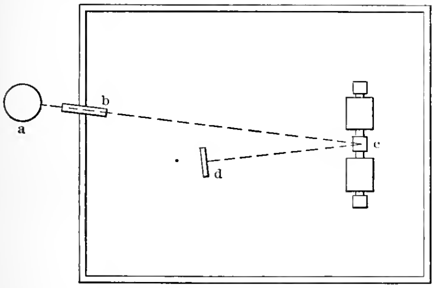

FIG. 1.—GENERAL ARRANGEMENT OF APPARATUS.

The following method of photographing alternating-current wave form was devised by the writer while at Johns Hopkins University during the winter of 1897-98:

Fig. 1 shows the general arrangement of apparatus. An arc lamp is placed at *a*, a telescope at *b*, galvanometer at *c*, and photographic apparatus at *d*. The heavy lines show the boundaries of a dark room and the dotted lines show the path of light.

The arc lamp has no points of interest except that it must be alternating if a measure of time is desired. The telescope is intended to focus the light of the arc lamp on the galvanometer mirror. The galvanometer consists of an electromagnet and a moving coil with mirror, as shown in Fig. 2. It is essential that the moving parts be light and sensitive and that the suspension be stiff.

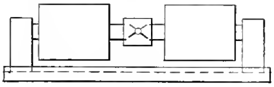

FIG. 2.—DIAGRAM OF GALVANOMETER.

A kodak film on a roll, *a* (Fig. 3), with the end of the black paper attached to the film, fastened to roll *b*, which is turned by the spring, *c*, constitute the photographic apparatus. The path of light is at *X Y*.

The method of procedure is to connect the e.m.f. terminals to the galvanometer coil through a suitable non-inductive resistance. The arc lamp, galvanometer mirror and photographic apparatus are then adjusted until the light is seen to move along the path *X Y*. Roll *a* is then released and the film allowed to roll on *b*.

One-half of a period of an alternating current wave taken by this method, with the zero line drawn afterwards, is shown in Fig. 4. The light and dark spots are caused by the alternations of current in the arc lamp, and are an excellent measure of time. A 133-cycle current supplied the arc lamp, so the space between centers of dark spots represents 1/266 of a second. It might be supposed, on inspecting this curve, that the shape is due to the galvanometer period being too long. This is not the case, however, for the same curve taken by different methods had the same appearance for reasons given below.

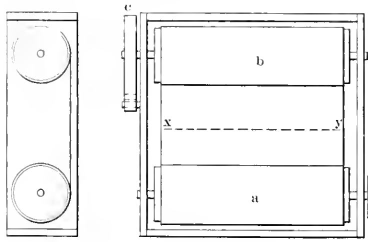

FIG. 3.—KODAK FILM.

The curve is that of the e.m.f. induced in the secondary of an induction motor. This was first investigated by Dr. Louis Duncan, who published the results of the test in the *Transactions* of the American Institute of Electrical Engineers in 1892, though he used a point and contact method for obtaining his results. The motor had collector rings attached to the secondary, for inserting resistance at starting, and was geared to an inverted rotary converter, supplying alternating current to the induction motor primary, with a gear reduction to give a known percentage slip. The converter thus drove the motor as a dynamo, with the secondary circuit practically open, one pair of slip rings being connected to the galvanometer through a high resistance. The reason for the curve being so irregular was on account of the construction of the motor, which had inwardly projecting pole pieces. The strength of the magnetic field decreased as it moved from a pole piece to the space between poles, and again increased at the next pole, thus giving a pulsating e.m.f. superimposed on the alternating e.m.f.

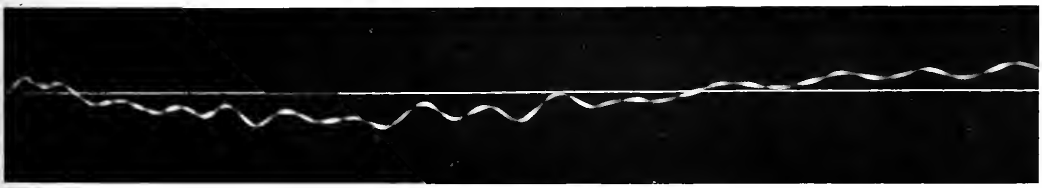

FIG. 4.—ALTERNATING-CURRENT WAVE.

My apparatus for taking curves consisted in what I could find in our laboratory. The telescope was an iron gas pipe with a concave and a convex lens, of different focal lengths, stuck on opposite ends with sealing wax. A large electromagnet weighing about 100 pounds and intended for making experiments in magnetism, where great magnetic densities were required, served for the main part of the galvanometer. I made the coil with No. 36 B. & S. insulated wire, by winding the wire on a rod in a lathe, then pulling the coil thus formed out straight and wrapping a piece of No. 26 spring brass wire around each end. These pieces of wire when pulled taught made a very stiff suspension. Fig. 5 shows the coil in place. The suspension wires were fastened to fibre pieces, which were adjustable on a continuously-threaded brass rod, all being fastened in a brass box painted black. The mirror was very light and thin, about one-eighth inch in diameter, and fastened to the coil with wax. I did not photograph the reflection from the galvanometer at its own period, for it would have only shown a band of light. The period was very short.

I would suggest several improvements on the above apparatus. It should plot the zero line at the same time as the curve. This could be done by focusing a second spot of light to coincide with that reflected from the galvanometer mirror, when the coil is at rest. The line traced by this stationary source of light would serve as the zero line. It would be preferable to have the zero line traced by light from an alternating-current arc lamp, supplied by current of known frequency, and the curve plotted by reflected sunlight, or other light of great intensity. A second desirable addition would be to calibrate the curve with a direct current of known voltage. This could be done by impressing the known direct e.m.f. on the

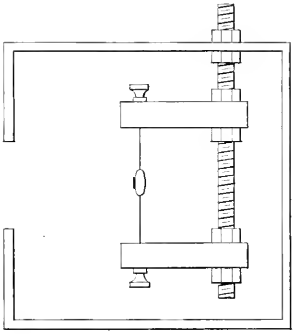

FIG. 5.—DIAGRAM SHOWING COIL IN PLACE.

galvanometer coil, while the film is moved a short distance, then reversing the e.m.f. on the galvanometer coil, while the film is again moved. Several values of e.m.f. can thus be photographed before taking the curve.

The above galvanometer is only suitable for tracing e.m.f. curves. In case it should be desired to trace a current curve, the field could be produced by a coil carrying the alternating current, provided the inductance due to producing the magnetic field is small compared to the rest of the circuit, and the moving coil is actuated by a direct current of constant value. A combination of alternating-current field and alternating e.m.f. impressed on the coil would give the power curve.

The Choice of Air Gap Diameter for Induction Motors.

By H. M. Hobart.

A COMMON error in induction-motor design consists in employing too great a rotor diameter with the intention of obtaining a high-power factor. The desired result is not necessarily thereby achieved, as the inductance of the end connections—a by no means inconsiderable percentage of the total inductance—increases with increased pitch.

It is the purpose of the present article, first by the method of treatment, to show the very great percentage which the inductance of the end connections may form of the total inductance;[1] and, secondly, to propose a practical and simple method by which the best proportions may be determined.

In Behrend's excellent treatise[2] on the induction motor, the following formula for the leakage factor is given:

$$\sigma = C \cdot \frac{\triangle}{\tau}$$

in which C is stated to be a constant depending upon the shape and size of the slot, and upon other conditions, $\triangle$ the radial depth of the air-gap, and τ the polar pitch. It is stated that C varies between 10 and 15 for half-open slots. Owing to its brevity this formula is exceedingly useful if judgment is used in the choice of the constant C.

In attempting to apply to the estimation of the inductance of the windings of an induction motor, principles analogous to those he has found very useful in estimating the inductance of the short circuited turns in commutating machines, the writer compiled Table

TABLE I.—LINES PER AMP.-TURN PER CENTIMETER OF "EMBEDDED" LENGTH.

Polar pitch in centimeters.	Wide-open slots.	Half-open slots.	Completely closed slots.
20	0.86	1.04	1.24
25	0.69	0.83	1.00
30	0.57	0.69	0.83
35	0.49	0.59	0.71
40	0.43	0.52	0.62
45	0.38	0.46	0.55

I, in which the lines per ampere-turn per centimeter of "embedded" length are taken as inversely proportional to the pitch, and has found it to give results in fair agreement with practice. Lines per ampere-turn per centimeter of "free" length may be taken at 0.4 for all values of the pitch. Of course, the mechanical arrangement (*i. e.*, grouping, etc.) of the end connections occasions considerable variations in this constant. Motors with squirrel-cage rotors take 0.3 lines per ampere-turn per centimeter of "free" length, taking as "free" length that of the stator winding.

The predetermination of the inductance of the windings of an induction motor, is analogous—so far as relates to the component quantities to be considered—to the predetermination of the magnetizing current which would be required for one phase of the stator winding, were the reluctance of the magnetic circuit that offered by all the paths exclusive of that path leading through the secondary winding.

This much more restricted available magnetic path largely accounts for the low values for the lines per ampere-turn per centimeter of "embedded" length, as set forth in Table I, as compared with the average values applicable to the short-circuited turns in commutating machines, namely, 4.0 c.g.s. lines per ampere-turn per centimeter of "embedded" length, and 0.8 c.g.s. lines per ampere-turn per centimeter of "free" length.

Furthermore, in induction motors we are concerned with the inductance, not of small compact groups of conductors occupying two or three centimeters of the periphery, but of the more or less spread-out groups corresponding to the conductors per pole per phase. In most induction motors, the polar pitch, τ, i. e., that portion of the periphery devoted to one pole (the gap periphery divided by the number of poles), amounts, according to the periodicity, the normal speed, the output and the designer's choice, to from 10 cms to 45 cm.; hence the belt of conductors belonging to one phase, occupies a peripheral width of from 6 cms to 15 cms.

The radial depth of winding is not generally different from that customary in continuous-current machines. The greater width contributes in a considerable degree to the small values to be employed for the lines per ampere-turn per centimetre of "embedded" length and "free" length, in deriving the inductance.

An example of the estimation of σ is—for illustrative purposes—worked out from the constants in Table I as a basis:

Diameter of air gap	102 centimeters
Periphery of air gap	322 centimeters
Number of poles	8
Polar pitch	40.2 centimeters
Effective length of core parallel to shaft	25.4 centimeters
Mean length of one stator turn	181 centimeters
"Embedded" length per turn	51 centimeters
"Free" length per turn	130 centimeters
Lines per ampere-turn for "embedded" length	51x.44=22
Lines per ampere-turn for "free" length	130x.40=52[3]
Total lines per ampere-turn	74
Number of stator slots	120
Number per pole per phase	5
Conductors per slot	4
Turns per pole per phase	10
Lines per coil per ampere = 74 x 20	1480
Inductance per coil = 20 x 1.480 x 10^{-8}	.000296 henry
Inductance per phase = .000296 x 4	.00118 henry
Periodicity	40 cycles per sec.
Reactance per phase = 6.28 x 40 x .00118	0.296 ohm.

The slots are about three-quarters open, and we shall employ the values: 0.44 line per ampere-turn per centimeter of "embedded" length, and 0.40 line per ampere-turn per centimeter of "free" length.

But the winding—so far as relates to the estimation of its inductance—is equivalent *not* to 8 coils of 10 turns each (*i.e.*, to one 10-turn coil per pole), but to 4 coils of 20 turns each, that is, to one 20-turn coil *per pair of poles*.

The motor is for 550 terminal volts, and the stator (primary) windings are Y-connected, there being, therefore,

$$\frac{550}{\sqrt{3}} = 318 \text{ volts per phase.}$$

$$2 \times \text{reactance per phase} = 0.592 \text{ ohm.}$$

Amperes at standstill and normal primary voltage for resistance less windings $= \dfrac{318}{.592} = 536$ amperes $= A$.

CALCULATION OF THE MAGNETIZING CURRENT.

Primary voltage per phase (E)	318
Turns in series per phase (T)	80
Periodicity in cycles per second (N)	40
Flux per pole (E = 4.2 x T x N x M x 10^{-8}) (M)	2.37 megalines
Net length laminations between flanges (λ)	25.4 centimeters
Diameter at air gap	102 centimeters
Polar pitch (τ)	40.2 centimeters
Stator slot pitch	2.68 centimeters
Rotor slot pitch	2.23 centimeters
Stator slot opening	0.9 centimeters
Rotor slot opening	0.8 centimeters
Exposed iron at stator surface	66 per cent.
Exposed iron at rotor surface	64 per cent.
Mean percentage exposed iron (p)	65 per cent.
Mean cross section exposed iron per pole at air gap ($\lambda x \tau x p$)	660 sq. cms.
Correction factor for spreading of lines in gap	1.20
Corrected mean cross section of air gap	790 sq. cms.
Average air gap density	3000
Maximum air gap density (1.7 x average density)	5100
Actual radial depth of air gap	.32 centimeters
"Equivalent"* depth, air gap	.35 centimeters
Required total magnetomotive force	1430 amp.-turns
Required for one phase	715
Turns per pole per phase	10
Maximum current per phase	71.5 amperes
R.M.S magnetizing current per phase	50 amperes = B

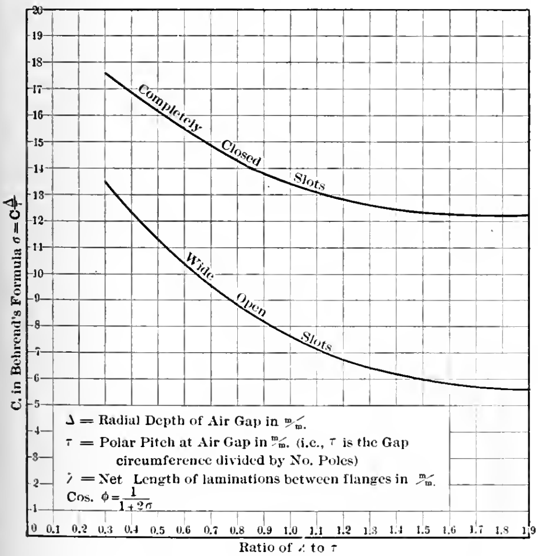

FIG. I.

"Diameter of Circle" (in amperes) $= A - B = 486$ amperes.

$$\sigma = \frac{B}{A-B} = \frac{50}{486} = .103 \; cos\,\phi \; 0.83.$$

Now, it is evident that in Behrend's formula,[4]

$$\sigma = C\frac{\Delta}{\tau}$$

it is assumed that the inductance is directly proportional to the "embedded" length alone. We know from the above method, which takes clearly into recognition the effect of the "free" length, that it is only the inductance of the so-called "active" portion of the winding that is thus directly proportional to the "embedded" length. The inductance of the "free" length is directly proportional to τ. Hence, the total inductance decreases with increasing values of τ much less rapidly than is shown by Behrend's formula, and may ultimately even increase with increasing values of τ.

Nevertheless, Behrend's formula, in virtue of its great simplicity, permits of a much more rapid and satisfactory pre-determination of σ than is practicable by the method of working from the inductance as expressed in lines per ampere-turn per centimeter of "free" length and "embedded" length, owing to thus avoiding the necessity for an independent pre-determination of the magnetizing current. It is only necessary to employ suitable constants for C, and those given in Table II have been so chosen as to give results in fair agreement with those obtained by working from the values in Table I.

TABLE II.—VALUE FOR C IN BEHREND'S FORMULA FOR

$$\sigma = C\frac{\Delta}{\tau}$$

Net length λ of core between flanges in % of Pitch (τ).	Wide open slots.	Completely closed slots.
150	6.0	12.5
140	6.2	12.6
130	6.4	12.7
120	6.7	12.9
110	7.1	13.1
100	7.5	13.4
90	8.2	13.8
80	8.8	14.3
70	9.5	14.8
60	10.3	15.4
50	11.3	16.1
40	12.2	16.8
30	13.5	17.7

These results are plotted in the curves of Fig. 1, and constitute a useful basis for the calculation of σ.

A Record for Jablochkoff Candles.

A Calcutta correspondent of the London *Electrician* says that an installation of Jablochkoff candles at Calcutta has just been superseded by enclosed arc lamps after more than 22 years of service. The installation was put down some time in 1880 or 1881 to light the grounds of the Eden Gardens and gave admirable service up to November 14 of last year, when a modern plant was put in. The original installation consisted of some 30 lamps, the wiring being carried in iron pipes to the engine house close by. After about a year the cables developed faults and had to be abandoned, and new cables were laid in teakwood troughs run in solid with pitch. To this day they are still good. There is no telling how long the old arrangements might have been adhered to had not one of the boilers been finally condemned by the inspector. There are a few more lamps of the same era still working in Bengal.

---

[1] Of course this has in a general way been recognized by numerous designers—see, for instance, a review of Behrend's treatise, contributed to *Elektrotechnische Zeitschrift*, 1903, Heft 24, by M. Breslauer—but it is doubtful whether it has been recognized that the percentage is so high.

[2] "The Induction Motor," New York, ELECTRICAL WORLD AND ENGINEER, 1901.

[3] This example is an extreme instance of the preponderating effect of the inductance of the end connections. A decidedly better motor, especially as regards higher power factor, would have resulted from the employment of a smaller diameter and a greater length of laminations between flanges.

* That is, making allowance for reluctance of teeth and core in the manner suggested by Kapp in Elektromechanische Konstruktionen."

[4] It would appear that the simplest formula which could really be said to approximately represent the facts, would be of the form

$$\sigma = k\,\frac{\Delta(\Delta + k^1)}{\tau^2}$$

k and k^1 being constants proportional respectively to $\frac{\lambda}{\tau}$ (where λ is the length of lamination between flanges), and to the depth of the slots. But it is decidedly preferable to use as simple a formula as practicable, and it is thought that Behrend's original formula $\sigma = C\frac{\Delta}{\tau}$ with the correction for the free length set forth in Table II and Fig. 1, constitutes a fairly satisfactory basis.

The New Automatic Telephone Exchange at Grand Rapids, Mich.

BY EDWARD J. HART.

The new automatic exchange of the Citizens' Telephone Company, of Grand Rapids, Mich., was "cut over" at 12:30 noon, Saturday, January 9. The complete exchange of more than 5,000 telephones was thrown into operation at that time, and only seven minutes of time were required to cut off the old manual exchange and switch in the new one. The occasion marked an epoch in the progress of the telephone industry. In point of number of telephones in operation, the exchange is the largest automatic system in the world, and the officials of the company that installed the automatic exchange state that it is the first time a large automatic plant was ever cut over in one operation; the usual practice being to cut in banks of 1,000 telephone switches according as they are ready for operation. The same officials stated that it may be a lifetime before a similar cut over is made, of 5,000 automatic telephones at one time, since conditions are usually so different, and it is usually so much more desirable to switch in fractional portions of the exchange at a time. Of the 145 telephone operators in the employ of the Citizens Company, 48 were retained to fill positions in the toll line operating room and at the information desks, and the others left their switchboards as they "died" and went out into the world to seek other employment—a regretful incident of the change to the telephone company.

The Citizens Telephone Company of Grand Rapids is essentially a home institution, owned by more than 1,200 Grand Rapids stockholders. Aside from the local exchange, it operates a large number of others in towns and villages of the state, and reaches 250 exchanges and toll points within 50 miles of the city and a large number in all parts of western and northern Michigan. It connects also with a large number of telephones in farmers' homes, including two exchanges of 60 each of "farmers'" telephones. The company was organized in May, 1895, and incorporated the following September. Its service was established in June, 1896, with 832 telephones. Its capitalization then was $100,000, but it boasts now of an authorized capitalization of $2,000,000, of which $1,400,000 is paid in, and stock is still selling. With its local service and the companies in which it is interested, it controls 15,000 telephones.

The new automatic system is installed under the Strowger patents, by the Automatic Electric Company, of Chicago. The contract for the system was entered into in December, 1902, and last May the erection of a new exchange building was begun, which was completed in November. It is centrally located, not far from the site of the old exchange, and is a model telephone building in every respect. The work of installing the automatic apparatus and connecting the exchange lines through the new system instead of directly to the old was taken up at once and hurried along by a large staff of electrical workers with no delay.

As already stated, the Grand Rapids automatic exchange is the largest in the world as regards the number of telephones in service. The New Bedford and Fall River, Mass., exchanges, the first installed in this country, are operating respectively with 1,400 and 800 subscribers. An exchange at Dayton, Ohio, opened recently with 2,800 subscribers, and one in Chicago with an ultimate capacity of 10,000 subscribers is now operating with about 3,000, while there are a few smaller exchanges in various parts of the country. But Grand Rapids cut in 5,300 telephones, including instruments on party lines and those in outlying districts accommodated on a "rural switchboard."

The new exchange building is a handsome structure of red brick with stone trimmings, 68 by 143 ft. in dimensions, and two stories high, with a finished basement that makes it practically a 3-story building. The basement is of masonry, finished in cement and provided with cement floor. It is divided into a large supply room and a furnace room, and out of it opens the tunnel through which the cables enter the building. The tunnel is a remarkable piece of subterranean engineering work. Many feet under the ground it stretches from the basement to a point 250 ft. distant where is located the manhole in which the extensive conduit system terminates. It is 7 ft. in height and nearly 5 feet in width. Along the walls are carried 36 permanent cables, each of 200 to 400 pairs of conductors. The tunnel is electrically lighted and a switch at the basement entrance controls the illumination.

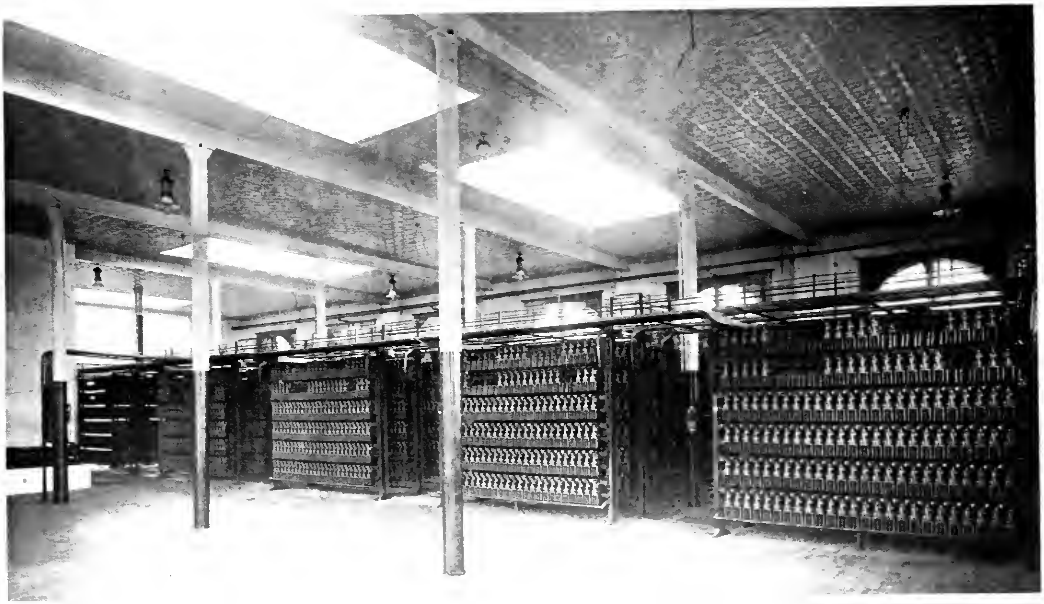

FIG. 1.—INTERIOR OF SWITCH ROOM, GRAND RAPIDS EXCHANGE.

The first floor of the exchange building is given over to the general offices, private offices of the company officials, draughtsmen and electricians, and to a spacious repair shop in the rear. The offices are fitted throughout in antique oak with white finished walls, and the general offices directly in front of the main entrance are equipped with furniture of the bank variety. Everything is of a modern and practical type and convenience appears to have been the keynote in its selection. The shop in the rear is a large room equipped with machine tools, work benches, and the various appliances and accessories with which machinists carpenters and electricians work. The company does not only its own repair work, but that of the smaller exchanges on its toll lines; and a large staff of repair men is employed. The stairway leading to the floor above is convenient to all the departments down stairs, and also opens upon a side entrance to the building for the use of the toll room operators and others employed on the second floor. The latter floor is apportioned to the exchange or switch room, the toll operating room, women employees' club rooms and inspectors' room. The stairway on this floor opens upon a long corridor which separates the switch-room from the other deaprtments.

Entering the switch-room, one confronts the desk of the wire chief,

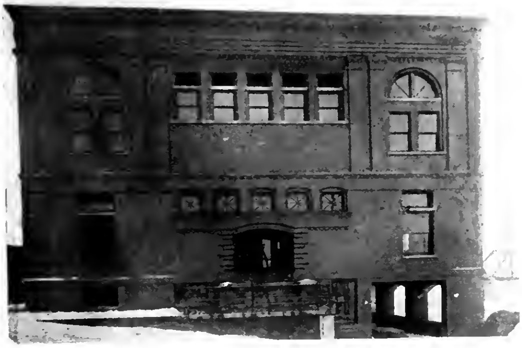

FIG. 2.—EXTERIOR OF EXCHANGE BUILDING.

who is the head "trouble man." At one end of his desk is a small window which opens into the inspectors' waiting room, the convenience of which arrangement is obvious. Near by is the main distributing board, reached on one side by the cables from the tunnel and on the other by the switch-room cables. It is a board of the most modern design, and the terminals are arranged in such a compact way that it is only 10 ft. in height and about 12 ft. in width. It is made in sections, and its ultimate capacity is practically unlimited.

The small cables from this board do not lead directly to the banks of automatic selector switches, but first cross the hall to the tool line operating room, where thew are tapped upon the toll room exchange switchboard. Again they cross the hall to the switch room and find their way to the subscribers' selectors. Here are provided five banks or frames of selector switches, or selectors, with 1,000 to each bank,

FIG. 3.—TOLL LINE OPERATING ROOM.

and additional ones known as trunk selectors. The frames are of heavy angle iron and hardwood. The lower four rows or 100 selectors, and the upper ones are the trunking selectors. Of course, in the Grand Rapids exchange, as in any automatic exchange having more than 999 telephones and consequently having numbers of four digits, two sets of trunking selectors are necessary. There is ample floor space for at least three more banks of 1,000 selectors, so that the exchange has a capacity of 8,000 telephones, and by the removal of some partitions even this could be increased.

Just in front of the main distributing board and between it and the selector banks is the generating plant with its switchboard. One generator is provided to charge the storage batteries used in the toll service, the motor side operating on the Edison 220-volt circuit.

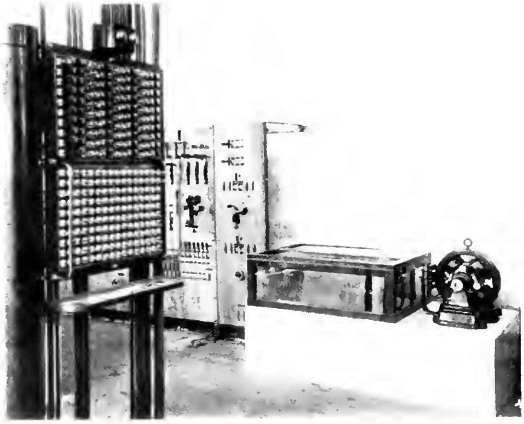

FIG. 4.—AUTOMATIC TELL-TALE BOARD AND CURRENT INTERRUPTERS.

Two other rotary converters are provided for charging the storage battery plant that operates the selectors. In addition to these, two sets of motors and generators provide the alternating current for the magneto bells, and a third of similar style but smaller is provided for the night service. An important piece of apparatus in this department is the interrupter and its reserve duplicate. These are

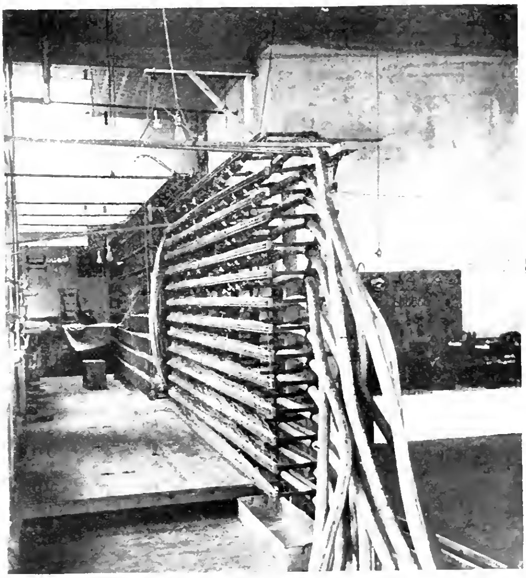

FIG. 5.—TEMPORARY WORK TO FACILITATE THE CUT-OVER.

contained in a glass case, and are revolving commutators of special design that furnish the intermitting or pulsating storage battery current that operates the rotating, trunk-selecting arms of the selector switches. The interruptors contain also a device which produces the current that gives the "busy" test, or "busy buzz," as it is called. Small electric motors revolve the commutators of these interrupting machines. A handsome marble panel switchboard is provided nearby upon which are mounted the switches, volt- and ampere-meters, lightning arresters and other accessories of the generating plant. A "tell-tale" board stands not far distant from this, upon which are miniature lamps and a magneto bell to detect and locate grounded lines. At a glance the switch room employees can tell in what set of 100 selectors one may be found in which the delicate protector fuse is blown.

Across the hall is the toll room, one of the prettiest departments of the whole plant. Here are switchboards for a variety of purposes. The contract for this apparatus was placed through the Automatic Company, but the switchboards were manufactured by the Kellogg Switchboard Company. First in the line is the exchange switchboard, upon which is spread out a system of contacts representing the entire city exchange. Adjoining this are three recording operators' positions, and next to that is the "through" board, on which one toll line is connected with another. Continuing down the side of the room from the "through" board are ten toll operators' switchboards, upon which the toll lines come in. Calls from outside come over these, and are "trunked" to the main exchange switchboard, where the subscriber is called. On the other hand, calls from subscribers for toll lines are received at the recording operators' boards, recorded, and trunked to the toll line boards. The telephone instruments in use are provided with calling dials that have finger-holes not only from 0 to 9, but an additional one for "long distance." A turn of the dial to this point gives a connection with one of the recording operators' boards. It is the first time the Automatic people have installed telephones provided with this special long distance call.

At the end of this toll room is the "rural board." This is provided to accommodate subscribers located in the outlying districts or a long distance from the exchange. It appears that the automatic service does not operate so well over very long circuits, and a complete automatic system in a large city would mean a number of branch exchanges with trunking systems. The board has a capacity of 132 rural subscribers, but there are not nearly that many located so far away from the central exchange that they lose the advantage of the automatic service. These few have "Rural 25" or "Rural 30," or some other number affixed to their regular number in the directory, and their service is in part through this board.

In addition to this array of switchboards, the toll room is provided with three large double desks arranged to accommodate six persons. They are the positions of the toll traffic manager and five information clerks.

Adjacent to the toll room is a locker room for the young women employees, in which are provided black enameled lockers of expended metal. It may be noted at this point that lockers of the same style are provided in the inspectors' room and in the shops and offices. Passing through the women's locker room one reaches a beautiful suite of rooms elaborately furnished and fitted out as club rooms for the women employes of the company. A reception and dining room are finished with woodwork of dull black oak and walls of rich green. The walls are hung with pictures of high colored poster style, framed to match the finish of the room, and polished wood floors are covered with rich rugs. The furniture is of dull black oak, and is of the quaint and artistic design so popular for "dens," beer rooms and the like. Some of it is richly upholstered with leather cushions. Handsome electric chandeliers and fixtures of odd design match the general effect. The dining room is provided with a china closet well supplied with china and cut glass, and just off this room is a kitchen with its pantry and a large gas range. It is the plan of the company to keep the canisters of the pantry filled with tea, coffee and other beverages, and a matron will be in charge of this department.

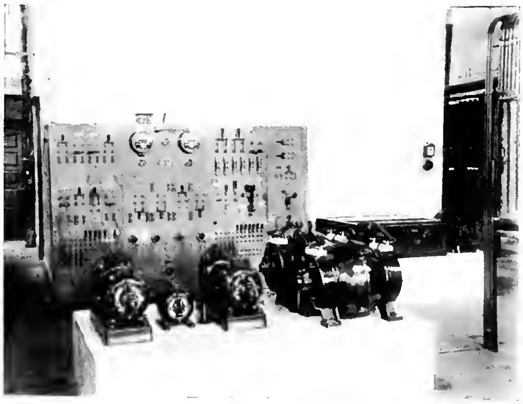

FIG. 6.—GENERATING APPARATUS AND SWITCHBOARD.

The method by which the inauguration of the new system was effected and the "cut-over" made in the short space of seven minutes, is quite interesting. For some weeks prior to the "cut-over," Citizen's telephone users had been talking through the new exchange, although not using it. The conductors of the necessary number of temporary cables were tapped to the terminals of the main distributing board in the new exchange. These cables were conducted through the tunnel and a temporary conduit system to the old exchange. The terminals of the new distributing board are provided with spring contacts that may be separated by the insertion of an ordinary wooden toothpick, and this was done. Thousands of toothpicks were arranged in these terminals. When the "cut-over" was made the toothpicks were withdrawn and the temporary wires to the old exchange were cut off.

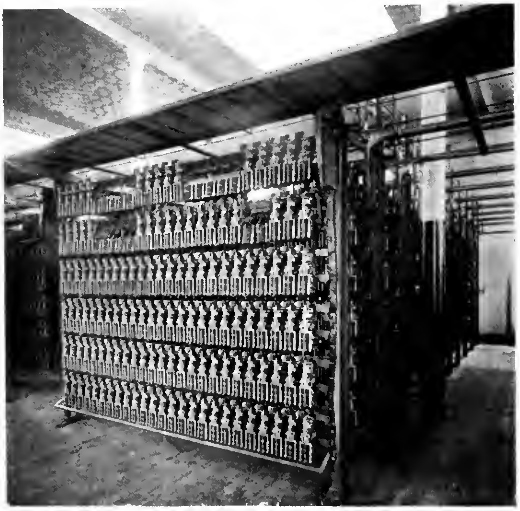

FIG. 7.—ONE OF THE BANKS OF SELECTOR SWITCHES.

Grand Rapids had long been waiting for the new system and it seems that most of the subscribers were at their telephones waiting to try them as soon as the system was switched in, which it was announced would be at 12:30 sharp. Fifteen minutes after the system was cut in, General Superintendent Keith, of the Automatic Company, estimated that 1,700 switches existed or twice that many telephones were in use, simultaneously, out of approximately 5,000 lines connected to selectors. The largest number of simultaneous connections that was ever counted in the old exchange was 204. For the few days that have elapsed since the inauguration of the automatic service it had worked splendidly, and Grand Rapids telephone users have nothing but words of praise for it. Officials of the local company say the "trouble" is not nearly what was expected and what had been provided for, and that it amounted, even during the first two or three days, to little more than the normal under the old system. Some difficulty comes from the fact that many numbers—about 1,200—were changed; four digits are necessary to each automatic number, to insure four turns of the calling dial, and 5,000 was added to all the old numbers from 1 to 999. Some other numbers were altered for various reasons.

The new telephone exchange building cost the company $60,000. The cost of the automatic exchange and apparatus is not given out by the officials, but it is believed by some competent to judge that the price approximated $200,000.

FIG. 1.—EAST END AND NORTH FAÇADE, PALACE OF MACHINERY.

The Westinghouse Service Plant at the St. Louis Exposition.

Although a large amount of power for the use of the Louisiana Purchase Exposition will be derived from exhibition apparatus in Machinery Building, with boilers located in the Steam and Fuels Building, near by, it was decided by the Exposition authorities that it would be best for the Exposition to erect under contract a service power plant for the use of the Exposition, which would be more directly under the control of the Department of Works than exhibit apparatus could be. Such a plant is needed for the service of the Exposition, and it is essential that it should be completed and in operation before the Exposition opened without any of the uncertainties attending the completion of exhibits. It was finally decided to award the contract for such a plant, with a capacity of 8,000 kw, to the Westinghouse Electric & Manufacturing Company. This contract covers the entire power plant equipment with the exception of the buildings and stacks. The engines and generators will be placed in Machinery Hall in a space set aside for the service plant. The boilers will be located in the Steam and Fuels Building, 100 ft. distant, which is the building in which all boilers and gas-producing apparatus will be placed.

Although this is a service plant in name, it will, of course, be an interesting exhibit. While there will be nothing radically new in its essential elements, it will represent good modern power house engineering practice. The reasons urged for the award of this contract to the Westinghouse Electric & Manufacturing Company were that, on account of the many allied Westinghouse interests, it would be possible for this company to handle a large part of the contract without going outside of the Westinghouse companies and chances for coherent design and prompt completion were better than if the contract were awarded to several companies. Thus, the steam engines will be furnished by the Westinghouse Machine Company, and the engineering and construction of the plant will be done under the supervision of Westinghouse, Church, Kerr & Co. The plant will contain four units of 2,000 kw each. These will be 25-cycle, three-phase, 6,600-volt generators, direct-connected to Westinghouse Corliss engines. The generators will weigh, without the bed, 132,000 pounds, and with the bed 190,000 pounds. The efficiency guarantee is 96 per cent. at full load, 95 per cent. at three-fourths load, and 93 per cent. at one-half load. They will operate at continuous full load with not over 35° C. rise in temperature. The engines will be Westinghouse vertical, cross-compound, condensing, Corliss, running 83 r.p.m. They are rated at 2,800 hp and have a maximum overload capacity of 5,200 hp, the latter capacity being reached at three-fourths cut-off in the low-pressure cylinder. The cylinder diameters are 38 and 76 in., with 54-in. stroke. The shaft will be hollow forged steel 31 in. in diameter. In addition to the fields of the generators, the engine will have a fly-wheel of 175,000 pounds weight. The total weight of the engine is 750,000 pounds. It is guaranteed to operate on $13\frac{1}{2}$ pounds of steam per indicated hp-hour. Water for condensation will be supplied from a cooling tower having fans driven by electric motors, to furnish air circulation.

The boilers in the Steam and Fuels Building which will supply this plant are 16 in number, of 500 hp each, of the B. & W. water tube type. Smoke flues will be placed under the floor and led to the stacks built by the Exposition. In addition to the natural draft, fans will be installed to produce artificial draft when needed, in accordance with Westinghouse practice. Roney mechanical stokers will be used under these boilers. That part of the Machinery Building devoted to the service power plant is spanned by a 40-ton traveling crane. Besides the main units, there will be three 80-kw exciter units, any one of which is sufficient for the entire power plant. These units will be direct-connected to vertical cross-compound, condensing, West-

FIG. 2.—INTERIOR OF MAIN ENTRANCE, PALACE OF MACHINERY.

inghouse engines running 300 r.p.m. The weight of a unit complete is 38,000 pounds.

A Westinghouse switchboard will be installed consisting of three exciter panels, four generator panels, two main load panels, two incoming feeder panels and twenty-four outgoing feeder panels. The incoming feeder panels are for the current which is to be purchased by the Exposition from the Union Electric Light & Power Company.

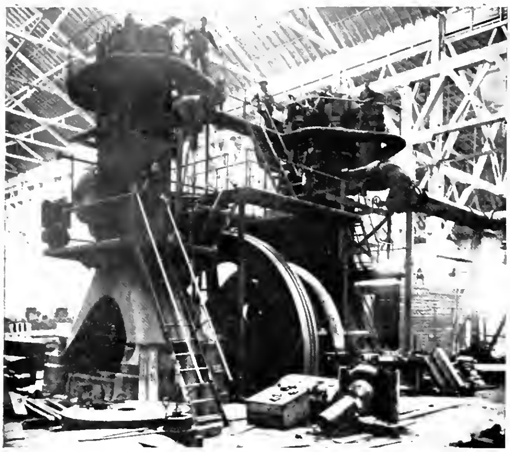

FIG. 3.—2,000-KW DIRECT-CONNECTED GENERATOR, PALACE OF MACHINERY.

The two load panels will pass the entire load, one panel being used for each of the two sets of bus-bars. Solenoid-operated oil switches are to be used for the high-tension alternating current, and these will be controlled in the usual manner by low-tension circuit, with switch handles on the various panels. On each generator panel will be three switches, one controlling an oil switch connecting the generator with one set of bus-bars, the other connecting it with the

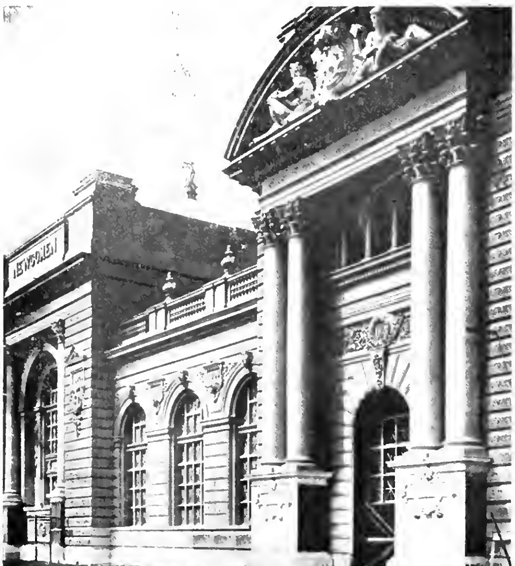

FIG. 4.—PORTION OF FAÇADE, NORTHEAST ENTRANCE, PALACE OF MACHINERY.

other set of bus-bars, the third being in the generator leads in series with the two just mentioned. The switches will be equipped with time limit release for automatically opening the circuit. Each generator panel will have one power factor indicator and three ammeters. Each feeder panel will have three oil switches, two of which are in multiple for connecting to either set of bus-bars, and the third in series with the other two, or the reverse of the generator switching arrangement. Each feeder panel will have also three ammeters and one integrating wattmeter.

Although not a part of the service plant, another interesting contract which this company is filling for the operation of the Exposition is for the 2,000-hp induction motors to be direct-connected to Worthington centrifugal pumps, to supply the Cascades with 90,000 gallons of water per minute. Thhs will be a remarkable installation, not only on account of the size of the induction motors, but on account of the size of the pumps and the high head to which water must be raised, which is approximately 150 ft.

Recent Electrochemical Developments.

FURNACE INVENTIONS.

There is great activity at present in resistance furnace design with an intention to obtain a perfect regulation of temperature and a uniform heating effect. This development is combined with a tendency to apply the electric furnace to processes requiring relatively lower temperatures than heretofore. This means an extension of the use of the electric furnace which was formerly restricted to the production of extremely high temperatures. An example of this development is a method of making carbon articles for which a patent was granted on January 12 to Mr. E. G. Acheson, of Niagara Falls. In manufacturing carbon articles, the customary method is to take some suitable carbon—such, for instance, as ordinary coke, coke produced from petroleum, or lampblack—in a finely subdivided form and mixed with tar or another appropriate binding material and moulded under pressure into the desired forms. These forms are then placed in a gas or coal-heated furnace and slowly raised in temperature until all of the contained volatile hydrocarbons have been driven off, leaving the articles in a solid, dense and coherent condition, for use as electric light points, electrodes, dynamo brushes, etc. In the last step of this process, as the articles are massed together in large volume, much time is reqnired for their efficient packing and considerable difficulty is encountered in obtaining a uniform elevation of temperature throughout the several articles, and the failure to do so frequently results in serious warping or cracking of the goods treated.

Mr. Acheson designs his electric furnace in such a way as to produce a uniform elevation of temperature throughout the mass of the carbon article. In his furnace he is also able to attain a considerably higher temperature than can be obtained in a gas or coal-heated furnace, so that while he does not reach the temperature required for changing the carbon into graphite, yet the temperature is sufficiently high so as to polymerize the carbon and increase its density, electric conductivity and resistance to chemical action. The carbon articles are embedded in a resistance material of granular carbon or a mixture of granular carbon and silicon, etc. The carbon articles to be heated are placed with their longest diameters at right angles to the flow of the current. The intention is not to produce heat in the carbon articles as the result of passing the current through the articles, but rather to produce the heat in the packing material separating the carbon articles. The result is a very uniform raise of temperature.

Three patents have been granted to Messrs. Le Roy W. Stevens and Bernard Timmerman, of Chicago, for an electric furnace for making carbide or the like. The invention contemplates essentially a down-draft furnace in which the falling material is preliminarily heated, the resultant gases being drawn off at a high temperature and used for any desired purpose, an auxiliary chamber into which the material is charged and again treated, the resulting gases from this second treatment being conducted to the main flue, and delivered therein near its top at a high temperature, increasing the temperature and the chemical reaction.

STORAGE BATTERY ELECTRODE.

A patent was granted to Mr. R. Hager, of Halensee, Germany, for a Planté electrode, comprising separate plates coaxially arranged. Each plate is composed of a series of channel-shaped plates arranged one above the other. Each channel-shaped plate is provided with a slit extending transversely of the channel. The object is to prevent injurious tensions being set up during charging and discharging which would cause the active material to break off.

Institute Meeting in Chicago on Storage Batteries.

The Institute meeting held January 12 in Chicago was presided over by President Arnold. Mr. Lamar Lyndon's paper on "The Comparative Behavior of Floating and Booster-Controlled Batteries on Fluctuating Loads," presented at the November meeting in New York, was abstracted by Mr. J. M. S. Waring, of Chicago. The discussion was participated in by a number of storage battery men and served to show the value of a storage battery, not merely from an engineering standpoint, but as an investment as well. Commercial utility was the keynote of the discussion.

President Arnold, in introducing the first speaker, called attention to the wonderful strides made in storage battery engineering in the last eight or ten years and the recognized place the storage battery now occupies. Mr. George Damon, managing engineer of the Arnold Electric Power Station Company, described two installations which have been made by him. The beneficial effect on operation of electric roads was clearly proved and the investment under such conditions shown to be about the same as if no battery had been installed. Mr. Joseph Appleton, manager of construction of the Electric Storage Battery Company, considered the best methods of operating batteries to give results which will yield the best return on the investment, or, in other words, the maximum commercial efficiency. The battery which does the most work is not always the one which gives the greatest commercial efficiency. Continuing, he stated the conditions under which a battery for a railway system may be installed, to be as follows: Increase of capacity of the generating plant; evening up the load on the generator plant to give greater economy of operation; saving of copper and maintaining proper potential on the line.

It depends largely for which of these purposes a battery is installed, as to where it should be located, and how it should be controlled. In addition to this, the location of the battery will depend a great deal on the price of real estate and cost of attendance. All of these things must be taken into consideration before it can be decided where to place the battery. It should also be determined what proportion of the total load the battery should take; this will be governed entirely by local conditions. For example:

Where a generator plant is operated by steam, the capacity of the boilers and units should be taken into consideration, or where current is purchased from a large system, operated by either steam or water power, the terms of the contract under which the power is bought will frequently determine what the battery should do. To illustrate what is meant, two cases were mentioned. One is the Inter Urban Road between Seattle and Tacoma, which is operated from four sub-stations, the power being bought under contract from the Snoqualmie Falls Power Company. In each of the sub-stations there are two motor-generators, of 300-kw capacity; each one of these with the battery in each sub-station is sufficient to run the load under ordinary conditions. The economical maximum load on each of these stations, according to the terms of the contract, is about 600 amp., the actual load varying from 200 to about 1,800 amp. The batteries and boosters in these stations are so adjusted that the battery will not discharge to any extent, until the load on the generator reaches 600 amp., after which point the battery and booster practically take the additional load. These conditions naturally do not show a very good load curve as far as the battery is concerned, but yet it is working under maximum commercial efficiency.

An illustration of the opposite condition can be found in the plant of the Oakland Transit Company, which operates a system of five car trains, running to a ferry, landing in Oakland from San Francisco. In this case the load on the station varies from zero to 2,600 amp. and by the use of the battery and booster the system can be operated by one 600-kw steam-driven generator, the load on which is maintained between 800 to 900 amp. all the time. These two plants illustrate clearly the operation of a battery where close regulation is advisable, and also where it does not pay to get close regulation.

In these days when electric railways are extending so rapidly and the growth of interurban service is so marked, new conditions are arising for the power plants and sub-stations operating such systems. We find two kinds of fluctuations, one due to the local service, where the fluctuations are frequent and comparatively small, and one due to interurban service where the fluctuations are periodical and very great. In such a case it does not pay to adjust the battery and booster to take all the small fluctuations, for if this was done a battery large enough to take all the heavy fluctuations due to the interurban service would mean too great an investment to be profitable.

The average load on such stations is usually more than the local service load, and therefore a portion of the interurban fluctuations can be safely and economically carried by the power house or the sub-stations. The battery, in this case, gives its best results commercially by taking that part of the load which would overload the sub-station too heavily. The rapid growth of interurban service means a greater use of batteries, as without them it is necessary to install generator machinery sufficient to carry the maximum interurban load, while the average is very much less. Generally speaking, if the battery is to relieve the station of fluctuations, it should be located at the station, and if it is to save copper or maintain proper voltage on the line, the battery should be located out on the line.

Each year finds the use of storage batteries increasing very rapidly, and this is due largely to the fact that the proper use and operation of a storage battery which gives the maximum return for the investment, is being understood. The life of a storage battery is practically proportional to the number of kilowatt-hours taken out of it, and consequently the maintenance of the battery can be kept down to a minimum, by only using the storage battery to take part of the load which pays. In other words, by using the battery to give the maximum efficiency of the combined system, and not merely to straighten out the load curve irrespective of the cost of current at different times and under various conditions.

Mr. John. I. Beggs, of Milwaukee, emphasized the commercial aspect of the subject. He heartily concurred in Mr. Appleton's statements and considered that the storage battery has often suffered because it has not always been installed with a view to best meet existing conditions. Mr. Beggs stated that he had been forced to install a battery at Milwaukee a few years ago because of the advent of the steam turbine at a time when he was considering making an investment of $4,000,000 for a new power house. The conditions under which the battery had been installed were severe inasmuch as it had to be used either for street railway work or on an Edison three-wire system, or both at once. The battery had proved of inestimable value and an actual necessity, although the price would lead one to believe it to be a luxury.

Mr. Ernest Lunn, of the Chicago Edison Company, in discussing Mr. Lyndon's paper, considered the storage battery more especially from the operator's standpoint. He said that it would be interesting to know to what extent changes affect the behavior of a battery since its characteristic changes with age, with variations of temperature, specific gravity, and condition of plates. The facts might be different in the case of a battery floating near a station from that at the end of a long feeder. A rise in temperature would cause the battery characteristic to approach the horizontal line and the battery would give a greater discharge for a given drop in pressure than if the temperature remained constant. The characteristic with most batteries would likewise gradually approach the horizontal as the battery ages, further increasing the charge and discharge for variations in line pressure. In discussing Mr. Lyndon's statement that "In any battery used for regulation, it is necessary that the input approximately equal the output, otherwise the state of battery charge is changed and the efficiency of the regulation decreased," he stated that it was quite necessary to have about ¾ full charge if the best results from the battery are to be expected, or at least to have some fixed state of charge. A battery at ¾ full charge will discharge at a higher rate for the same drop in pressure than it will at, say, either full charge or half charge. It is of importance then to be able to adjust the voltage and load, so that the battery may be in condition to float at the proper point of charge, else the desired results will not be obtained, due to the change in the battery characteristic. Batteries, too, are not all alike in regard to initial and final voltage; especially is this true of batteries of different manufacture. Some means, therefore, to compensate for irregularities and unavoidable variations should be provided.

The second feature of the evening was the paper on "Gas Power for Central Stations," by Mr. J. R. Bibbins, an abstract of the paper being read by the author himself. Mr. John I. Beggs, in opening the discussion, stated that personally he was more especially interested in what had been accomplished in the way of large gas engine units. As compared with steam engines of small size, as usually operated, the gas engine no doubt is far more economical, and he was ready to concede all that was claimed for it, and more, too. The units and results considered in the paper, however, were not such as to admit of predicting what these would be with, say, 5,000-hp units. When a company must sell current for as low a price as 1 cent per kilowatt-hour at the switchboard, small units, whether of the reciprocating steam engine or the gas engine, are out of the question. There was a question in his mind as to whether the steam turbine or the gas engine will eventually prove the more economical. Three or four years ago he had, as already stated, delayed the building of a power house to cost $4,000,000, as the steam turbine was then looming up. Now he was disposed to further delay action on account of the advent of the gas engine. He had received a proposition to install a 5,000-hp gas engine, a size to be considered. The men in charge of the financial operation of great properties had to contend with not only such problems, but others as well. Milwaukee is seeing the building of a coke oven plant which will turn out fuel gas as a by-product. The competition which such an enterprise will develop may prove serious, and there is a question in his mind whether it would not be profitable to buy the entire output of the plant for a gas engine power plant.

Mr. George N. Eastman, of the testing laboratories of the Chicago Edison Company, compared the efficiencies of the various prime-movers emphasizing the greater economy of internal combustion engines. Mr. C. E. Sargent outlined the development of the gas engine and ascribed the lack of greater progress to the fact that the original patents had expired but recently. With the double-acting tandem horizontal engines now being put on the market, a uniform turning moment is obtained and a regulation as good as with the steam engine. Mr. W. L. Abbott, chief operating engineer of the Chicago Edison Company, predicted that if gas engine development in the next three years would be as rapid as that of the turbine in the same length of time, a great deal would be accomplished. He pointed out that whereas the steam turbine had been known for 2,000 years, the gas engine was a product of the last twenty years. Mr. C. H. Williams gave the result of his experience with small gas engine units at Madison, Wis. Mr. Bibbins, in concluding the discussion, made the point that if the showing in the case of small gas engine units is good, it is safe to say that large units will do as well if not better. He ascribed the lack of development in the past as due to a great extent to the lack of an improved gas producer. The question as to the relative value of the gas engine and the steam turbine was in reality foreign to the subject of his paper. In fact, the prime-mover should be chosen with a view to its suitability for any given set of conditions.

The meeting was one which showed the Chicago membership well alive to the subjects considered, and it was well attended. The next meeting will be held February 2 and will be devoted to a discussion of the important question of manual versus automatic telephone operation. Mr. Frank Dommerque will present a paper on "Commercial Aspect of an Automatic Telephone Exchange."

General Electric Foremen's Banquet.

The Foremen's Association of the General Electric Company held its second annual banquet at the Edison Hotel, Schenectady, N. Y., on the evening of January 9. At the conclusion of the dinner Mr. T. E. Leavitt, president of the association and toastmaster, called upon several gentlemen present to respond to toasts. Mr. E. W. Rice, vice-president of the General Electric Company, took as his theme "The General Electric Company at Home and Abroad." He referred to the history of the joint companies of the plant, mentioning the pioneer enterprise such as the Edison works and giving an idea of what each contributed to the work done by the larger plant. He also told of the work done by the branches in the other parts of the world, such as Japan, Egypt and India.

He delved into statistics and said that if all the buildings of the General Electric Company in the United States were joined in one structure 50 ft. in width they would extend from Schenectady to Albany, 18 miles. He further stated that the company employed between 18,000 and 20,000 men in the different works throughout the United States.

On the subject of incandescent lamps manufactured by the company in the last 10 or 12 years, he stated that no less than 125,000,000 had been turned out. To show that the stockholders of the company were not taking in all the profits made by the works, Mr. Rice said that the immense sum of $75,000,000 had been paid to their employees in the United States within the last 12 years, while the stockholders had received $15,000,000, but one-fifth of that sum, during the same time.

Mr. G. E. Emmons, general manager of the works, was next called upon and gave a retrospection on the company's work during the last year. He said:

"The business of 1903 was greater than that of 1902. This was due, however, to the fact that a number of old contracts were carried over, as the current orders received were not as great as in 1902. From the indications it looks as if the business would be light for the next few months, but will probably soon pick up."

He thanked the men for their efforts, giving them much credit and attributed much of the good showing made by the company to the work done by the foremen.

"During 1903," he said, "we spent much for new and improved machinery, for it is the policy of the company to do so whenever it is shown that it can thereby lessen the cost of production. Competition is very strong and in order to keep in the flock and lead competition, it is necessary to be constantly employed in introducing improved methods, improved machinery and any other change that would tend to lessen the cost of the output. Watch closely for economy, but remember it is economy to spend freely when a saving can thereby be effected."

"Electricity as Applied to Machine Tools" was the topic of Mr. A. L. Rohrer, superintendent of electrical construction. "At present," he said, "we have about 6,000 machine tools in the works, run by 900 motors. Six hundred and eighty-seven of these are driven by individual motors. In 1900 we had but 460 motors and even since 1902 the increase in our power is fully 30 per cent." In speaking of the arc lights which are used in the plant, Mr. Rohrer stated that no less than 2,000 of them were in use, fully as many as are employed to light an entire city of 300,000 people.

Among the other speakers who were called upon were E. B. Raymond, foreman of the testing department, who spoke upon "The General Utility of Electricity as Applied to Modern Industries"; J. Riddell, who addressed the men on "High Speed"; L. Gibson, superintendent of the producing department, and B. Morrow, foreman of the testing department, whose subject was "What I Know About Water."

Radium Mines in London.

A cable dispatch from London says: "The possibility is suggested that London may become the center of a peculiar mining industry. There are houses somewhere within the metropolitan area whose foundations are imbedded in a precious substance, which, if it could be recovered, would be worth more than a whole street of houses. The very roads along which London's unwitting millions hurry about their daily business lie on artificial beds of radium, put down many years before the nature or value of the element was discovered. Sir William Ramsay is authority for the statement that a London firm of analytical chemists has thrown away for many years the by-products obtainable from pitchblende in the process of extracting uranium. The firm which thus unknowingly has flung probably many great fortunes to the wind is Johnson, Matthey & Co., Limited, of Hatton Garden, but, as one of the principals remarked the other day, radium had not been discovered at that time. "As a matter of fact," he added, "we actually paid, I believe, three shillings and sixpence a ton to have the stuff carried away in dust carts. It was used for leveling and laying out roads in the city and for filling in the foundations of houses." For twenty-five years the firm was engaged in extracting oxide uranium from pitchblende. The oxide was used mainly to color expensive glassware, to which it gave a yellowish-green fluorescent appearance. The use of uranium for this purpose has been long discontinued in favor of cheaper methods. Much of the pitchblende worked upon by Johnson, Matthey & Co. was obtained from the mines at Joachimsthal, Austria."

Wireless Telegraph on the Pacific.

A special dispatch from San Francisco says: "Apparatus for wireless telegraphy has been installed at Point Reyes, forty miles north of San Francisco, on the coast line, and on the southeast of Farallon Island, which works perfectly. Prof. Alexander G. McAdie, in charge of the local branch of the United States Weather Bureau, assisted by Alfred H. Triessen, the government wireless telegraph expert, installed the plant."

Curious Action of Static Charge.

We are indebted to Mr. Fred R. Cutcheon, superintendent of the electrical department of the St. Paul Gas Light Company, for the following item and the photograph which accompanied it:

I enclose herewith a photograph of a peculiar electrical phenomenon; it was taken from the inside surface of a hard rubber box upon which was mounted a choke coil, of 28 turns, this choke coil being located at the point where our 25,000-volt overhead line, 30 miles in length, passes into an underground cable. Ordinarily, the drop

CURIOUS ELECTRICAL EFFECT.

over this coil is only a fraction of a volt, and the photograph shows what an enormous resistance the coil must offer to heavy static charges. The actual distance between the terminals is 9 in. The white appearance of the rubber is due to a white sooty deposit; the black radiating lines are charred rubber, which is raised up in ridges about ⅛ in. high.

There was no evidence of any discharge between lines. This same phenomenon occurred on all of the six choke coils, and was observed to a less extent on coils of the same make at the generating end of the line. The photograph was taken by Mr. George B. Overton.

New Telephone Patents.

TELEPHONE REPEATER.

A modification of the telephone microphone repeater has recently appeared which attracts attention because of the particularly ingenious arrangement of its various component parts. As may be seen from Fig. 1, a single diaphragm serves for both telephone and microphone parts, while the coil, *I*, shown inclined to the horizontal also serves a double function, viz., as induction coil and as receiver coil. The transmitter button, *c*, contacts with the diaphragm through three small contact joints and thus it follows any motion of it. The diaphragm in turn receives its motion under the magnetic influence of the induction coil core, which has a permanent polarization under the influence of its primary coil and a varying magnetization under influence of the secondary coils, one of these being in each of the circuits to be interlinked. The letters, *X* and *Z*, indicate the two widely distant stations which are to communicate through the repeater, while *T R* is a supervisory station connected in the primary circuit. This repeater is the invention of Merritt Gally, of Brooklyn, N. Y.

RINGING FACILITIES.

With "two-wire" central energy switchboards of some kinds, the energization of a so-called cut-off relay serves to maintain the only connection between the subscriber's station and the switchboard jacks. The coil of this relay is bridged across the jack and it receives its actuating current from the central battery through the cord circuit. Now, when an attempt to ring the subscriber is made, as the ringing key serves the cord circuit and disrupts, therefore, the connection between the battery and relay, this latter falls back and opens the line, thus defeating the ringing, unless some special arrangement is made to prevent. One such arrangement is that recently patented by A. D. T. Libby, of Chicago, which provides an extra outside contact for his ringing key, from which a connection is made to the battery, a retardation coil being included in the circuit. This connection provides a constant battery supply during ringing, while the presence of the retardation coil renders the circuit impervious to the ringing current. Mr. Libby has assigned his patent to the Kellogg Switchboard & Supply Company.

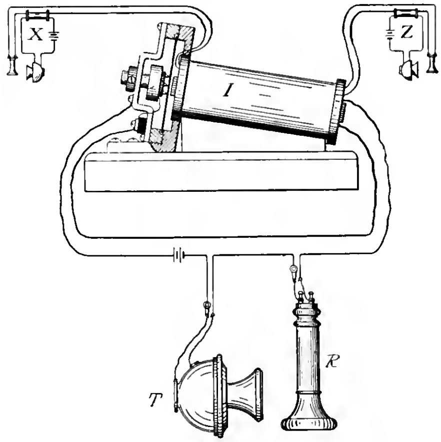

FIG. 1.—GALLY TELEPHONE REPEATER.

A second patent relating to ringing describes a new type of ringing key, which has been designed by W. Meyer, of Chicago. This key, which combines both ringing and "listening-in" is of the lever type, the most novel feature being the bending of the upper end of the contact springs on the "listening-in" side of the key in a manner such that when the lever is thrown, their pressure is normal to the lever pivot, and thus the lever remains in the thrown position in this direction without the use of auxiliary devices. The Stromberg-Carlson Company has obtained by assignment the patent for this key.

A SWINGING TELEPHONE SUPPORT.

Some years ago a few telephone companies produced a swiveled desk telephone, which, while supported at the side of a desk, could be swung over its top without the user being annoyed by the entanglement of the flexible cords with papers, etc., upon the desk. Recently almost none of these have been put into service, and, therefore, the telephone support, which has been patented by C. H. Pelton and W. Ramsey, of Springfield, Ohio, and which seems to provide

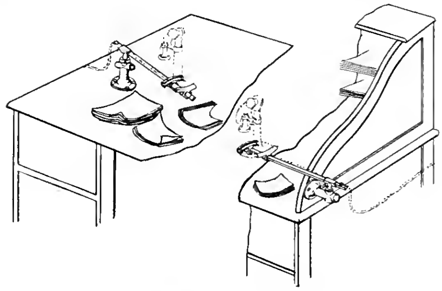

FIG. 2.—PELTON AND RAMSEY TELEPHONE SUPPORT.

all the features of the old swinging arms, should "fill a long-felt want." Fig. 2 shows the support applied to two desks and indicates the principles as well as could any further description.

TELEPHONE LOCK.

A new variety of telephone lock has been patented by S. J. Larned and J. S. Ford. This lock is to serve for the protection of the telephone company rather than for that of the subscriber, as it is to be used to lock a telephone from service in case of non-payment. A bolt or block is designed to fill the escutcheon above the switch hook, being held in place by a hasp hinged thereto and threaded through the rings now customary upon the ends of the prongs of switchboards. The hasp is then secured by a padlock. The lock not only holds the hook in the depressed position, but prevents the removal of the receiver from the hook. The American Telephone & Telegraph Company have been assigned this patent.

REVERSE-CURRENT TRANSMITTER.

Phillip G. Randall, of Boston, is the patentee of a transmitter designed to cause actual reversals of current in the primary of its associated induction coil. The diaphragm is a stiff plate of carbon suspended in spring clamps engaging its periphery. The vibrating air impinging on the diaphragm causes its movement as a whole. Opposed to either face of the diaphragm are several microphone buttons mounted upon springs. All of these buttons upon one face are associated in one part of the circuit, while those upon the other face are associated in another group. These two groups of buttons are then so connected to the circuits and batteries and induction coil that the combined effect of the whole apparatus is an alternating indulatory primary current.

STEP-BY-STEP PARTY LINE SELECTORS.

Two selective party line systems, both depending for selection upon switches moved by steps under the influence of current impulses in an electromagnet are described in patents of last week's issue. Of these one requires three line conductors, while the other uses the ground in lieu of one of these for both the ringing and talking circuits. Messrs. F. A. Lunquist and J. K. Norstum are the patentees of this latter, while the former is the joint invention of Messrs. H. Redmon, R. L. Hall and R. H. Conway.

Marconi Wireless Telegraph Work.

Mr. John D. Oppe, general manager of the Marconi Wireless Telegraph Company of Canada, who is also a director of the American company, has been in New York recently. When asked about the operations of his company at Glace Bay, Mr. Oppe said: "While we are not yet in active commercial operation between Poldhu and Glace Bay, we frequently exchange signals and are in constant communication with the American station at South Wellfleet, a distance of over 800 miles of land and water. Mr. Marconi has been devoting his time to perfecting communication between Poldhu and Gibraltar, a matter of great importance to the British Admiralty, and has not been able to devote his attention to the American station as intended. A large demand upon his time arises from his contract to install the long-distance station at Pisa to communicate with the Argentine, 6,200 miles. Notwithstanding these two important projects he is expected to return to America soon, and I confidently expect that regular communication across the Atlantic will be established soon. The Canadian Government, it is understood, has in contemplation the establishment of a number of stations in the Gulf of St. Lawrence for the purpose of aiding navigation, including one at Sable Island, which is situated 100 miles from the main coast of Nova Scotia in the direct line of vessels sailing from St. John and Boston, and within easy communication of the route traversed by New York and Liverpool vessels. A station will also be erected in Nova Scotia to connect with that at Sable Island, and one may be established at Cape Race."

Mr. Oppe said that the reason another station might be needed on the Nova Scotia mainland was that the Sable Island station would be tuned differently to the one on Glace Bay, thus avoiding interference with one by the other.

Electric Power at the Charlestown Navy Yard.

A large plant to supply power to the various buildings and shops in the Charlestown Navy Yard at Boston is being installed. It will cost about $300,000 when completed. The equipment will include a 750-kw Westinghouse-Parsons steam turbine, direct-connected to an alternating-current generator. It is intended to add three more machines of the same size later on. Two 100-kw motor generators, for transforming the alternating to direct current are now being built and others will be installed. From this plant, besides the power for operating the machinery in the large shops, power is to be supplied for running machinery along the water front and also on board any ships that may tie up at the piers. The power for the ships will be conveyed through heavy flexible cables.

Work has been begun on the pump well for the new dry dock, which is to be made of glazed brick, and will be 43 ft. in diameter and 55 ft. deep. The two great pipes, shaped like Ys, and each weighing 26,000 pounds, which are to go on the bottom of the well, have been successfully cast and will be laid at once. The pump, which will have a capacity for discharging 65,000 gallons of water per minute, will be electrically driven. The motor which will run it will be of 500 hp and will be directly connected on the same shaft. The pump will be able to remove all of the water, about 14,000,000 gallons, from the basin in four hours, and will also be connected so as to empty the old dock.

Traction in Massachusetts.

The annual report of the Massachusetts Railroad Commissioners for 1903 shows that during the twelve-month periods covered the operations of both the steam and electric roads were the largest on record. A notable feature of the report is that the number of passengers carried by the steam roads is, for the first time in ten years, larger than the number carried in 1893, when the electric roads began active competition. The increase in the number of passengers carried by the steam roads during 1903 compares with that of the electric roads as follows:

PASSENGERS CARRIED

	Steam roads.	Electric roads.
1903	123,162,793	504,662,243
1902	115,645,897	465,472,382
Increase	7,516,896	39,189,861
Per cent increase	6.5	8.4

The number of passengers carried by the steam roads in 1903 compares with 119,779,947 carried in 1893, the previous high record, showing an increase of 3,382,846, or less than 2 per cent. The increase in the number carried by the electric roads in the same period was 294,110,234, or 136 per cent. The increase in passenger earnings during 1903 compares as follows:

PASSENGER EARNINGS.

	Steam roads.	Electric roads.
1903	$42,524,082	$27,027,651
1902	41,440,170	24,918,865
Increase	1,083,912	2,108,967
Per cent increase	2.6	8.4

The percentage of total net earnings to gross liabilities (capital stock, and funded and floating debt) compares as follows:

	Steam roads.	Electric roads.
Gross liabilities	$394,277,139	$133,121,411
Total net earnings	37,866,139	9,508,284
Per cent net to liabilities	9.5	7.1

A comparison of surplus available for dividends and capital stock compares as follows:

	Steam roads.	Electric roads.
Capital stock	$235,834,466	$68,404,480
Surplus after charges	13,748,969	3,602,916
Per cent surplus to stock	5.8	5.3

Trolley for Calais, France.

The quaint old French town of Calais is to have trolleys. U. S. Consul Milner writes: "Calais still has horse tramways, operated by an English company that has a franchise to run for seventeen years. The municipality projected an electric tramway system and was granted the concession by the French Government. The contemplated system is estimated to cost $600,000, in which three lines were comprised, having a length of 16 miles—8 miles within the corporate limits of the city—the contemplated system of traction being the Dickinson trolley. It was intended to commence the construction next spring and have the same in operation within one year. These plans have been upset by the death of the contractor, whose heirs are now trying to sell his rights. This leaves an opening for some company to become his successor by arranging with his heirs. An opportunity may exist here for some enterprising American company."

Annual Meeting of the Northwestern Electrical Association.

(*By Special Telegram.*)

The twelfth annual meeting of the Northwestern Electrical Association was called to order in the club room of the Pfister Hotel, Milwaukee, Wis., Wednesday, January 20, with the president, F. W. Bowen, in the chair. A satisfactory report from the secretary and treasurer, Mr. Mercein, was read and adopted. The president's address was devoted to the subject of making the programme of the association at its meetings of the greatest value to the members, and it also considered several phases of central station business in relation to the public and the prosperity of the operating companies. It was heard with much attention and interest. The meeting adjourned until 1.45 P.M.

The Nomination Committee appointed by the chair consisted of R. N. Kimball, of Kenosha, Wis.; H. W. Frund, of Vincennes, Ind., and P. H. Korst, of Janesville, Wis.

The Membership Committee was constituted as follows: J. H. Harding, of Laporte, Ind.; W. H. Schott, Chicago, Ill.; Irving P. Lord, Waupaca, Wis.

The Committee on Uniformity of Advertising Matter reported and was continued, Mr. Harrow Almert being added.

The report of the Legislative Committee, although one which should be of much interest and importance, was not received.

The first paper read was that on "Central Station Heating," by W. H. Schott. It evoked a very spirited discussion regarding the operating features of heating plants in connection with central station work. The next paper read was an interesting one on "Coil Winding for Electrical Purposes," by Messrs. Richard Varley and Charles R. Underhill, the latter of whom presented it. There was no discussion. This paper treated on the rather undeveloped subject of the accurate design of electromagnets for general use and showed that the best method of obtaining data regarding the general behavior of electromagnets is to construct actual magnets, solenoids, etc., and obtain the data by making actual tests. As the magnetizing force necessary to operate any magnet is proportional to the ampere-turns in the winding, the ampere-turns once having been found, it is comparatively easy to design any winding for different voltages. If the current is to be left continually on the winding, the winding will heat considerably; therefore, in order to design a winding which will give the best result with minimum heating, it is also necessary to make actual tests from the various magnets to determine just how much heat they will radiate under various conditions. The economy of the winding was also referred to, and the relation between the actual winding space occupied by copper and by the insulation compared. Some formulæ were also given from which tables of constants have been made whereby the windings may quickly and easily be calculated. Stress was laid on the importance of detail, which shows that it is necessary to have accurate data in order to make the practical results check with the theoretical.

The next paper presented was that of Mr. W. Scheidel, on "Rectifiers." This was read by the secretary, and there was no discussion on the subject. An interesting paper was presented by Mr. John C. Keech on incandescent lamps in general, and their smashing point in particular. The address pointed out the universal adoption of the idea that 80 per cent. of the initial candle-power was the point at which the limit was reached of the useful life of a lamp. The lamp should be smashed when the cost of maintenance was greater than the actual profit from keeping the same up. Users, however, do not carry out the idea, which results in the company furnishing the current being condemned. There was no question of the fact that periodical renewals at the right moment were profitable, and he described improvements in make which aimed at and resulted in lamps burning out automatically at the smashing point. There was a lengthy discussion regarding the proper use of the lamps, in which many useful and interesting points were brought out by hard-headed practical members. The convention then adjourned until 10 o'clock on Thursday morning.

In the evening there was a theatre party given, to see the "Fortune Teller," at the Alhambra Theatre. On Thursday morning the session was arranged to begin with Mr. J. H. Waring's paper on "Storage Batteries for Central Station Work." The other papers will be carried out as per programme, already printed.

Mr. W. Sheidel, of Chicago, read a paper entitled, "The Electrolytic Rectifier and Interrupter," in which he described the Churcher alternating-current rectifier. It is stated that this device rectifies both waves of alternating current and consists merely of one jar, one solution and one set of electrodes. A transformer is required with a secondary of twice the direct-current voltage required plus the resistance loss; the secondary coil is tapped in the center, this tap remaining always positive. The rectifying cell is of the aluminum type and the active electrodes are attached to the secondary terminals of the transformer, the number depending upon the phase of the alternating current supplied. Between the active electrodes, but insulated from them, is placed an inactive electrode, preferably of platinum. Connected between this electrode and the center tap of the transformer is the battery to be charged, the direct-current motor or other apparatus to be operated.

In operation the current passes from the center tap of the transformer to the motor, from the motor to the inactive electrode in the rectifying solution; thence through the solution to one or the other active electrode, depending on which at that instant is negative to the center of the transformer. Inside the rectifier the current passes from the inactive electrode first to one then to the other active electrode, as the alternations of the cycle take place, the center of the transformer remaining positive at all times. It will thus be seen that one side of the transformer is active while the other is inactive during one alternation, and vice versa. The regulation of the direct current is best attained by placing an adjustable inductance between the transformer terminals and the active electrodes of the rectifier. The limit of the voltage of one cell of the Churcher rectifier is stated to be about 70 volts direct current. Through the use of two cells and two secondaries in one transformer, twice the voltage can be obtained, and by increasing the number of cells and the secondaries still further, higher voltages may be obtained.

The paper also refers to the interrupter invented by Mr. Churcher, which will work with any potential or frequency of alternating current and deliver a rapidly and completely interrupted direct current through the primary of an induction coil. The construction and method of operation is similar to the Churcher rectifier, the only difference being in the area of exposed contact of the positive electrode, which is so restricted that instantaneous interruption of current is obtained by the well-known Wehnelt effect.

In spite of the inclement weather experienced in the West, the attendance was good, and the association is to be congratulated, as before, on the practical character of its work.

Further Gift for the Union Engineering Building.

The committee of fifteen, representing the four national engineering societies and the Engineers' Club, on the gift by Mr. Carnegie of $1,000,000, have been doing a great deal of hard work, and this week it became known that notable progress could be reported by them. The plans prepared for the Union Engineering Building and for an entirely separate club house have brought out the fact that, with their large growing memberships this munificent sum would hardly cover all the wants of the various bodies, especially if the Civil Engineers should finally decide to come into the scheme. On Monday last this was brought to Mr. Carnegie's attention, when, with characteristic generosity and promptitude, he added immediately in writing to his previous famous letter, the statement that to make adequate provision for the Civils he would add another $500,000. He also provided at the same time for further purchases of property for the site.

The American Society of Civil Engineers held its annual meeting in New York City this week at the Carnegie Lyceum and then voted to send out a circular of pros and cons on the project and to take a letter ballot returnable in March as to whether the Civils should or should not join the sister societies. There was a great deal of animated argument at the meeting on the subject, some of the older members having apparently very strong views against accepting the gift or against joining hands with the other bodies. The action of the Civils in regard to the acceptance by them of the gift will be watched with great interest.

Bell Telephone Laundries.

An unusual state of affairs exists at Mansfield, Ohio. Spurred by the action of the laundry proprietors, plumbers and the gas fitters, who have pledged their support to the independent local telephone company, the Bell Telephone Company has rented stores and will engage in these businesses.

CURRENT NEWS AND NOTES.

GERMAN LAMPS.—A firm located at Cologne has just received an order from the City Council at Edinburgh, Scotland, for 10,000 incandescent lamps. It is reported that 34 firms submitted bids upon this order.

THE INDIANAPOLIS ENGINEERING SOCIETY has been organized at Indianapolis, Ind., to include in its membership civil, mechanical and electrical engineers and architects. The society starts with fifty members. Charles C. Brown is president and W. E. Buehler, secretary.

DEATH OF DR. HEFNER-ALTENECK.—Dr. Friedrich von Hefner-Alteneck, the distinguished German electrical engineer, died of apoplexy on January 7, at the age of 58 years. In 1872 he invented the drum armature for dynamos. He also invented one of the first differential arc lamps; a transmission dynamometer, and, in 1883, the "Hefner" amyl-acetate standard of light.

AN "OLD VINTAGE."—Mr. W. L. Frazee, superintendent of the government electric light plant and the police and fire alarm telegraphs at Honolulu, Hawaii, in a recent letter to this country says: "This plant is about the same as when first installed—no improvements whatever since 1886—using the same old transformers made by the Thomson-Houston Company. It has always been my desire to remodel it with the latest improved apparatus. I think it would make an interesting exhibit at the St. Louis Fair."

MAGNET STEEL.—In a paper read by Mr. N. Lilienberg before the Philadelphia Foundrymen's Association it is stated that it is possible to produce by superheated side-blown process steel uniformly lower in carbon and manganese than by any open-hearth or bottom-blown process. Many tests have shown by this process it is possible to increase the magnetic qualities of steel by 10 per cent. M. Tropenas has stated, and the claims have been corroborated by others, that the permeability and hysteresis curves of such steel approach those of Swedish iron.

SECRETARYSHIP OF AMERICAN ELECTROCHEMICAL SOCIETY.—As recently reported in these columns, Mr. C. J. Reed has announced that owing to pressure of professional work he cannot accept re-election to the office of secretary of the American Electrochemical Society. Among the names brought forward as candidates for the position are Dr. J. S. Richards, now president of the society; Dr. S. S. Sadtler and Dr. E. F. Roeber. Owing to the growing work of the secretaryship it is probable that a salary will be attached to the position hereafter.

TROLLEY IN SWEDEN.—Mr. E. L. Adams, United States Consul-General at Stockholm, Sweden, writes: "Stockholm's electric tramways now in construction are to be ready for use early next year. The tenders accepted for the new lines were made by Swedish and German contractors in combination. The American bidders were unsuccessful in securing the contracts. The amount to be expended in this work is about 3,000,000 kroner ($795,000). Several other cities in Sweden—Gefle, Malmo, Norrköping, Sundsvall and others—are contemplating exchanging their street railway lines from horse power to electric power."

ICE DAMAGES A NIAGARA POWER HOUSE.—A mass of ice in the form of a huge icicle which collected on the side of the bluff overhanging the power house of the Niagara Falls Hydraulic Power & Manufacturing Company, at Niagara Falls, became detached from its support and crashed through the roof of the power house, on Tuesday of this week. Press dispatches state that two roof girders were broken and a hole 60 ft. wide made in the roof. The ice and debris fell upon the machinery in the generating room, temporarily disabling some of the machines. The station was shut down for a short time to avoid short-circuits from the ice and water, but afterwards resumed operations.

A. I. E. E. JANUARY MEETING.—The January meeting of the American Institute of Electrical Engineers will be held at the Chemists' Club, 108 West Fifty-fifth Street, New York, on Friday evening, January 29, at 8.15 P.M. The following papers will be presented at this meeting: "The Alternating-Current Railway Motor," by Charles Proteus Steinmetz; "Speed-Torque Characteristics of the Single-Phase Repulsion Motor," by Walter I. Slichter. These two papers relate to the latest and most interesting advance in electrical engineering as applied to traction purposes. Mr. Steinmetz's paper deals with the subject from a simple mathematical point of view, and Mr. Slichter's paper from a more general point of view. It is expected that these two papers will provoke an exceptionally interesting discussion.

ELECTRICITY AT EXPOSITIONS.—Prof. W. E. Goldsborough, chief of the Department of Electricity, World's Fair, St. Louis, Mo., will lecture on "The Influence of Electricity upon Expositions" before the New York Electrical Society on January 27, at 19 West Forty-fourth Street. He will discuss the use of electricity in connection with exposition work since the introduction of electric power, starting with the very earliest and most primitive applications. The evolution which has taken place in the making of exhibit installations will be brought out, leading up, as it will, to an estimate of the installations which will be made in the Electricity Building at St. Louis. A general view of the electric decorative effects in connection with the interior and exterior illumination of exposition buildings will also be given. The lecture will be profusely illustrated by lantern slides. Ladies are specially invited, and aside from the general popular interest of the subject should enjoy the beautiful pictures presented.

SIGNALS UNDER WATER.—A special telegram from Boston of January 24 says: "Tests of the Gray system of submarine signalling were made to-day on board the steamship *James S. Whitney* during her trip from New York to this port. Submarine communication by bell signal was established with three lightships while the steamer was some distance from them, apparently showing that the system may be useful in averting collisions. On board the *Whitney* were representatives of the Canadian Government, who made the trip to test the efficiency of the system. By permission of the United States Government, four lightships on the course had been equipped with submarine bells, which were to be tolled automatically. The *Whitney* left New York at midnight last night, and at 2 o'clock this afternoon as the ship approached the Pollock Rip Lightship the distinct sound of a tolling bell was heard in the receiver in the pilot house. A few minutes later another bell was heard which, the officers said, was submerged at the Pollock Rip Shoals Lightship. At 7.20 o'clock to-night, as the *Whitney* neared Boston Harbor, the sound of a bell was heard clearly in the receiver, and the captain altered his course at intervals so that the sound of the bell was heard both from the port and starboard sides."

TURBINE ELECTRIC GENERATOR.—Some weeks ago we noticed a patent issued to Messrs. E. H. Porter and Burleigh Currier on a novel steam turbine generating set, and last week another patent was issued to the same inventors on another type of combined steam turbine and generator. On the peripheries of the turbine blades are carried toothed inductors similar to those used in the well-known types of inductor alternators. These, when driven by the turbine blades, act in multiple to vary the inductance between two stationary windings, one separately excited and acting inductively on the other, the generating winding. Bar windings are threaded through porcelain tubes laid through the magnetic circuit of laminated plate construction. In this machine the energy is thus transmitted direct from the turbine blades electrically. The ordinary iron and copper losses are increased above what is usually considered good practice in dynamo design so as to have the turbine blades heated to a temperature slightly in excess of that of the steam to prevent condensation on the blades, this superheating process thus enabling the heat of the so-called generator losses to be absorbed by the steam in its passage through the turbine. The generator shown in this patent differs from the previous one in being a combined turbine and a synchronous, separately-excited type of alternator, the first-mentioned having the turbine combined with the synchronous induction generator best adapted to operate in multiple with other generators of the synchronous type. The shaft of the turbine does not extend out of the case, the transmission being entirely electrical and the ends of the bearings are closed to prevent the escape of steam.

WIRELESS TELEGRAPHY IN PORTO RICO.—The wireless telegraph stations at San Juan and Culebra, Porto Rico, have, according to a dispatch from San Juan, been opened, and are working satisfactorily.

TO THE FRONT.—It is stated that the Japanese Government has ordered back to Japan twelve of the fifteen Japanese engineers who are at the Westinghouse Electric Company's plant at East Pittsburg, on account of the threatened war.

LIGHT FOR VENICE.—Mr. R. W. Bliss, United States Consul at Vienna, reports that for two years past a company has been steadily working to harness the water power of the River Celina electrically and promises to turn on current by January next. He thinks this will make an opening for many electrical appliances of American type and origin.

NATIONAL ELECTRIC LIGHT ASSOCIATION.—Secretary Davis, of the National Electric Light Association, visited New York last week to look after association affairs. He reports that the association is in a very flourishing condition. The programme for the 27th convention is being rapidly formulated, and will contain many novel features. The Question Box, in the able hands of Mr. H. T. Hartman, is already pretty well filled up with queries, but there is room for as many more as members wish to ask, and it is hoped that they will avail themselves freely of this means of gaining useful information.

ELECTRICITY AT TRIESTE.—Mr. F. W. Hossfeld, United States Consul at Trieste, reports a large plan on foot for the extension of the dockage and warehouse facilities at Trieste, all the cranes, hoists, capstans and other machinery of which will be driven by electrical power. He also states that the commission which the Austrian Minister of Railways sent recently to Milan to investigate and report on the electric railways of Lombardy, has recommended the adoption of electric traction for the new lines of railway of which Trieste will be the terminus. In the event of carrying out this recommendation, the new railways will be supplied with electric currents from the same power plant as the harbor.

TELEPHONY IN CALIFORNIA.—The city of Bakersfield, in proportion to its population, has, according to the report of the manager of the Sunset Telephone Company, more telephones in use than in any other city in California. It has 1,550 telephones in operation, and, based on the census of 1900, this means something over 36 to every 100 inhabitants. On the same basis Santa Cruz has less than 13 to the hundred, San Diego 12, Oakland 11, Los Angeles 12, San Francisco 12, Sacramento 11, Redlands 12, Napa 10, Hanford 28, Chico 23, Visalia 21, Fresno 21, Eureka 20, Pasadena 20, Salinas 17. All of these proportions are high. The Bakersfield ratio would give about 25,000,000 telephones for the United States, instead of the present 5,000,000.

NEW TUBE FOR LONDON.—A cable dispatch of January 16 says: "Another twopenny tube is to be thrown open to the public on February 1. This is the Great Northern & City Railway, between Finsbury Park and Moorgate Street, which is so near completion that a party has been taken over the whole route in a model train for a tour of inspection. The road is nearly four miles long and brings a very populous district in touch with the city. This tube is a distinct advance on the similar railways already working in London. Some of those who made the trip pronounced it the best underground railway so far constructed in the world. The tunnels have a 16-ft. diameter, as compared with the 11 ft. 8 in. of the Central London Railway, and this permits the use of larger rolling stock. The cars are somewhat longer than those in use on other tubes. They are built of teak, with a height of over 12 ft., which makes them roomy and airy. They are, in fact, of equal width with the widest carriage that can be run on any British railway, the bulging sides making for greater comfort. All the seats are crosswise, with a center aisle. There are doors in the center of the cars for emptying and filling with great celerity at the terminals. The stations along the route are roomy, with big lifts and wide staircases. All the structures underground, including even the signalmen's cabins, are fire-proof. The trains are made up of seven coaches, three of which are motor carriages. One of these is placed in the middle of the train. 'An all-British twopenny tube!' cries the *St. James Gazette*, describing the railway. The Brush Electrical Engineering Company built many of the carriages at its English works. They are supplied with Westinghouse air brakes and the motors were built by the General Electric Company, while the driving system is the Sprague multiple unit."

LETTERS TO THE EDITORS.

Resistances in Transformer Circuits.

To the Editors of Electrical World and Engineer:

SIRS:—On August 8, 1903, you published my article on "The Effect of Series Resistance in the Transformer Circuit." I learned just a few days ago that the *Elektrotechnische Zeitschrift* brought out in its issue of September 10, 1903, page 753, an abstract of that article, pointing it out as an interesting one. Later, in their issue of October 8, 1903, page 854, Mr. Gustav Benischke discussed the article fully under the heading "Letters to the Editor," and his conclusion is that my statements are wrong. Furthermore, in their issue of November 12, page 949, Mr. Hugo Grob wrote that Mr. Benischke made a ridiculous failure in the objections brought up against my paper, because its exactness is evident not only by the theory, but by the results of the experiments given in the paper.

I would beg to suggest the propriety of the *Electrotechnische Zeitschrift* communicating with ELECTRICAL WORLD AND ENGINEER under such circumstances, so that the author may either explain or defend his standpoint under such circumstances.

PITTSFIELD, MASS. HENRY PIKLER.

[It is not customary for editors to adopt the practice suggested by Mr. Pikler.—EDS.]

Reduction of Fire Losses by Proper Inspection.

To the Editors of Electrical World and Engineer:

SIRS:—The recent disaster at the Iroquois Theatre in Chicago carries grave lessons home to every thoughtful resident of our large cities. It is appalling to realize that the latest and most scientific methods of construction do not of themselves always insure safety, and this horrible catastrophe is a tragic commentary on the imperfections of human knowledge. We are too inclined in these days of wonderful material progress to take it for granted that the great forces of nature are so well tamed that they need little watching when applied to the service of man.

Of all the natural elements, fire is perhaps the best friend and the bitterest enemy of the human race. The annual losses in life and property from this source reach a tremendous total. Gradually the world is awakening to the importance of devoting its best thought to fire protection and prevention, and in the last few years a new profession has come to the front with this in view—Fire Insurance Engineering.

Whatever the final cause of the Chicago calamity may have been, the one tremendous lesson of the hour is the vital importance of expert inspection in every building where heat, light and electricity are utilized. The careless handling of such forces by dishonest contractors and ignorant, underpaid employees is simply a free invitation to a tragedy—it is insanity flying in the face of Providence.

Accidents like the breaking of a steel rail or a steamship shaft are at times unavoidable, and cannot always be foreseen. They are a part of the price which we pay to nature for making use of her exhaustless power and wealth. Little, if any, excuse exists, however, for fire in a modern building properly constructed and inspected. The fire underwriter should know this if the public does not, and upon him rests an immediate responsibility—he must bend every effort to secure expert inspection of each structure which he insures, and not one cent of insurance should be placed until the building is pronounced safe by an experienced fire insurance engineer. Let the underwriter take this decided stand, insisting on safe construction throughout, and the public will soon demand the same thing on its own account. Nor should the precautions end here. Frequent inspection should be made of every building where forces capable of causing fires are in operation, especially in buildings where large numbers of people congregate. Thus, no scenic application of electricity should ever be permitted in a theatre until the arrangement of the apparatus and wiring satisfies the fire insurance engineers' most rigid requirements of safety.

Already two laboratories for the study of fire prevention are in operation in this country. One of these is connected with the Massachusetts Institute of Technology, in Boston, and the other is located in Chicago, both being supported by powerful insurance interests. In order to provide the systematic inspection required, however, many trained men are needed. This will cost a large amount of money each year, but the reduction in fire losses ought to more than offset the expense. Surely, the saving of many human lives each year is a sufficient object in itself.

It is time for the philanthropist and the underwriter to invest capital in proper inspection. It is time for the technical school and college to add to its curriculum a course in fire insurance engineering. It is time that some of the young men who are facing the overcrowded condition of the older professions should make fire prevention their life work, and it is time that the great public realized the importance of systematic and scientific efforts to rid the world of fire losses.

DENVER, COLO. HOWARD S. KNOWLTON.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Commutation.—PICHELMAYER.—An illustrated paper read before the Electrical Society of Vienna. He discusses the electric causes of sparking at the commutator. If an ordinary direct-current dynamo, the brushes of which may spark somewhat, is run at a gradually decreasing speed, while the current output and the excitation remain constant, it is found that the sparking becomes less and less and disappears entirely at very low speed. In this case, if we consider the local circuit in which commutation takes place and which contains the brush, the two commutator segments touched by the brush, their connections with the armature, and the short-circuited armature coil, then the only e.m.f.'s to be taken into account at very low speed in this circuit are those consumed by ohmic resistance, while at higher speeds two other kinds of e.m.f.'s come into play, namely, the e.m.f. of self-induction and the e.m.f. induced from the external field, which is generally small at this point. As long as the speed is low and only the volts lost by ohmic resistance are to be considered, the current distribution may be easily found by Kirchhoff's rules. The author shows that in this case, if the current flowing in the short-circuited coil is plotted in a diagram as a function of the time, it is represented by a nearly straight line, as long as carbon brushes are used and the transition resistance from the brush to the commutator is at least twice as great as the ohmic resistance of the short-circuited coil and its connections with the commutator segments. The greater the transition resistance, the more will the time curve of the current of the short-circuited coil approach a straight line. He calls the condition under which the curve is a straight line, the "pure resistance commutation," and considers this condition as the ideal case, since the current density at any point of the brush is then constant during the whole period of commutation, so that no sparks can occur, the produced heat being a minimum. The problem is now to produce the same condition at higher speeds. Since here the e.m.f. of self-induction and the e.m.f. induced from the external field are to be taken into account, the problem is to arrange matters so that the latter two e.m.f's are exactly equal and opposite. The result will then be that we have again the condition of pure resistance commutation. If the curve mentioned before representing the current in the short-circuit coil as function of the time is a straight line, then the e.m.f. of self-induction will be constant during the whole period of commutation and the problem is to make the e.m.f. induced from the external field also constant and exactly equal to the e.m.f. of self-induction. The well-known means by which sparking has been counteracted for many years is to advance the brushes from the neutral zone; in the light of the author's theory, the object is to bring the short-circuit commutating coil into a somewhat stronger field, so that the e.m.f. induced from this external field will counterbalance the e.m.f. of self-induction. The author points out that all designers have arranged to have the field at the point where they place the brush nearly constant or at least increasing only slightly. For special machines which run at very high speed, like those coupled to steam turbines, this remedy is, of course, not sufficient, and it is then necessary to provide a special "commutating field" at the place where the commutation takes place, and of such a size that the e.m.f. induced by it in the short-circuited coil exactly counterbalances the e.m.f. of self-induction induced in the same. This may be done by means of special commutation poles, as shown in Fig. 1 for a bipolar machine. They are supplied with the armature current, and by a suitable design it is easy to insure that the commutation field is constant over the whole commutation zone. For calculating the e.m.f. of self-induction the author recommends the

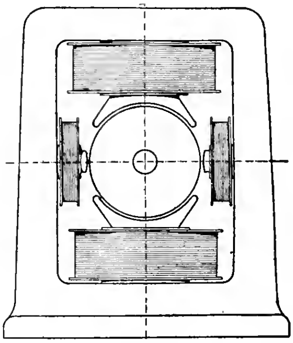

FIG. 1.

formula of Parshall and Hobart, and one of the main results of his paper is that the so-called reactance voltage (which, according to older theories, should be below a certain limit) may assume any value whatever as long as a commutating field of such a size is provided that it counterbalances the reactance voltage. In the discussion which followed, Deri remarked that the theory of the author exactly corresponds with what he has done for years in his direct-current dynamos in which he annuls the armature reaction and also provides a commutating field for counteracting the reactance voltage in the short-circuited coil. He states that many machines of his system are in practical use, and that direct-current dynamos driven by steam turbines, and running at 4,000 r.p.m., with a capacity of 1,500 kw, have proven practically successful. He also mentioned experiments in which he found that by means of the improved commutation device, it is possible to produce in shunt machines with ordinary commutator much higher voltages than heretofore. On account of the annulment of all obnoxious and dangerous e.m.f's produced during commutation, it is possible to increase the voltage between commutator segments far beyond those values which were heretofore considered as a limit. Orgler gave some details of the successful operation of compensated Deri machines in connection with the Orgler system of hoisting. Pichelmayer replied that he did not want to minimize the merit of Deri, but it is important to know that the accomplishment of Deri can also be obtained in other ways if only the general principles explained in his theory are followed. Reference was also made to a device of Seidener, who uses an auxiliary armature, running between the main armature and the commutator within the poles of a special magnetic field. The connections between main armature and commutator form the windings of the auxiliary armature. Seidener stated that Edison had patented a similar arrangement in 1887.—*Zeit. f. Elek.* (Vienna), January 3. A shorter account of the principles given in

Pichelmayer's paper is given in an article in *Elek. Zeit.*, December 31.

Determining the Lengths of the Poles of Field Magnets.—COOKE.—A communication in which he gives a formula for determining the lengths of the poles of field magnets by a more direct method than is at present adopted. Since the length of the pole depends entirely on the length of the bobbin to be put on it, the method now used is to assume a trial value, then make a drawing of the machine, and from this calculate the mean magnetic paths, from which are deduced the total number of ampere-turns required per pole. Assuming a suitable magnetizing current, it is now possible to find the number of turns and hence to design the bobbin. This gives a new and final value for the pole length which necessitates a new drawing, and alters the mean magnetic path in the pole cores and yoke. The schedule has now to be altered and the current changed to suit the new number of ampere-turns. The formula given by the author states that the length of one layer of wire equals a numerical constant multiplied by the product of magnetizing current and number of turns of wire per bobbin, divided by the product of depth of wire on the bobbin and current density in the wire. The numerical value varies between 2 and 1.5, being 2 for a magnetizing current of 1 amp. and 1.5 for a current of 10 amp. for a current density of 700 amp. per sq. in. The method of using this formula is as follows: Make a drawing of the armature as before, and from it calculate the number of ampere-turns required for the gap, teeth and armature body. This gives the product of magnetizing current and number of turns of wire per bobbin, required for the formula. The depth to which the wire may be wound is governed by the permissible heating, and depends, therefore, on the specifications. The length of the bobbin can thus be found; to this must be added the thickness of the two bobbin ends and the insulation between the wire and the bobbin to obtain the true length of the pole. The field magnets are then added to the drawing of the armature.—Lond. *Elec.*, January 1.

REFERENCE.

Repulsion Motor.—BLONDEL.—Continuations of his long illustrated serial on single-phase commutator motors. In the present installments he deals with the theory of the repulsion motor. In view of the highly mathematical character of the paper, an abstract is impracticable.—*L'Eclairage Elec.*, December 12, 19.

LIGHTS AND LIGHTING.

Efficiency and Temperature of Nernst Lamp.—INGERSOLL.—An account of a determination of the efficiency of the Nernst lamp by the method of Angström, in which the total spectrum of the light is dispersed in order to screen off all but the visible spectrum and the visible rays are then recombined into white light by means of a cylindrical lens and balanced photometrically against the total radiation from another exactly similar source. The energy of the two radiations can then be compared by replacing the photometer screen with a bolometer or thermopile. The filaments were burned freely in the air, without heaters, on a 100-volt alternating-current circuit. He found that Nernst filaments are by no means uniform, since new filaments show an efficiency of from 4.35 to 4.70 per cent., while the efficiency falls rapidly for about the first 20 hours, decreasing to a mean of 4.3 per cent. and varying only slowly after this. Tests of filaments of 40 hours and upwards give a mean efficiency of 4.17 per cent. Some very old glowers gave only 3.6 per cent. After a glower has been burned upwards of 20 hours it obtains a marked crystalline appearance, and it is probable that a fall in efficiency is due to a greater radiating surface and consequent lower temperature afforded by the crystalline structure. If, as is now proposed by the Westinghouse Company, the glowers are aged before they are sent out, the deterioration with time may no longer be observable. The energy curve plotted from Wien's law, which gives the efficiency 4.17 per cent., i. e., which gives the ratio of visible energy to total energy = 0.0417, is that corresponding to the temperature 2360° C. This, then, would be the temperature of the Nernst glower, considering it as a "black body" in the sense of thermodynamics. This value lies well within the limits 2200° and 2450° C., given by Lummer and Pringsheim.—*Phys. Rev.*, November.

Distribution of Light from Incandescent Lamps.—WILD.—An article in which the author gives a table comprising the results of measurements of the candle-power of eight lamps in all directions, with diagrams of the filaments of these eight lamps. This table shows that the candle-power measured normal to the mean plane of the filament (called by him the normal candle-power) can generally be accepted as a measure of the mean spherical candle-power of the lamp. In practice the light emitted in any direction is not strictly proportional to the apparent surface of filament presented to that direction; the cause of this discrepancy is that the glass bulb does not transmit all the light rays that fall upon its surface, but reflects back a portion. The surface being curved and the filament not being equidistant from all parts of the bulb, the reflected light is to a certain extent concentrated into particular directions. When the direction in which the best illumination is required is not specified, lamps should be tested for mean spherical candle-power. As, however, this measurement is somewhat tedious, many substitute for it the measurement of the mean horizontal candle-power of the lamps to be tested. The mean horizontal candle-power is, however, very far from being proportional to the mean spherical candle-power. A far better plan is to measure the normal candle-power (as defined above). Speaking generally it appears from the table that when the mean horizontal candle-power is high, the vertical candle-power is low and vice versa, but no distinct law can be traced. For the general illumination of a room, a lamp should be chosen giving high candle-powers horizontally and at 30° below the horizontal. When a lamp is required to illuminate a small area, such as an office table, a filament should be chosen giving as large light as possible vertically downwards and also at 60° below the horizontal.—Lond. *Elec. Rev.*, January 1.

POWER.

Development of Small Water Powers.—BELL.—An article on the development and utilization of water powers having a capacity of less than 500 hp. The author assumes a stream having a reliable flow of 100 cu. ft. per second during the dry months and a working head of 25 ft., the maximum flow being 400 cu. ft. The assumed average minimum flow would yield just about 225 hp if utilized with a first-class turbine, and the electrical product of this power—a little over 150 kw—could be sold twenty-four hours per day, save for a few days at a time in very dry years. For nine months of the year twice this output could be delivered. Since an electric light plant would be the best customer for this power, the author considers how far storage can be brought into play to build up an output big enough to be of some use. With a normal minimum flow of 6,000 cu. ft. per minute the working power for a 12-hour run can be developed by storing a little over 4,000,000 cu. ft. of water. This would mean drawing down a 100-acre pond one foot at night and letting it fill up when the load is substantially off during the day. In a very dry year there may be a further deficit of flow amounting to a little over 2,000,000 cu. ft. in every twenty-four hours, so that the storage pond can be planned for if feasible. The development of the power does not require a large outlay. A well-ballasted timber crib is recommended for the dam. A small penstock is recommended. The number of hydraulic units should be so chosen that the temporary crippling of one will not cause serious inconvenience. The total capacity should be put, say, in four 150-kw machines. Any more than this would probably lead to increased expense, and any less might cause too severe an overload in case one machine shut down. Regarding the electrical system to be employed, if the power was to be developed for lighting the system is not of much consequence, direct current answering this purpose; if the power is to be transmitted a moderate distance, and loose pulleys are used on all but the smallest motors, a straight single-phase system answers, but where the power is transmitted a long distance and the actual distribution is carried from a sub-station a 10,000-volt transmission line is recommended. All the requisites for a first-class transmission line are considered. A possible supplementary steam plant is discussed in connection with the sub-station.—*Am. Elec.*, December.

Italian Hydraulic Power Station.—A note on the water power station which has recently been completed at the foot of Mont Cenis for power transmission to Turin, forty miles distant. The head of water is no less than 2,830 ft. and the quantity of water is 35.3 cu. ft. per second; 11,500 hp are thus produced, and by regulating the flow of water by means of a dam, 16,000 hp may be obtained if necessary. In order to avoid excessive pressure in the pipes, the head is utilized in two stages and at present only the lowest stage is completed. Three generating sets, each consisting of a turbine directly coupled to a 1,400-kw alternator, are installed at present, one set acting as reserve. The head of water of this lowest stage is 1,380 ft. and the turbines rotate at a speed of 500 r.p.m. The alternators, which weigh 33 tons each, generate current at 3,000 volts with a full-load efficiency of 96.5 per cent. The exciting current is furnished by a 110-hp turbo-generator set. Water-cooled transformers raise the voltage to 30,000 volts for transmission to Turin.—Lond. *Elec.*, January 1.

Traction.

Alternating-Current Traction.—Bell.—An article in which the writer calls attention to the almost simultaneous production in three different countries of a single-phase railway motor along somewhat parallel lines, although they differ in details. He states the objection to polyphase induction motors and some of the difficulties heretofore encountered in constructing a single-phase motor. Referring to the Lamme or Westinghouse motor, he says that the performance of this new motor is quite comparable with that of standard direct-current motors, and although it is somewhat heavier does the same work and apparently does it well. At starting the power factor is low, but during a two-mile run it is approximately 87 per cent., and at full speed above 95 per cent. He then refers to the Eichberg-Winter motor, which belongs to somewhat the same class as the Lamme motor, but is not an ordinary series motor, being more akin to the Thomson repulsion type of alternating-current motor. The Finzi motor is also referred to.—*St. R'y Jour.*, December 19.

Interurban Road in Switzerland.—Somach.—A fully-illustrated description of the electric road between Wetzikon and Meilen, of 22.5 kw. length in the Zuricher Oberland. The trolley system is used, with the rails for the return, the voltage being 750. Each car is provided with four 22-hp, 375-volt motors, divided into two groups, each containing two motors in series. The power is supplied from the Beznau water power plant in the form of 25,000-volt, 50-period, three-phase current. Three 160-kw transformers reduce the voltage to 460, while two 140-kw rotary converters change the current to direct at 750 volts.—*Le Génie Civil*, December 26.

Electrification of British Railway.—An article on the electric equipment of the Lancashire & Yorkshire Railway, which decided about a year ago to electrify about 23 miles of double track. Operation will be started early this year. The trains will be composed of two first and two third-class cars, the third-class cars being equipped with four motors of 150 hp each. Direct current is supplied from a third rail at 600 volts. The power station contains five steam-driven generating sets, four of 1,500 kw and one of 750 kw, three-phase currents at 7,500 volts with a frequency of 25 periods being generated. Three-core paper-insulated metallic-sheathed cables laid "solid" convey the high-tension, three-phase currents to four sub-stations. The sub-station equipments, similar in character, consist in twelve air-cooled transformers and four 600-kw synchronous converters.—Lond. *Elec.*, January 1.

Traction Plant.—Fumero.—A fully-illustrated description of the Morbegno station, which supplies current to the Valtallina Railway in Northern Italy. Three-phase currents are generated at 20,000 volts and distributed to transformer stations along the line, in which the voltage is reduced to 3,000 volts, which is the pressure at which the current is supplied to the cars. The power station contains three turbine-driven, three-phase generators, each running at 150 r.p.m. and giving 1,500 volt-amp. at 20,000 volts, with a frequency of 15 and a power factor of 0.7. Each machine has 12 poles. The installation is described in detail with many illustrations.—*Elcktrische Bahnen*, December.

Reference.

Cleaning Third Rails in Open Country.—The third-rail system of the Grand Rapids, Grand Haven & Muskegon Railway Company has been kept free from ice and sleet through several storms this winter by the use of a solution of chloride of calcium poured on the rail through tubes extending from reservoirs carrying this solution, which are located in the motorman's vestibule, to a point directly over the third rail. The flow of the liquid can be regulated easily.—*St. R'y Jour.*, December 26.

Installations, Systems and Appliances.

British Central Station.—An illustrated description of the recently-opened electricity works of Christchurch. The power house contains two steam dynamos, each of 100-kw capacity, running at 450 r.p.m., and giving 500 to 550 volts either as compound or shunt-wound machines for supplying power both for lighting and traction. In connection with the lighting supply, two motor balancers are provided, each of 25-kw capacity. There is also a storage battery of 244 cells, giving 175 amp. for one hour. The pressure across the outers of the three-wire system is 500 volts. For public lighting 65 Nernst lamps of 84 cp and 44 of 42 cp have been installed. At present the equivalent of 1,500 lamps of 8 cp are connected to the mains.—Lond. *Elec. Rev.*, January .1.

Electro-Physics and Magnetism.

Eddy Currents.—Thornton.—The first part of an illustrated paper read before the Newcastle local section of the British Institution of Electrical Engineers. He first describes experiments made with massive cast-iron and steel rings, and then discusses tests of direct and alternating-current machines. From his results it can be concluded that if in any machine the field current shows a synchronous variation caused by armature reaction, of about 10 per cent., there will be a loss in the core by eddy currents, which will be a large fraction of the total losses in the machine. In alternating-current machines the chief source of the eddy current loss in the magnet frame is variation of armature reaction, while in direct-current machines there exist four possible sources of disturbance. The first and most important at light load is imperfect centering of the armature or adjustment of the air-gaps; the second is the variation of reluctance caused by the teeth of the armature moving across the pole face; the third is the slight peripheral shift of the cross magnetizing belt to and fro during commutation; and the fourth is the variation of reaction set up by a rise and fall of armature current, caused by phase swinging or uneven turning movement of the engine. He reproduces some curves taken by the oscillograph, showing the instantaneous distribution of polar magnetism in dynamo electric machines. It is shown that when the brushes of a generator under load are moved backward the magnetism in the gap is caused to oscillate at a speed much higher than that of the machine, and in ripples. These are in a state of oscillation, the amplitude of which is greater with strong fields and for brush positions, which correspond to commutation taking place in a strong field. The effect does not depend upon sparking at all.—Lond. *Elec.*, January 1.

Interruption of the Primary Circuit of Induction Coils.—Turpain and Blondel.—Abstracts of two papers read before the French Association for the Advancement of Science. It is on the rapidity of interrupting the primary circuit of an induction coil that the length of the sparks depends, obtained between the terminals of the secondary, other things being equal. If the interruptions follow each other rapidly enough, the condenser of the induction coil may be left out to advantage. Turpain has obtained similar results with the use of an ordinary interrupter, but constructed in such a way that the interruption takes place simultaneously at different points. Blondel describes a method he has devised of using the alternating current of a supply network without interrupters for operating an induction coil. His device is similar to that of Tesla, a transformer being used, the 110-volt primary of which is connected across the mains, while the 5,000 or 10,000-volt secondary is shunted by a condenser and is connected in series with a spark-gap and the primary of the induction coil to be operated. Every discharge of the condenser produces in the primary of the induction coil oscillations of sufficient rapidity.—*L'Eclairage Elec.*, December 12.

Electro-Chemistry and Batteries.

Electricity Direct from Carbon.—Lorenz and Reed.—Two papers on the problem of getting electricity direct from carbon. Lorenz gives a summary of the theoretical considerations to be taken into account in any attempt of solving this problem and discusses in detail the thermodynamical foundation of the theory of galvanic cells. While a carbon cell is theoretically possible, he believes that much work is still to be done before the problem is solved. Reed discusses in detail the two recent cells devised by Jone (Digest, December 5) and Reid (Electrical World and Engineer, December 12). He considers that the regeneration of the substances in Jone's cell would require an enormous amount of work, and that the mere removal of stannous oxide from the cell and its separation from the electrolyte would cost for labor alone more than the coal would cost for producing the same amount of power by steam. "If we were to ignore losses of material altogether and consider only all the losses of energy occurring in the cycle of processes proposed by Jone, the cost of power would appear to be not less than 50 to 100 pounds of coal for horse-power-hour. In his criticism of the Reid gas cell Reed discusses all the chemical reactions which can occur in this cell and shows that, if judged from the heat of reaction, the e.m.f. of this cell could not be accounted for electrochemically. "The e.m.f. which is claimed for this battery is, therefore, entirely an almost entirely thermoelectric."—*Electrochem. Ind.*, January.

REFERENCE.

Reviews of Electrochemical Industries.—Richards and Fitz Gerald.—Two articles giving summaries of the present status of electrochemical industries. Richards discusses the conditions of commercial electrolytic methods and deals especially with the alkali industry and with the refining of copper, lead and gold. Fitz Gerald gives a review of the electric furnace industries in 1903. Much progress has been made in furnace design, and it is probable that in future the electric furnace will be applied to processes requiring only a comparatively moderate temperature, but exact temperature regulation.—*Electrochem. Ind.*, January.

Units, Measurements and Instruments.

Integrating Alternating-Current Wattmeter.—An illustrated description of a new alternating-current integrating wattmeter of the induction motor type, devised by Ferranti. The aluminum rotable disc, *D*, mounted on the spindle, *S*, and geared to a train of wheels, *C T*, actuating the index hands, serves the double purpose of an armature receiving the driving torque of the meter coils and also the retarding torque of the permanent magnets, *P M*. One shunt coil, *Sh C*, placed round the coil, *C*, of a special tubular electromagnet, *T M*, constitutes the shunt system. The core of this magnet has

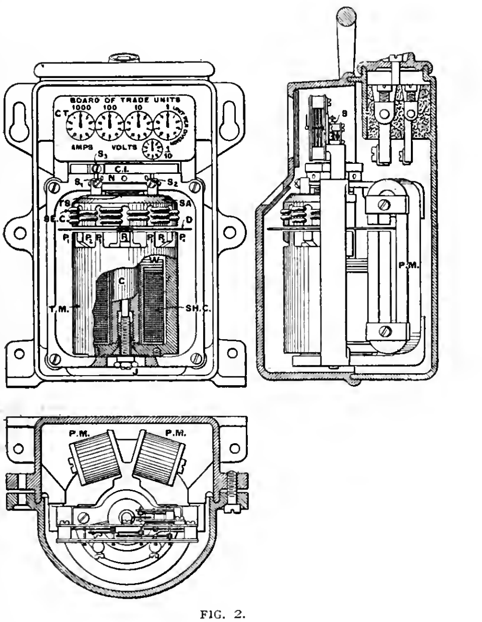

FIG. 2.

three outward radial poles, P^2, alternating with four inward radial poles, P^1, from the shell or tube of the shunt magnet, the plane of these poles being horizontal and parallel to the disc. Since the shunt circuit in the induction motor type of meter must be highly inductive, this special tubular magnet has been adopted, no chocking coils, secondary circuits, resistances or compensating coils being required. The series system consists of a slotted armature, *S A*, above the disc, the series coils, *Se C*, being wound in these slots. The slots of the series armature are almost directly above the poles of the tubular magnets. If the shunt circuit be inductive, the eddy currents produced in the disc by the shunt field will be in phase with the impressed e.m.f. These eddy currents are acted on by the series field, which is in phase with the load current, giving a driving torque on the disc proportional to the e.m.f. of the circuit multiplied by the amperes and by the cosine of the angle of lag of the main current behind the e.m.f., this being the true watts supplied to the circuit through the meter. The retarding torque due to the permanent magnets is proportional to the speed, and the disc, therefore, revolves with a speed which is proportional to the watts. For the purpose of compensating for any dissymmetry in the magnetic system, due to small irregularities in material, workmanship and pivot friction, it is necessary to have some adjustment. The series magnet is left slightly out of center in the direction which gives a slight torque on the shunt alone, and thus can be accurately adjusted to compensate for pivot friction or for any dissymmetry in the magnetic circuit met with in manufacture. The adjustment can be very accurately made by means of the two screws, S^1 and S^2. The constant of the meter is adjusted by lowering or raising the series armature by means of the nut, *N*, on the threaded spindle, *T S*, and after adjustment the series magnet is securely fixed by means of the storing clamp, C^1, and the screw, S^3. The following limits of accuracy are given: 1½ per cent. from 1/10 to full load, and 2½ per cent. from 1/20 to 1/10 load. A 10-amp. meter is said to start with 0.05 amp.—Lond. *Elec.*, January 1.

Localizing Faults in Hooper's India Rubber Core.—Ohlson.—In a cable factory the localization of a fault in an india rubber core often becomes necessary after it has been covered with yarn or metal tape. Occasionally this fault is of high resistance, and cannot be broken down for the purpose of a loop test, even when subjected to great electrical pressure while immersed in water. The author has used the following method with great success for three years: The length is slowly passed through a bath of water or wax at a temperature of about 200° F., and the leakage through the dielectric carefully noted by the deflection of a sensitive galvanometer, using as large a battery as possible. As soon as the fault enters the hot bath the deflection on the galvanometer scale will begin to rise owing to increased leakage through the fault. It will fall again as the fault passes out of the hot bath, so that the operation may be performed several times over at the suspected place to obtain an exact localization. Besides faults of low resistance, due to injury, the most minute imperfections are exactly located by this method, if it is carefully performed. Even in cases where the defect has only been apparent by a slight decrease in the rate of electrification when testing with 1,200 Lèchance cells, giving a galvanometer constant of over 2,000,000 megohms, and the dielectric resistance of even such short lengths as 1,000 or 2,000 yards has been very little altered by its presence, the above method has never failed to localize the defect within a few inches, without breaking the covering of the core.—Lond. *Elec. Rev.*, January 1.

REFERENCES.

Block Signals.—Hart.—An article on steam railroad practice in block signalling on double-track roads. The operation of the trains is not dependent upon the block signals, as they are used as an auxiliary only to train orders which are issued by the train despatcher. He thinks that many electric railway companies believe that with block signal systems train despatching, loses its importance, and he wishes to correct this impression.—*St. R'y Jour.*, December 19.

Wave Meter.—Doenitz.—An illustrated translation in full of the German article recently abstracted in the Digest on an instrument for measuring the wave length of wireless telegraphy waves.—Lond. *Elec.*, January 1.

Telegraphy, Telephony and Signals.

Douglas Exchange of the Chicago Telephone Company.—An illustrated description of this recently-completed exchange. The general features of the equipment follow standard Bell practice. In addition to the regular equipment, the cords in 33 positions are equipped with coin-collecting keys. The number of answering jacks varies from 60 to 160 per operator, depending upon the class of subscribers served. All positions in the office are equipped with breast plate transmitters which are connected to the switchboard through suitable plugs and cords. The incoming trunk board embodies a new system of incoming trunk lines, whereby it is possible to operate 40 trunk lines per position as compared with 25, which has been the usual practice. The most important feature of this circuit is the absence of any keys. A special relay is placed in the circuit of certain lines and this, in connection with the relays on the incoming trunk lines, automatically selects the proper generator for ringing a subscriber's bell. The trunks have the usual guard and supervisory signals. The subscribers' answering switchboard is arranged in the form of a horseshoe around three sides of the room. It is a standard relay, multiple, central-energy, lamp-signal board and consists of fourteen eight-panel, three-position section, with a present equipment of 3,500 lines.

The ultimate capacity of the board will be 9,600 lines, divided into 19 sections. The board does not differ in its general features from the others operated in the city by the company, except in the use of multiples on four-party lines, a separate multiple being provided for each one of the subscribers on such a line. The ten-party lines are multipled, but restricted to the ten-party line trunk board. The exchange is provided with three overflow positions to equalize the load during the busy hours. "Sick" lines are also provided; these are on the subscriber board and are known as the "hospital positions." The exchange is equipped with one hospital position and 200 auxiliary cords to be used during storm troubles. An information position is also equipped.—*Am. Elec.*, December.

Central Energy Intercommunicating Telephone System.—Webb.—An illustrated article in which the author shows how the principles employed in central energy telephone exchange systems have also been applied to intercommunicating systems. He describes an arrangement for use with an automatic switch, where centralized talking and ringing batteries and two-line wires for each telephone station are desired or considered necessary. The switch is of the push-button type and is very positive in action, this arrangement being convenient and fully as good, if not better, than a rotating switch, which, in the case under discussion, would have to be double in some way. The author describes a system suitable for a building requiring only three or four telephones and where communication between a central office and the sub-stations only is required. The system is merely intended as a simple substitute for a speaking tube system and is not supposed to meet the requirements of a regular telephone system.—*Am. Elec.*, December.

Miscellaneous.

Patents Expiring 1904.—A list of British patents of interest to electrical engineers which will expire during the present year. Among them are two dry cell patents of Hitchcock and Hellesen, a patent by Langhans for depositing a coating of silicon or boron on incandescent lamp filaments in order to lessen the effect of oxidation, two patents of Ferranti for electricity meters, two patents of Lemp for electric welding, a patent of Lord Kelvin for a mariner's compass, several patents by Weston, Ayrton and Mather for measuring instruments. The manufacture of switches and fuses will be facilitated, it is thought, by the expiry of the patent for the Mordey powder fuse and of the patent of Drake and Gorham relating to spring contacts for switches. A patent of Dobrowolsky and Mamroth for distribution of electricity by a four-wire, three-phase system and another patent by Dobrowolsky for the insertion of resistance in rotors of induction motors for regulating purposes will also expire.—Lond. *Elec.*, January 1.

Gilbert.—An illustrated reprint of part of the chapter on electrics from Gilbert's "De Magnete," with notes of S. P. Thompson and an account of the life and work of "Gilbert of Colchester, father of electrical science."—Lond. *Elec.*, December 11.

New Books.

Der Elektrische Lichtbogen. Bei Gleichstrom und Wechelstrom. By Berthold Monasch. Berlin: Julius Springer. 266 pages, 141 illustrations. Price, 9 marks.

This work—a text-book upon the arc lamp—covering a large amount of ground. There is a short introductory chapter on the history of the arc. Several chapters are devoted to the technics of the arc with direct currents and with alternating currents. Then follow chapters upon the various applications of arc lamps. The final chapters refer to arc lamp mechanisms, projectors, enclosed arc lamps and flaming arcs. A list of German patents on arc lamps and arc lamp applications since 1877 occupies an appendix. The book is clearly written and illustrated. It covers both the theoretical and practical sides of the subject remarkably well, considering the size of the volume. It is excellent as a student's text-book.

Der Drehstrommotor. By Julius Heubach. Berlin: Julius Springer. 356 pages, 163 illustrations. Price, 10 marks.

This text-book on the rotary field, polyphase induction machine is divided into fifteen chapters which relate to the working theory of the induction motor, with the exception of one chapter which deals with the induction generator.

The treatment is both by diagrams and by algebra, mingled with a few arithmetical cases. The treatment is lucid, the text and diagrams clear and the notation methodical. The vector method of diagrams is applied to the illustrations, but the complex vector treatment is scarcely alluded to in the text. The algebraical analysis is consequently different from that usually employed in the United States.

As a text-book by an engineer for engineers on the single-phase, two-phase, three-phase and polyphase induction machine, the book will have much value. Two chapters are devoted to details of practical construction, and a good index concludes the work.

Laboratory Exercises. Primary and Storage Batteries. By Karl E. Guthe, Ph.D. Ann Arbor, Mich.: George Wahr. 58 pages, 18 illustrations.

This is a small laboratory manual, intended to supplement the study of Carhart's well-known textbook on primary batteries. The laboratory course is laid out for students of electrical engineering, so that advanced exercises which would belong more properly to a course of elechrochemistry have been omitted. Nevertheless, the principal electrochemical problems are well placed before the students. The experiments in the first chapter, intended to show the difference of the conditions under which a system made up of the same chemical substances, may give a thermochemical or an electrochemical reaction, are especially very instructive.

The book is divided into four chapters, the first dealing with preliminary exercises and containing general useful information (for instance, on the purification of mercury). The second deals with the different methods of measuring the e.m.f., the temperature coefficient and the polarization e.m.f. of the cell. The third chapter treats of the methods for measuring the internal resistance, and the fourth chapter deals with time tests. The exercises described in the little book should enable a student to make complete tests of a battery, so that, besides its use for universities, the book may be recommended to any one who intends to enter the employment of a storage battery company, and also to those engineers who are using storage batteries in practice and desire to test their batteries themselves.

A Text-Book of Electrical Machinery. Volume I. Electric, Magnetic and Electrostatic Circuits. By Harris J. Ryan, M.E.; Henry H. Norris, M.E., and George L. Hoxie, M.M.E., Ph.D. New York: John Wiley & Sons.

Prof. Ryan's writings have always interested electrical engineers, and the text-book of which the first volume has just been published under his editorship will prove no exception. In clear, concise language the writers lay before the student the elements of the theory of alternating currents in a manner which, in spite of its simplicity, does not lack scientific rigor and accuracy.

The contents of the first volume are divided into ten chapters, headed: "Electricity and Magnetism," "Fundamental and Derived Units," "Periodic Curves," "Complex Quantities," "Laws of the Electric Circuit," "Electric Power," "Magnetomotive Force and the Laws of the Magnetic Circuit," "Rotating Magnetic Fields," "The Electrostatic Field," and "Losses in Electric Circuits." The chapters on units, on complex quantities, on electric circuits, consisting of resistance, inductance and capacity, are written with a didactic skill which deserves our greatest admiration. The chapters on periodic curves, on losses in electric circuits, seem altogether too brief and incomplete. It is much to be desired that the subject of Fourier series be treated by the teacher of electrical engineering rather than by the mathematician, as the wide field of application at the disposal of the engineer is generally a book with seven seals to the mathematician; and if interesting examples are held out to the student as the goal which he can reach only by wading through a mathematical bog, he is much more likely to keep up his courage than he will if he does not know the value and power of the mathematics, which he finds wearisome to study. In the chapter on losses in electric circuits, it is to be deplored that the writers do not give a simple derivation for the electrostatic capacity of parallel wires, as was given by Baum and Perrine in their paper in the *Transactions* of the American Institute of Electrical Engineers, May 18, 1900. The method which Baum and Perrine employ in their paper seems to us to deserve careful attention, and it should be embodied in any text-book in which the electrostatic capacity of long conductors is treated.

It is to be hoped that the remaining volumes of this useful and timely work will soon come out.

The Electric Drive as Applied in a Modern Machine Shop.

The general adoption of the electric drive is a conspicuous feature in the design of modern industrial establishments. A notable installation is the West Allis plant of the Allis-Chalmers Company. As the product of the company, as is well known, consists of the Reynolds type of Corliss engines for all power purposes, pumping and hoisting engines, also flour mill, saw mill and mining machinery, the electric drive is applied principally to the driving of machine tools and the installation, as a consequence, is characteristic of that class of work.

The West Allis plant has been built to increase the capacity of the company's plants and to provide for the future growth, although all of those which were already in operation have been continued. As is well known, these include the Reliance Works, of the former Ed. P. Allis Company, at Milwaukee, the Fraser-Chalmers and the Gates Iron Works, at Chicago, and the works of the Dickson Manufacturing Company, at Scranton, Pa. It is not the intention of the company to supersede the latter, but to confine all future growth to the new plant. Under the conditions existing at the later, and with the modern methods and means employed, the company's product can be manufactured at that point more economically than elsewhere.

The works are situated at West Allis, a suburb of Milwaukee. Two suburban electric lines pass the plant, which is also reached by spur lines of the Chicago, Milwaukee & St. Paul and the Chicago & Northwestern Railroads. As a consequence, skilled labor is readily obtainable from the latter place and has obviated the necessity of building a village for the accommodation of the workmen employed in the shops. The facilities afforded by the connection with the two trunk lines are such that raw materials are readily obtained and the manufactured product shipped to its destination. The site secured contains 100 acres, the plot being about one-half mile wide, and more than one-third mile wide. The soil is a firm clay and has afforded a most excellent foundation for the erection of the buildings and the machinery. It will be possible, because of the extent of the grounds, to increase the capacity of the present plant materially without in any way changing the present lay-out.

In considering the design of the West Allis plant, Mr. Edwin Reynolds, the consulting engineer of the company, decided that the arrangement of the buildings should be such that at whatever time an extension of the plant might be considered, the latter would always constitute a complete unit. It was furthermore deemed advisable that the building of such extensions should in no way interfere with the operation of the plant then existing. These may be considered the governing principles in the design of the plant, although a number of other features have been incorporated, which from an economical standpoint are desirable. To assist in the handling of the material in the various stages of manufacture, the buildings and the equipment have been arranged in such a manner that the least amount of labor is required for the production of a given amount of machinery. This is facilitated by a system of yard tracks connecting with spurs from the railroads and the extensive use of cranes, both in the buildings and in the yards. In fact, the latter feature is a noticeable one in the design of the plant; more than two miles of crane runway have been installed, and some 50 cranes, varying in capacity from one-half to 75 tons, of the traveling, jib, pillar and wall type, are in service. Of these four traveling, ten jib and four pillar cranes were supplied by the Northern Engineering Works. One of the cranes is of Shaw make. The balance of the equipment was furnished by Pawling & Harnischfeger.

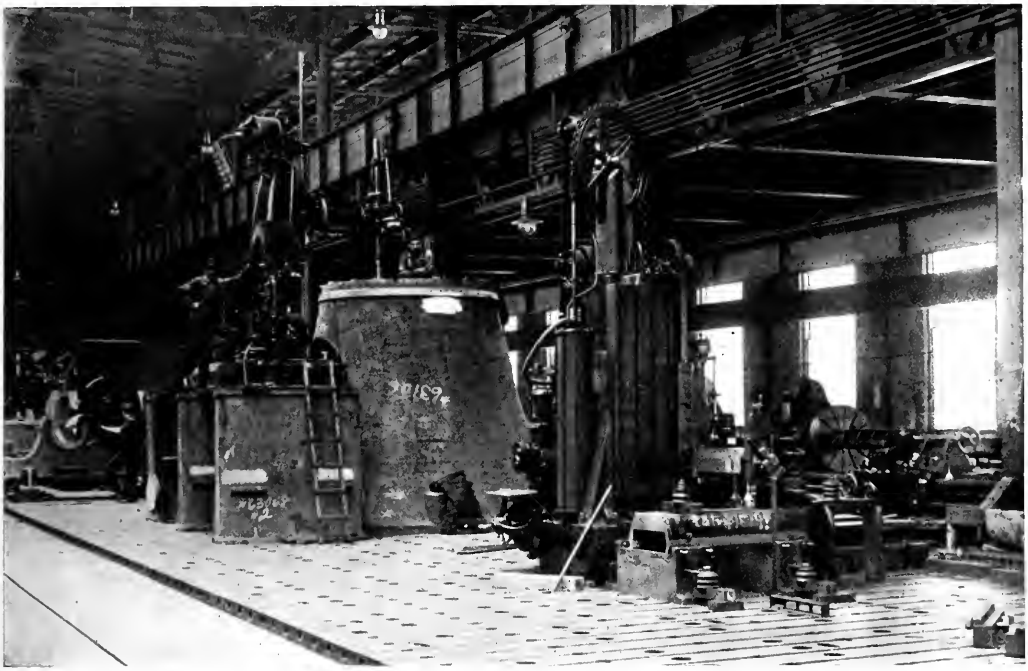

FIG. 1.—ARC LIGHTS FOR TROLLEY AND CRANES. FLOOR PLATE WITH PORTABLE TOOLS IN MACHINE SHOP.

The buildings include at present a storage and pattern shop, a foundry, a blacksmith shop, two machine shops and an erecting shop. Space has been utilized in the blacksmith shop for the power house, which thus is centrally located with respect to the buildings which it serves.

All of the works buildings, with the exception of the machine and the blacksmith shops, are erected in parallel lines, whereas the latter are at right angles with and communicate with the erecting shop. In making extensions, additions will be merely added to the former, but new buildings will have to be erected for the machine and blacksmith shops. In either case it will be seen that such operations will in no way interfere with the manufacturing which is being conducted in the sections previously erected. This is quite important when it is considered that during the erection of such additions, the capacity of the plant will not be cut down and as soon as the additions are completed the output of the plant will at once increase in the same proportion as the increase in capacity.

The buildings are of the steel skeleton, brick curtain wall type of construction, a center bay, with a lean-to on each side, being adopted. The advantages of such a type of buildings have been availed of to place the heavier tools in the main bays, which are commanded by traveling cranes and spur tracks which permit the handling of large and heavy material readily.

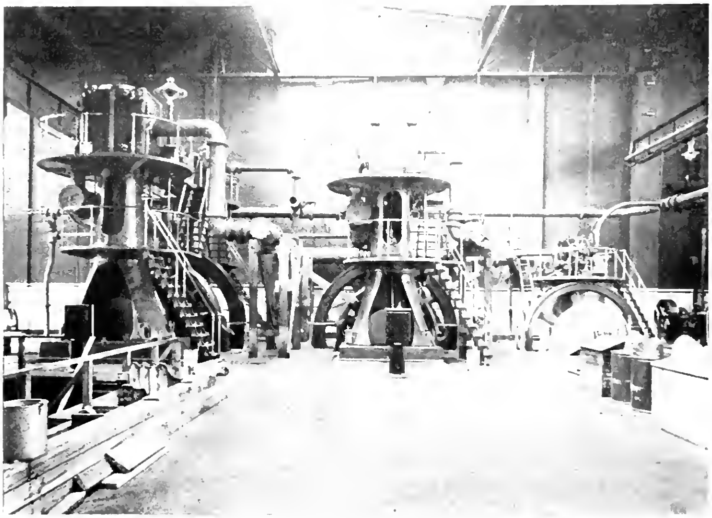

FIG. 2.—INTERIOR VIEW OF POWER PLANT.

The electric drive has been of material assistance in the lighting of the shops, which is further increased by large window areas. Although the buildings have been made as fire-resisting as possible, special attention has been paid to this in the case of the pattern storage building. This is four stories in height, whereas the pattern shop, which is built as a lean-to to it, is but one story in height. Concrete floors are used throughout and fire walls divide the building into sections. The windows consist of wire glass in iron frames, and the roof is covered with the H. W. Johns-Manville Company's asbestos roofing. The various buildings are separated from one another by ground areas of such extent as to serve as storage places for material.

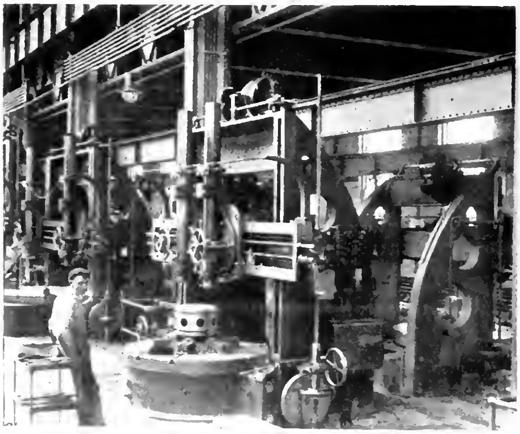

FIG. 3.—ELECTRICALLY-DRIVEN BORING MILLS.

The power scheme for the works is of unusual interest, as revealing a tendency to depart from generally accepted practice. Whether in the construction of power plants for electric light stations or for industrial establishments, it has been the usual course to unite all sources of power in one location. In this instance, however, the works as laid out will eventually have two independent power plants. Such a course has been deemed advisable as certainty of operation has been considered of greater importance than any economy which might result from the concentration of the two plants in one. It, of course, will be readily appreciated that power in such an establishment, although not an insignificant item in the cost of production, nevertheless is not the most important one. Although with modern motor-driven tools, the possibility of a shut-down is not as great as formerly with line shaft-driven machinery; nevertheless, the possibility of an accident to the power plant itself is a factor not to be disregarded,

Except in a few cases where it was not advantageous to do so, the electric drive has been used exclusively. As a large part of the machinery consists of variable-speed tools, and also because of the extensive use of cranes, direct current has been used exclusively. Current is generated at the power house at 250 volts and by means of compensators, a voltage of 110 and 220 is maintained on a three-wire system for the lighting load. For power work, the four-wire system of the Bullock Electric Company is used, balancing sets being installed in the various buildings to furnish the several voltages required. Compressed air is furnished for a few pneumatic tools, where electrically-operated tools would not meet the requirements. Hydraulic power is also used for several of the elevators, but in such cases electrically-operated pumps have been installed at the point where the power is required.

The power house, as already noted, is located in a part of the building devoted to the blacksmith shop. The boiler room at present contains five 300-hp, 96-in. x 24-ft. Reynolds vertical tubular boilers. Provision has been made for installing coal-handling apparatus and mechanical stokers. Coal is delivered in the boiler room on cars run in on a spur track which connects with the general yard system. Steam is generated at 125 pounds and aside from the engine room is also supplied to several steam hammers in the blacksmith shop. An 8-ft. stack, 175 ft. high, of the Alphons-Custodis Construction Company's type, has been built.

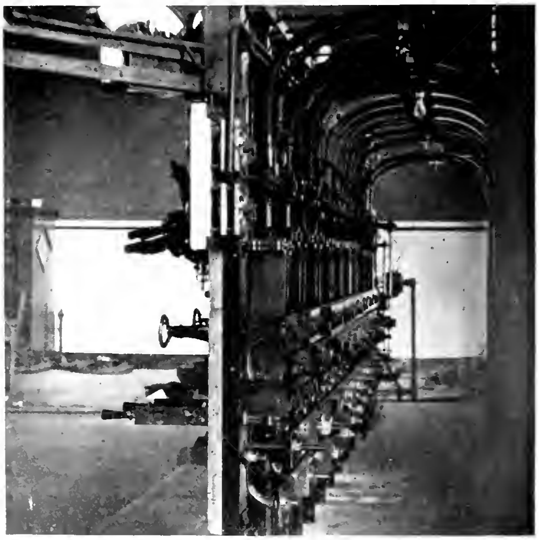

FIG. 4.—REAR OF SWITCHBOARD IN POWER HOUSE.

The engine room contains one 550, one 250 and one 100-kw direct-connected unit, with space for two additional 550-kw units. The engines are of the Reynolds-Corliss vertical type, made by the Allis-Chalmers Company. The smaller engine, although of only 100-kw capacity, has been especially built to conform to the larger units, in type and speed. The engines are non-condensing, the exhaust being used in a hot water heating system, installed by Evans, Almirall & Co. The generators are 250-volt machines, of General Electric and Crocker-Wheeler make. Two Bullock compensators of 12½-kw capacity are installed to maintain the neutral of the lighting system.

The switchboard, although not embodying any unusual features, is of a most substantial construction. Special attention has been given to the finish of the various instruments and the apparatus which has been used in its construction. The special castings which have been used for connecting switch and instrument lugs with the various bus-bars are of special design, and have been buffed so as to receive a high polish. Pressure and other wires on the back of the board are carried in pipes to various points as required. Two sets of bus-bars are provided, so that if necessary the lighting and power circuits can be operated independently of each other. In the generator and the power circuits both switches and circuit-breakers have been employed, whereas for the lighting circuits switches are dispensed with entirely. In order to obtain as compact a board as possible, the I. T. E. circuit-breakers were specially constructed for this installation. The main coil, switch and tripping devices are in line and are operated in gangs of two or three, as required by the various circuits. A Thomson recording wattmeter measures the output of the station; a Bristol recording voltmeter has been installed to record the fluctuation in the voltage on the lighting circuits. The instruments and switches are all of antique copper finish as well as the grill, which is seen below. The switchboard was designed by Mr. Alvan Dings, the electrical engineer of

FIG. 5.—CONTROLLER AND AMMETER MOUNTED ON BORING MILL.

the company, and was made by the Milwaukee Electric Railway & Light Company.

Separate feeders are provided for the power and the lighting load for each building. The feeders consist of Standard Underground and General Electric lead-covered, paper-insulated cables, drawn into a conduit system built of Camp tile; 70 ducts leave the station. The underground system is built in a most approved manner and conforms to the practice of the larger electric lighting companies. The conduit is run into the various buildings to a point level with the floors and after the cables have been pulled in is closed up so that foreign objects cannot be introduced. The cable rack at the station, although built of iron, is covered with split tile, so as to afford sufficient insulation for the cables.

The various buildings are lighted by incandescent and constant-potential arc lamps. The latter are hung in alternate panels on each side of the main bays of the various buildings. In the machine and erecting shops arc lamps have also been hung to light the galleries. This doubles the illumination of the main bays as compared with the lean-tos or the galleries. Incandescent lamps either as pendants or in fixtures are distributed wherever required. To

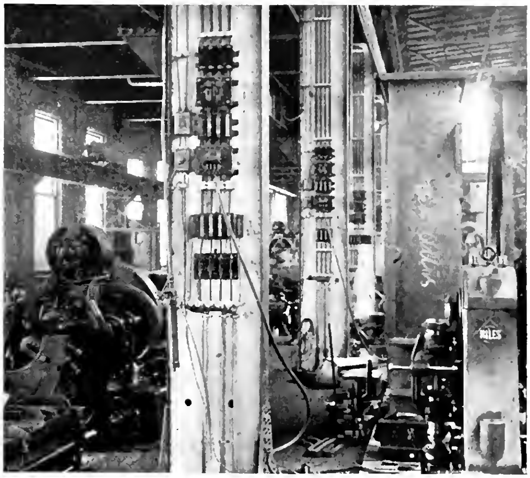

FIG. 6.—POWER CIRCUITS FOR PORTABLE TOOLS.

facilitate work, especially on the larger tools, one or more receptacles are placed on each column, thus permitting the use of extension cords.

The lighting feeders for each building, as already noted, are run independently of the power circuits, directly from the switchboard in the power house to a panelboard installed in each lean-to of each building. From this board circuits are run to various panelboards which control the incandescent and the arc lamps in any one part of a building. The incandescent lamps are controlled from panelboards, of which there are two to each floor and each side of a building. The corresponding arc lamps, however, are controlled from but one such board. All circuits are fused, including the neutral, but not the latter at the centers of distribution. Any section of a building can thus be readily cut out or lighted at will. Enclosed fuses are used exclusively and are refilled by the company's employees. A small repair shop is maintained in which all work required, either for the repair of a motor or any other part of the electric installation, can be readily attended to. The general lighting of the buildings is of the best nature, as very little fluctuation occurs in the voltage due to variations in current for the power circuits, even with the number of cranes which are constantly in operation. The arc lamps are partly of General Electric make, whereas the balance were furnished by the General Incandescent Arc Light Company.

The power feeder for each building is run to a center of distribution, at which the balancing sets for the Bullock four-wire system are installed. As will be seen from the accompanying photograph, the switchboard installed at such points contains the necessary switching apparatus and meters. The ammeters of which one is installed in each leg of the four-wire system are of the differential type, so that the amount of power and the unbalancing in each circuit can be readily determined. The Bullock four-wire system, as is well known, gives six voltages. To prevent mistakes being made, a code has been adopted whereby the east, south and upper wires are always positive. All wiring below and to a distance of several feet above the floor is run in Richmond conduit. For all machinery permanently installed, the wires are run through conduit to such machines. For portable tools, a special receptacle has been installed on the building columns to permit of power being delivered wherever required. As will be seen in the accompanying illustration, the north side of each column has been covered with dressed boards, to which the wiring and other apparatus is firmly attached, and which at the same time serve as insulation. The receptacles for power work deserve special mention, as it was found necessary to develop a design which would meet the conditions existing at the plant. These will not heat with any current required for operating the tools. Their construction, furthermore, is such that the plug must always be inserted in the same way, which prevents a motor from being connected up in any other than the proper way, and without any special thought on the part of the men.

The larger motors of the variable-speed type are equipped with a Bullock controller and, in addition, with an I. T. E. circuit-breaker and a Jewell ammeter. As the frequent blowing of a fuse has been found objectionable, circuit-breakers were installed, which, of course, can readily be closed when the circuit is opened. The ammeters serve a most useful purpose in showing the workman the load which he is carrying, and thus permit the carrying of an overload within limits when necessary, without opening the circuit-breaker. The ammeter reading also at all times indicates whether or not the workman is working his machine to its full capacity. The controllers are placed at such points or mounted directly on the machines, so that the workman at all times can start or stop the machine readily. In the case of lathes with very long ways, the controller can be operated from the tool rest through a spline shaft. In the latter case, a separate series motor has also been provided for operating the carriage travel. In the case of lathes and some other machinery, motors have also been provided for actuating pumps delivering soda water, etc., to the tools.

In nearly every case, each tool is operated by its own independent motor. Group drives have been used in but a few cases where the tools would not readily permit of any other arrangement. In the case of the larger tools, as the boring mills, several planers, etc., two and three motors are provided for various operations. In a great many of the tools the motors are mounted directly on these and drive the former through gears. In other cases the motors, although mounted on the machines, are belted to these, whereas in several instances the motors are placed at some convenient point. Bullock motors are used on the multiple voltage system. Because of the inability to obtain equipment as required, motors of nearly every make are used throughout the plant.

The feeders for the cranes are taken from the centers of distribution in the various buildings without the intervention of switches or circuit-breakers except those at the power house and the circuit-breaker installed on the cranes themselves. One trolley wire which is of the figure 8 section, is placed on each side of the crane runway. A feeder is tapped into this at about a quarter of the distance from each end and every 75 ft. between. The trolley wires are fastened with giant strain insulators and eye bolts and supported every 20 ft. by a clamp fastened to a bolt which has a vertical movement. The bolt is insulated by fibre from the supporting bracket and the whole is fastened to a wood block, secured to the girder runway. In the yards a similar construction is used, with the exception of an insulating bell in place of the giant strain insulators. The collecting wheels on the cranes pick up the trolley wire, thus preventing any serious strains on the latter and also any undesirable flashing. The crane equipment proper is of standard make as supplied with the cranes by the various manufacturers.

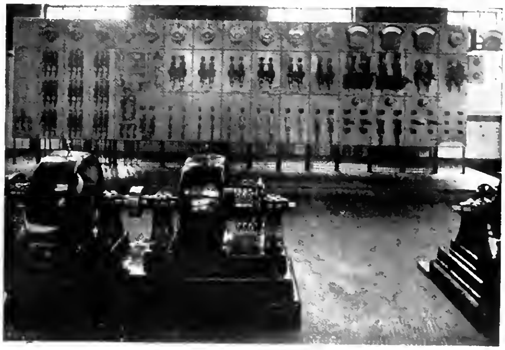

FIG. 7.—SWITCHBOARD AND BALANCING SETS.

A five-ton electric telpher furnished by Pawling & Harnischfeger, has been installed in the pattern shop to facilitate the handling of patterns within the building.

The feed water pumps in the power house are electric-driven. The operation of these has been made automatic in the following manner: In a by-pass around the pump, which connects with the source of supply and the boiler feed pipe, a valve is inserted, which is operated at a higher pressure than that which is maintained in the boilers. As the pressure in the boilers increases, the pump which operates continuously, increases the pressure in the by-pass until it opens the valve located in the same. This, of course, is a waste of energy, as the pump then merely circulates the water in a circle. To prevent this a gauge similar to a steam gauge, which is provided with two concentric rings, has been connected in the by-pass. As the pressure increases the pointer finally reaches a point where it closes a secondary circuit, which in turn opens the motor circuit.

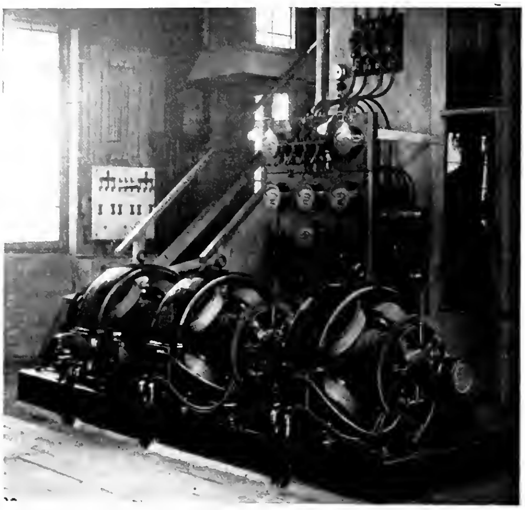

FIG. 8.—BALANCING SET AND SWITCHBOARD.

Several deep well pumps, made by the Downing Pump Company, which are installed at several artesian wells on the company's property, are operated automatically by Cutler-Hammer switches, which are actuated by floats, placed in several cisterns near the power house.

Various tools used about the plant are also electrically operated, among which may be mentioned electric drills of the Hisey-Wolf Machine Company; electric drills, center grinders and hack saws, made by James Clark, Jr., & Co., and babbitt melters and glue pot heaters, made by the United Electric Heater Company. The cranes operated in the yards are heated by electric heaters furnished by the same company. Several portable sand sifters and mold drivers are also electrically operated.

New Sturtevant Plant.

One of the features of the new plant of the B. F. Sturtevant Company, at Hyde Park, Mass., peculiarly indicative of the permanent character of the new works now under construction, is the steam tunnel 4½ ft. in width and 6½ ft. high, extending from the power plant to the most remote part of the manufacturing buildings, a total distance of about 800 ft. The tunnel, which is of concrete construction, will not only accommodate all of the steam piping, but also the electric wires for power, light, telephone, standard time clock, and other service, together with oil, hot water and other pipes for general distribution to the various buildings of the plant. None of these features of the equipment will be carried above ground at any outdoor point.

The New York Automobile Show.

This is Automobile week in New York City, and the fact is as palpable and evident as Horse Show week is. Uptown, particularly in the vicinity of Madison Square Garden, the automobile is conspicuously numerous, while in every hotel, restaurant and café of the fashionable quarter well-known automobilists are to be seen aplenty. As for the Garden itself, the show given there under the auspices of the Automobile Club of America and the National Association of Automobile Manufacturers, is a brilliant success. The fourth annual show is an advance over all its predecessors in the shape of exhibits, attendance, sales and general public interest, although it cannot be said that any particular novelty is to be encountered. In fact, the art would appear to have become rapidly standardized in regard to many of its essentials, and freak ideas or machines are disappearing. The present show closing to-night, Saturday, has had on view, aside from innumerable specialties and supplies ranging from sprocket chains to goggles, no fewer than 250 automobiles, including 181 gasoline, 46 electrics, 11 steam and 12 motor cycles. These figures represent very closely the relative magnitude and importance of the three motive powers, as thus far developed, though it is probable that no one would predict very boldly as to their ratio in the years to come. A great many of the electric automobiles shown are of the commercial type, an encouraging fact for the builders and for the manufacturers of storage batteries. We illustrate herewith some of the leading groups of electrics.

The Edison Storage Battery Company had a very interesting exhibit of a set of 20 of its cells in a Baker Electric Stanhope, which was exhibited under the competent charge of Mr. Bee, who stated in connection with this set that owing to recent improvements Mr. Edison has again greatly increased the capacity of the cell, adding to its desirability for automobile work.

The Electric Storage Battery Company of America had a small but adequate and interesting exhibit in the space of the Electric Vehicle Company. It showed three types of cell, chief of which was the express cell intended specially for heavy work, such as drays, trucks, etc. This battery was opened up so that the interior construction and the nature of the basswood and rubber separators, etc., could be observed. The lugs on the plates are extremely substantial and heavy. The second type shown was the latest form with heavy lugs for ordinary automobile work, and the third type was a very compact little set devised for sparking purposes on gasoline and other hydrocarbon vehicles. All of these are in extensive use to-day. Other sets of Electric Storage Battery Company's cells were to be found around the exhibition, notably one in the space of the General Electric Company, being charged by means of alternating current taken through a mercury arc rectifier.

The General Electric Company had a most interesting and comprehensive exhibit at the Fourth Avenue end of the hall, comprising its new motors, controller, panelboard, etc., details of which are given elsewhere in this issue, and particularly its novel form of mercury arc rectifier. Under the care of Mr. A. Churchward a set

Fig. 2.—Exhibit of National Electric Automobiles.

was shown of apparatus including a rotary reversed, taking the direct current of the house and delivering single-phase current to the mercury arc rectifier, whose operation could be witnessed through glass. This rectifier straightened out the current and delivered it to a set of Exide cells and the quantity of current going into the battery could be noted from the indicating instruments on the board. This attracted a great deal of attention, especially as experiments were made to show flexibility under a range of frequency and under other varying conditions. Mr. Churchward stated that he had been charging storage batteries for practical work in this way for six months past.

Fig. 1.—General View of the Automobile Show, Madison Square Garden, New York.

THE BAKER ELECTRIC VEHICLE COMPANY had a very interesting display, containing possibly the greatest novelty in the direction of electric vehicles, one with the Elwell-Parker motor placed in the front hood usually occupied by the gasoline engine and driving at right angles on the axle shaft by means of beveled gearing. The vehicle was a surrey equipped with a $2\frac{1}{2}$-hp motor and 24 cells of storage battery.

THE ELECTRIC CONTRACT COMPANY showed a line of its dry batteries and sparking outfits. The exhibit was in charge of Mr. Skinner.

FIG. 3.—BAKER ELECTRIC VEHICLE EXHIBIT.

MEYROWITZ MANUFACTURING COMPANY had an exhibit of eye glasses and shades for automobilists.

DAYTON ELECTRIC MANUFACTURING COMPANY showed the Apple Igniter, which has become so deservedly popular for sparking purposes on gasoline vehicles.

NATIONAL CARBON COMPANY batteries, etc., were shown in a handsome booth.

FIG. 4.—EXHIBIT OF ELECTRIC VEHICLE COMPANY.

DOW PORTABLE ELECTRIC COMPANY, Boston, had dry batteries and sparking outfits on exhibition.

C. F. SPLITDORF showed his well-known coils in a well-arranged exhibit.

MR. F. A. LA ROCHE, the well-known electrical manufacturer, showed a full line of French Darracq automobiles for which he is American representative.

EMIL GROSSMAN showed a line of jacks. He was admirably represented by Harry M. Shaw, well known in electrical circles.

MESSRS. A. G. HYDE AND WALLACE L. HOWARD represented the Whitlock Coil Pipe Company, of Hartford, Conn.

THE UNITED ELECTRICAL MANUFACTURING COMPANY had dry batteries on exhibition.

MESSRS. RUSHMORE AND POINER, of the Rushmore Dynamo Works, exhibited their searchlights, which are finding extensive use on automobiles.

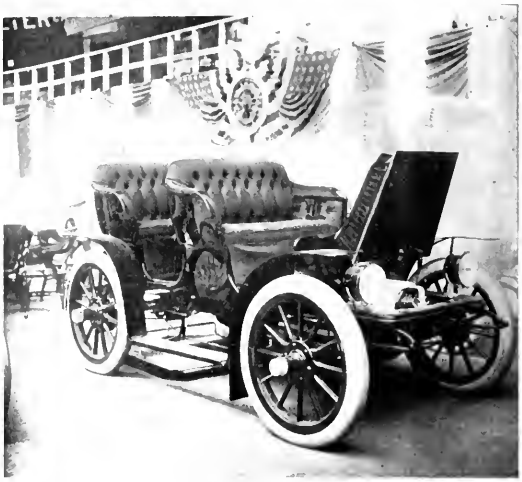

FIG. 5.—NEW TYPE OF ELECTRIC AUTOMOBILE.

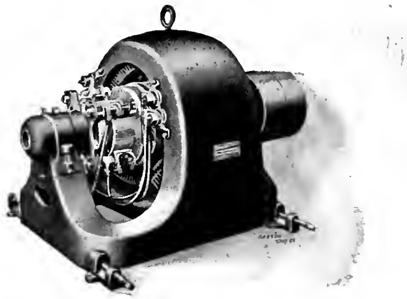
Direct Current Dynamos and Motors.

A line of direct-current machines, of bipolar and multipolar design, is being introduced by the Hertner Electric Company, of Cleveland, Ohio. These machines range in sizes from ¼ to 15 hp and are adapted for lighting, power and elevator work. Electrically the intention of the designers seems to have been directed towards making the magnetic circuit of the field as stiff as possible, resulting in a decrease in the speed or armature turns, or both, to the great advantage of the overload capacity of the machines. In most respects the design is similar to that of standard machines now on the market, particular attention being paid to the production of a mechanically symmetrical construction. Several novel devices are resorted to in order to insure perfect freedom from oil on the inside of the commutator. The company is making a specialty of furnishing motors for extraordinary service.



DIRECT-CURRENT MACHINE.

These machines, it is stated, have been used with marked success in certain classes of printing press work where the speed variations are wide. The brush-holder is of a somewhat novel type. It is claimed that it overcomes the chattering of the brushes and the sticking to the face of the holder. The only moving parts are the brush and a very light finger, so that the motion of the commutator will be readily followed.

General Electric Exhibits at the New York Automobile Show.

The exhibit at the show of the General Electric Company were electric motors of new and improved design, a motor-generator charging set, a large and small Lemp steering check, a controller for electric vehicles using one motor, a standard controller for electric vehicles using two-motor equipments, a charging panel, a switchboard, a single-phase rotary converter and a mercury rectifier. The exhibit occupied a space at the right-hand corner of the south aisle at the Fourth Avenue end of the Garden and was handsomely decorated.

It is obvious that where the power to run the motor is derived from batteries carried in the vehicle and not from practically an unlimited source of power, such as the overhead trolley supplies, that the electrical qualities of such a motor should receive very careful attention. The qualities are of low cost and light weight, of course, desirable but not at the expense of high torque efficiency and proper speed characteristics at all loads. If the motor be too light it lacks proper structural strength, and its life is consequently short. If a motor is to have the proper electrical efficiency a certain amount of iron and copper must be provided in order to obtain increase of torque for the given current input and decreased heating effected.

The new six-pole General Electric automobile motor known as the G.E.-1010 and G.E.-1011, now exhibited for the first time, approaches very nearly to theoretical possibilities in its speed, torque and efficiency characteristics and the relationship between them. The torque for a given current is relatively high and increases in correct proportion as the current increases. It also keeps up its efficiency when a large torque is required, such as starting, hill climbing or running on bad or muddy roads. The field rings of this new class of motors are made of cast steel. The pole pieces are of laminated iron and the coils are machine wound and thoroughly water-proof. The commutator segments of the armatures are deep and wide, giving high conductivity and perfect radiation of heat at overloads as well as insuring long life and freedom from sparking.

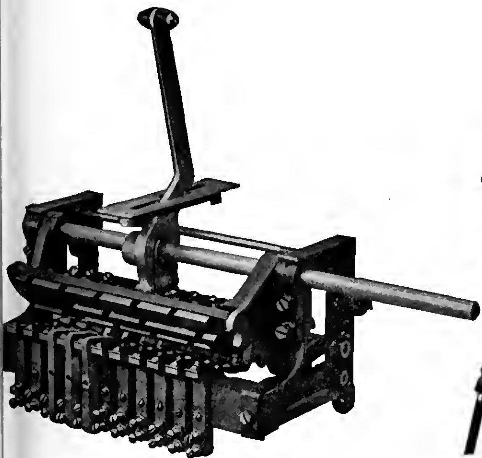


FIG. 1.—CONTROLLER.

FIG. 2.—CHARGING PANEL.

FIG. 3.—MOTOR.

In order to decrease the cost of repairs, the armatures of these motors have been built on quills so as to facilitate removal. The oil ring bearings have been standardized in a form similar to those so successfully employed in street railway service. The shafts have been made of a specially high grade of steel, and the journals are large, insuring minimum attention, and are protected from dirt and grit by a perfected form of dust-proof packing.

As many parts as possible of these new motors have been standardized and are, therefore, interchangeable. Any size of motor may be fitted with or without axle arms, according to the desire of the customer as to the method of suspension.

The charging panel shown in the General Electric Company's exhibit is fitted for one 2-hp, three-phase, 60-cycle induction motor connected to 1-kw, 110-volt generator. The equipment of this panel consists of a four-pole circuit-breaker, two lamps with bases to be used as polarity indicators, one pocket voltmeter, 10-amp. capacity; one pocket voltmeter, with 120-volts capacity; one starting rheostat, two fuses, one plug switch and one resistance for low-voltage coil.

To supply the demand for a small charging set for automobiles,

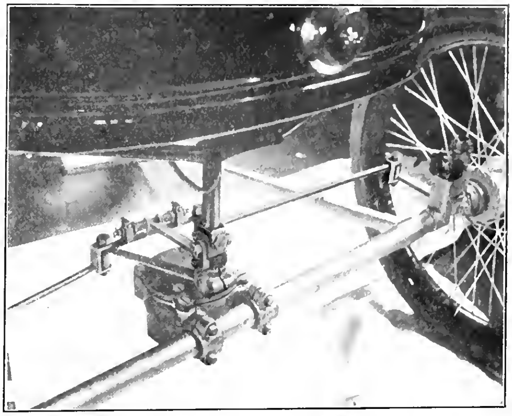

FIG. 4.—STEERING CHECK.

that can be operated by any standard single-phase circuit, the General Electric Company has placed on the market a single-phase self-starting rotary transformer that can be operated successfully on both 60 and 133-cycle circuits. This type of single-phase rotary is self-starting, with less than full-load current, and the starting mechanism is automatically changed from the starting to the synchronous running position.

Up to the present time it has not been possible to build an efficient and satisfactory single-phase rotary transformer without the use of some dampening or anti-hunting device. The Churchward anti-hunting device has been in successful operation for a number of years, both 60 and 133-cycle rotaries operating on single, two and three-phase currents. All these new single-phase rotaries are equipped with the latest improvements on this device. The present standard outfit will give the following range of e.m.f. without the use of resistance: 90-120 volts, 45-60 volts at full load.

For localities where the owner of a small electric automobile has great difficulty in arranging charging facilities, or the expense and care of a gas engine or motor-generator is too great to be considered the General Electric Company has developed a mercury arc rectifier suitable for charging the common runabout of 20 to 30 cells under all ordinary conditions of usage. The two principal features of the rectifier outfit are, first, a vacuum tube in which the conversion takes place, and, second, a reactance, the function of which is to secure stability of operation and to give a ready means of varying the load. The operation of the rectifier is most simple. On inserting the battery plug and closing the line switch, the vacuum tube automatically lights, and as soon as lighted the battery begins to receive its charge, the amount of current being regulated by the dial switch on the face of the compensating reactance mounted on the top of the panel. The capacity of this rectifier is 10 amp., this being a rate of charge at which an automobile, in case it is fully run down, may safely be left charging all night. Inasmuch as the rectifier is so simple to operate and requires no attention, there should be little excuse for vehicle owners ever being caught with an empty battery. If, during the time of charging, the power should go off, charging ceases, to automatically recommence as soon as the circuit becomes alive again.

Resistances in Telephone and Telegraph Practice.

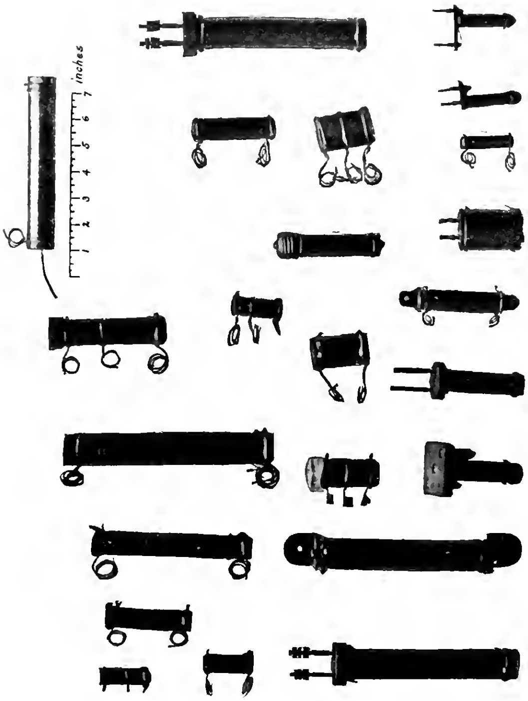
As the telephone and telegraph service is of vital importance in quick modern business transactions, anything which promises increased efficiency in this service is worthy of being given the closest investigation and of having the best engineering talent devoted to the solution of the questions involved. The Ward Leonard Electric Company has devoted its attention to the specific task of producing a compact unit, of high resistance and moderate current-carrying capacity, combining in a small space the salient features of a strong, durable telephone or telegraph resistance unit.

The cuts show units made of wire enameled on porcelain tubes, possessing the following advantageous features: The resistance wire is imbedded in a material which will expand and contract at the same rate as the resistance itself within the limits of usage, thus preventing the adjacent coils from closing together and short-circuiting, preventing, therefore, a change in the resistance of the unit which might cause a burn-out in the circuit. The enamel in which the wire is imbedded and by which it is entirely covered, protects the wire from the atmosphere. As the entire wire is hermetically sealed, it cannot deteriorate owing to the action of moisture or other corrosive elements. The coating of enamel over the wire is so thin and the enamel so good a conductor of heat that the heat generated is dissipated very rapidly because the radiating surface is practically increased from that of the fine wire to that of the porcelain tube. The resistance wire has a zero temperature coefficient, that is, its resistance, does not alter with change of temperature, the importance of which is well known.

These units are very strong mechanically, are small, compact, non-abrasive, rust-proof, water-proof, fire-proof and dust-proof. The terminals are very strong and the connection between the resistance wire and the terminal head is embedded in the enamel, which preserves the joint against any depreciation. The shape is the best possible for mounting in practice, as will be evident from the cut, which shows units designed for mounting in cord circuits in telephone exchanges. They are 2 in. long by ½ in. diameter and can be wound for any resistance from five ohms to three-hundred.

The cut also shows units designed for ringing circuits in telephone exchanges. The resistances are 3¼ in. long by ¾ in. diameter. They can be wound for any resistance from five ohms to seven hundred ohms. The cut shows 650-ohm units arranged for mounting in Edison sockets, mounting against the wall of a section or for mounting on a slate panel.

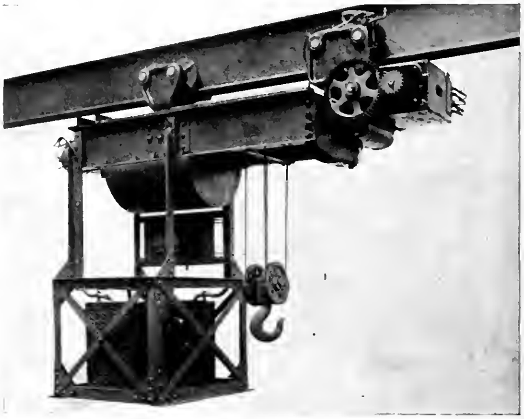
Ward Leonard Electric Company's engineers solicit the opinion of telephone and telegraph men and would gladly take up any problems of design, mountings, etc., which they may suggest. The Postal Telegraph Company, always progressive, has adopted these units of a larger size for their circuits and in the construction of their rheostats.



RESISTANCE COILS.

Electric Traveling Hoist.

The engraving herewith illustrates the new electric traveling hoist built by the Niles-Bement-Pond Company, of New York, at its Philadelphia crane department. These hoists may be equipped with a cage as shown, or may be arranged to be operated from the floor by means of pendant controllers. The hoisting mechanism is placed between the channel framing of the trolley and is direct-geared to the drum, a standard load and motor brake being provided. Power for hoisting, in all cases, is furnished by electric motors, while the trolley travel may be arranged for by motor or hand racking. This type of hoist is built in three sizes of three, four and ten-tons capacity. Swivel trucks will be furnished for use on curved tracks.



ELECTRIC TRAVELING HOIST.

New Engineering Firm.

The Beardsworth Engineering & Machinery Company, Cleveland, Ohio, has been formed to act as electrical engineer and selling agent for electrical equipment. The company will make a specialty of selling and re-installing complete second-hand power plants that are fully guaranteed by those who wish to dispose of the same. It has a number of complete plants for sale in various parts of the country. Parties having steam and electrical equipment too small for their present requirements can make advantageous exchanges through this company.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—The stock market was irregular in its tendencies, being influenced largely by the conflicting reports of the situation in the Far East, and the nervousness of the European markets. United States Steel issues were stronger, and Brooklyn Rapid Transit and similar stocks were rather heavy. The firmness in Steel preferred and sinking fund bonds was due to absorption from many sources, the West being again a liberal buyer. Tractions and Electrics were neglected, and weakness characterized the market for this class of securities. General Electric was almost entirely neglected, only 80 shares having been reported sold during the week. The price, however, kept quite steady, ranging from 173 to 175, and closing at 174. Westinghouse common closed at 168, being a loss of 4½ points net. Western Union closed at 87¾, which is ¼ point off. Commercial Cable, on sales of 546 shares, closed at 183½, this being a net gain of 15½ points. American Telegraph & Cable gained 3⅞, closing at 85⅞. Among the tractions Brooklyn Rapid Transit closed at 48½, a net loss of 2¼ points, the sales aggregating 73,100 shares. Metropolitan Street Railway closed at 121, a net loss of 1 point. In Boston notable strength was displayed at the end of the week in Massachusetts Electric, Edison Electric Illuminating and the copper shares, while the general market was steady. Following are the closing quotations at New York of January 19:

DIVIDENDS.—The directors of the American Light & Traction Company have declared the regular quarterly dividend of 1½ per cent. on the preferred stock, payable February 1. The directors of Allis-Chalmers have declared the regular quarterly dividend of 1¾ per cent. on the preferred stock. National Steel & Wire Company directors have declared the regular quarterly dividend of 1¾ per cent. on the preferred stock, payable February 3. The Chicago Edison Company has declared a quarterly dividend of 2 per cent., payable February 1, to holders of record January 23. The Central District & Printing Telegraph (Bell Telephone) Company has declared the regular quarterly dividend of 2 per cent., payable January 30. Electric Company of America directors have declared a dividend of 3 per cent. (30 cents per share), payable January 30. The Columbus (Ohio) Gaslight & Heating Company has declared a dividend of 4 per cent. on its common stock. The Minneapolis General Electric Company has declared a dividend of $3 per share.

THE "SOO" EDISON COMPANY.—Some important changes are to be noted in the personnel of the Edison Sault Electric Company, of Sault Ste. Marie, Mich. At the adjourned annual meeting held January 15, 1904, the following directors were elected: William Chandler, Sault Ste. Marie, Mich.; Henry W. Darling, Schenectady, N. Y.; Alex. Dow, Detroit, Mich.; Alfred Jeretzki, New York; Frank P. Sullivan, Sault Ste. Marie, Mich. The directors elected Mr. Alex. Dow as president and Mr. William Chandler as vice-president. Messrs. Dow, Jeretzki and Sullivan are new names on the board and represent a change of control of the property. Mr. Dow is to be the active representative of the new interests. Mr. Dow is widely known as a manager of other successful illuminating properties, more particularly the Edison system in Detroit. The stockholders at the same meeting authorized the increase of the capital stock of the company from $57,000 to $150,000.

CLARK WIRELESS TELEGRAPH.—At the meeting held last week, the following officers were elected for the coming year of the Thomas E. Clark Wireless Telegraph-Telephone Company: Thomas E. Clark, president, Detroit; Frank Ford, vice-president, Birmingham, Mich.; J. E. Sawyer, secretary, Pontiac, Mich.; Joshua Hill, treasurer, Pontiac; Wm. Barringer, assistant secretary, Pontiac; John Z. Hayes, director, Detroit; A. Stiling, director, Detroit. The further sale of treasury stock was voted upon, and it was agreed that $20,000 worth of the treasury stock should be sold, to increase working capital in order to care for the larger business which was coming to the company in the various lines of wireless telegraph instruments, as well as other electrical specialties.

STORAGE BATTERY OUTLOOK.—Advices from Philadelphia say: "An Electric Storage Battery director says the 1903 year's earnings ran about $4,000,000, the largest business the company ever did. Easily 10 per cent. can be shown earned on the stock. While, as a matter of fact, the company could have paid spot cash for the factory real estate it recently purchased, it was deemed best to accept other terms, because of easy payments with low interest rates."

AMERICAN GRAPHOPHONE.—The American Graphophone Company reports total income for the year of $659,513, and net of $270,266, out of which the preferred dividend takes $78,677, leaving a surplus of $191,589. Assets are put at $3,798,215 and liabilities offsetting, with surplus of $522,403.

SOUTHERN NEW ENGLAND BELL.—It is stated in New Haven dispatches that the directors of the Southern New England Telephone Company have voted to increase the capital stock from $3,500,000 to $4,000,000.

BOSTON EDISON EXTENSION.—The Edison Electric Illuminating Company, it is stated in Boston dispatches, has acquired the Somerville (Mass.) Electric Light Company, the consideration being $577,000.

Commercial Intelligence.

THE WEEK IN TRADE.—Spring trade shows signs of activity, and this, coupled with a large volume of clearance sales by retailers, gives evidence of brisk mid-winter operations. There is also an evident improvement in the industrial situation, particularly in iron and steel mill resumptions, and an active spring is looked for in this line. Reports from all sections of the country are favorable, and trade in all lines of commodities and products is cheerful and satisfactory. Foreign trade returns are gratifying. Export trade in 1903 swelled largely by the record-breaking value of cotton shipments, and aided also by large exports of beef cattle and expansion in exports of manufactured goods, broke all records, exceeding those of 1900 by a small percentage. Imports, too, were the largest on record, the result being a total foreign trade of $2,500,000,000, a sum exceeding all previous totals. The iron trade was irregular, but the outlook and conditions are regarded with favor. Production was the lowest for the past five years, although current resumptions will soon swell the output slightly. Finished products are also irregular. A sale of 20,000 tons of rails for Turkey is reported. Copper, lead and tin are all higher on reported good demand. In copper there was a strong effort to lift the market which resulted in higher quotations. There was little business, however. The closing quotations were 12¾c. for Lake, 12⅝c. for electrolytic and 12½c. for casting stock. There were 315 business failures during the week ending January 14, according to *Bradstreet's*, against 262 the week previous, and 234 the corresponding week last year.

ENGINE OUTLOOK.—An official of the Allis-Chalmers Company is quoted in Chicago as follows: "There has been a great deal of keen competition among builders of machinery during the last five or six months, and the new year has by no means eliminated the condition. Compared with a year ago prices are very much lower, and the volume of business available shows marked shrinkage in many lines, particularly that of heavy power engines such as are used by the public service companies of municipal corporations. These projects are very nearly all dependent upon the flotation of bonds and at the prevailing high rates for money it is practically impossible to carry out such plans. There are many projects planned, but held in abeyance because of these conditions. This company is getting its share of the business offering and our principal orders now are coming from the southwest, where milling and mining machinery is in fair demand. Old Mexico is also taking more modern machinery than usual. Outside of Mexico, and some work in the Canadian border country, export business is slack. In continental Europe there is very little demand for American machinery at this time, the disposition being inclined to discriminate against it, especially in Great Britain and Germany. South Africa is a good field, but it does not seem to recuperate as rapidly as it should since the Boer war. The great complaint there is the scarcity of labor. Capital is not doing much in the South American republics on account of the almost incessant political uprisings in those countries."

ELECTRIC LIGHT ENGINE WANTED.—The electric light company of Teneriffe, Canary Islands, is desirous of purchasing an American electric light engine of at least 500 hp, as with the machinery they now have they find it impossible to meet the large and constantly-increasing demand for electric light. The engine required must be of the latest pattern, of first-class material, and up-to-date in all respects. Price should be quoted c.i.f. Teneriffe. The following firms issue through bills of lading at Teneriffe: Elder, Dempster & Co., Produce Exchange, New York, and J. M. Ceballos & Co., Wall Street, New York. Quotations and all communications should be addressed to Senor Don Nicolas Marti, presidente Compania Electrica e Industrial, Teneriffe. The above information is from Mr. Sol. Berliner, United States Consul at Teneriffe, Canary Islands, South Atlantic.

SOME BUFFALO FORGE COMPANY ORDERS.—The Buffalo Forge Company reports through its New York offices in the Taylor Building that business in their lines is picking up considerably and that several interesting engines are on hand. The De Witt Wire Cloth Company, De Witt, N. J., is extending its factory and has ordered a horizontal center-crank Buffalo engine of 40-hp capacity for direct connection to a 25-kw Crocker-Wheeler generator. The Newberger Electric Company, of Brooklyn, has ordered a 100-hp horizontal center-crank Buffalo engine for direct connection to a 60-kw Elwell-Parker motor. This outfit is intended for lighting purposes. The Mackay Engineering Company, Singer Building, New York, has requisitioned for a 25-hp vertical engine for direct connection to a 15-kw Akron generator for lighting the Mutual Chemical Company's plant.

FOREIGN TRADE FIGURES.—The month of December shows up well with imports of $77,750,284 and exports of $174,734,368, giving an excess of exports of $96,984,084, the largest excess for any month last year. The total exports excess for the year was $489,122,029, which has only been exceeded in three years since 1892, while the total of exports, $1,484,854,694, is the largest for any year in that long period, and the total import and export trade is also nearly $150,000,000 more than the previous largest year, 1901, being not less than the magnificent figure of $2,480,587,359. This does not look very much like adversity, and there is in it no justification for the shallow pessimism of last year. Moreover, against the highest exports of the year in December, the imports for the same month were the lowest, which does not look like extravagant indulgence in foreign luxuries.

EQUIPMENT FOR NEW LEHIGH VALLEY RAILROAD SHOPS.—Contracts have been let for the equipment of the locomotive shops now under construction at Sayre, Pa., by the Lehigh Valley Railroad Company. The capacity of the power plant will be 8,000 hp. The Westinghouse Electric & Manufacturing Company secured the contract for the generating equipment. McIntosh, Seymour & Co. will build the engines. Wickes Brothers, Saginaw, Mich., have taken the contract for the boilers. The crane equipment will be installed by the Shaw Electric Crane Company, of Muskegon, Mich. There will be twelve cranes. The contract for the ventilating equipment has been let to the Buffalo Forge Company. Ten 10-ft. fans will be installed in the main locomotive shops, each fan driven by 20-hp motors, which have yet to be ordered.

HOLTZER-CABOT PRESS MOTORS.—The American Type Founders Company, of Jersey City, has awarded a contract to the Holtzer-Cabot Electric Company, New York offices 43 Liberty Street, for a number of special designed motors which are to be used for driving the company's catalogue printing presses. Thirteen motors have already been ordered. They will have varying speeds and will be of from ¼ hp to 5 hp capacity. The motors will be fitted with either Carpenter or Cutler-Hammer control. They will be placed under the step of the printing presses. The presses will be built by the Whitlock Company, Derby, Conn. Motors will also drive the servers and cutters.

THE INTERNATIONAL TELEPHONE MANUFACTURING COMPANY, of Chicago, reports a steady demand for its various types of switchboards and telephones, its new type mechanical self-restoring drop board meeting with special favor. Among recent shipments might be mentioned the following: Nappanee, Ind., 300 capacity; Bevier, Mo., a 100-capacity addition to the first section installed within the past thirty days; Bunker Hill, Mo., 100-capacity; South Wayne, Wis., 100-capacity; Gratiot, Wis., 100-capacity; Chatham, Ill., 150-capacity; Divernon, Ill., 150-capacity; Winslow, Ill., 100-capacity. A number of the above orders included complete telephone equipment as well.

BROOKLYN HARDWARE FACTORY.—Percival Robert Moses, 35 Nassau Street, New York, has let contracts for the equipment of the large hardware factory which is being built at Kent Avenue and South Eighth Street, Brooklyn, for Charles R. Ring. The power equipment will have a capacity of 150 hp. The engine, a belted one, will be of Fitchburg build. The boilers, two units, have been ordered from the Bigelow Company, 15 Cortlandt Street, New York. The generator will be of C. & C. make. Its capacity will be 65 kw. A combination passenger and freight elevator will be put in by the A. B. See Elevator Company. Several motors have yet to be ordered.

THE PROMETHEUS ELECTRIC COMPANY, 39 Cortlandt Street, New York, manufacturers of electric heating and cooking apparatus, elected the following officers at its annual meeting: President, David T. Davis; vice-president, Dr. S. S. Wheeler; treasurer, William B. Symmes, Jr.; secretary, Max Loewenthal. The above gentlemen, in conjunction with Mr. Max Osterberg and Mr. William Ballin, constitute the board of directors. The outlook for the sale of the apparatus is reported as excellent, and the sales during the past year have been very encouraging.

TRAIN LIGHTING.—At a meeting of the board of directors of the Consolidated Railway Electric Lighting & Equipment Company, held January 13, Col. John T. Dickinson, heretofore general agent, was elected second vice-president in charge of negotiations with railway companies for the use of the Consolidated "Axle Light" system of electric car lighting. The company's general offices were recently moved from 100 Broadway to the Hanover Bank Building, corner Pine and Nassau Streets, New York City.

THE WESTERN ELECTRIC COMPANY reports having received orders for 250 fire alarm boxes and complete central station equipment for the World's Fair at St. Louis. The apparatus will be similar to that used in the city of Chicago. As a result of the recent fire in the latter city, all the theatres and many of the large business houses are being supplied with Western Electric fire alarm boxes, which will be connected direct with the city system.

EQUIPMENT FOR ARGENTINA FORTIFICATIONS.—The government of the Argentine Republic is to purchase considerable electrical equipment for installation in the fortification works of the Puerto Militar. About $25,000 gold will be expended. The equipments will include machinery for the manipulation of disappearing guns, ammunition hoists, deck winches, portable stationary blowers, etc.

3,000 HP MORE FOR SAO PAULO COMPANY.—The additional equipment to be installed in the Rio Tiete hydraulic plant operated by the Sao Paulo Tramway, Light & Power Company, of Sao Paulo, Brazil, will be of 3,000-hp capacity. The existing plant is of 7,000 hp. The contracts for the new installation will be let through the New York offices of the concern, 29 Broadway, early next month.

STEEL TOWERS FOR MEXICAN TRANSMISSION LINES.—The Mexican Light & Power Company, New York offices 29 Broadway, is in the market for about 2,000 steel towers of special design which are to be used for carrying the transmission lines which are to run between the Necaxa plant of the company to Mexico City, and to El Oro mining district, a total distance of about 150 miles.

THE HERTNER ELECTRIC COMPANY, of Cleveland, Ohio, has just completed the installation of 30 motors in the large printing establishment of Martin & Lamb, of that city. Every press, cutter, folder and stitcher, as well as all the separate tools used in the binding and electrotyping departments, are operated by individual motors specially designed.

PUMPS FOR WORLD'S FAIR.—The Warren Steam Pump Works, of Warren, Mass., have secured the contract for the pumping equipment to be installed in the 5,000-hp plant which is to operate the Intramural Electric Railway in the St. Louis World's Fair grounds.

THE MANSFIELD ENGINEERING COMPANY, of Mansfield, Ohio, is building three 200-hp engines, which will be used in driving part of the electrical equipment at the St. Louis World's Fair.

BALL ENGINE ORDER.—The Union Ice Company, of Bakersfield, Cal., has recently purchased a 300-hp Ball automatic engine from the Ball Engine Company, Erie, Pa.

THE OSBORN ENGINEERING COMPANY is preparing plans for a large plant to be erected at Clarksburg, W. Va., for the National Carbon Company, of Cleveland.

General News.

THE TELEPHONE.

EVENING SHADE, ARK.—The Sharpe County Telephone Company has been incorporated with a capital stock of $1000. C. J. Wilson is president.

LOS ANGELES, CAL.—The Monrovia Telephone & Telegraph Company has created a bonded indebtedness of $25,000.

LOS ANGELES, CAL.—The Imperial Telephone Company is making an extension of its line from Imperial to Holton.

LOS ANGELES, CAL.—The Home Telephone Company has petitioned the City Trustees of Fullerton to advertise for sale a telephone franchise in that city, promising to begin work at once and spend $4000 in two years.

LOS ANGELES, CAL.—Increase in business has made it necessary for the Sunset Telephone Company to construct a new line from San Diego to Corona, a distance of about 100 miles. The new line has been completed to Pala, 45 miles south of Corona.

LOS ANGELES, CAL.—The rumor to the effect that there is to be a merger of the Home Telephone Company with the Sunset Company is denied. At the present time the Home concern has about 11,000 telephones working and nearly as many contracts yet to fill, according to General Manager Van Liew. Furthermore, there are about twenty-five long-distance toll lines connected through, and, in addition to this, all towns in Southern California of 5000 population and over have been connected-up locally. Mr. Van Liew says that he has not had a solicitor out for almost a year, and that contracts are being signed faster than is possible to meet them.

BOISE, IDAHO.—Articles of incorporation of the Independent Long Distance Telephone Company have been filed here. The capital stock is $250,000 and the principal office of the company is to be in this city. The directors are H. E. Neal, E. H. Beggs and A. J. Swain, of Boise; James McDevitt, R. E. Shaw, Harry L. Fisher, C. J. Sinsel and M. B. Zimmer.

DANVILLE, ILL.—The Vermillion County Telephone Company has increased its capital stock from $150,000 to $400,000.

ADRIAN, ILL.—The Carthage & Coluca Telephone Company has been incorporated with a capital stock of $2500. The directors are William Black, J. L. Haines and others.

JACKSONVILLE, ILL.—Representatives of thirteen independent telephone companies in central and western Illinois met at this place Jan. 5, for the purpose of organizing an independent telephone association and of arranging matters so that it will be clearly understood what part of the gross charge each company is to receive for the transmission of a long-distance message, or of messages other than local. It is expected that during the present year they will establish copper metallic circuits between Hannibal, Springfield, Alton, Louisiana, Jacksonville and other cities of importance in the district embraced by the following counties, which were represented in the meeting: Calhoun, Jersey, Macoupin, Green, Scott, Morgan, Cass, Sangamon, Pike, Adams, Browne, Hancock and Hannibal and several counties in Missouri.

SOUTH BEND, IND.—The Central Union Telephone Company will rebuild its plant during the spring, placing the wires underground.

OAKLANDON, IND.—The Rural Telephone Company, of this place, has been organized with a capital of $300. The directors are Michael Mock, Henry Mock and John W. Apple.

MUNCIE, IND.—The Delaware & Madison Counties Telephone Company reports having had a very successful year. The company is now operating over a large territory and has 3100 telephones in service. The company has expended over $80,000 in extensions during the past year.

DANVILLE, IND.—One hundred and thirty-eight farmer patrons of the Consolidated Telephone Company of this city and community are at outs with the management and threaten to organize a company and establish a system of their own. The company has recently consolidated the exchanges in Danville, Plainfield, New Salem and Pittsboro and put in new metallic service greatly improving and extending the service. The management announced that after Dec. 31, the rate for residence and country telephones would be $1 a month, an increase of 25 cents. The farmer patrons rebelled and held a mass meeting and passed resolutions to the effect that they would retain their telephones at the old price, but in case service was denied them they would establish their own system. However, after investigating the cost of a new plant and realizing its limitation, some of the more conservative farmers are inclined to remain with the company. It is asserted that Bell people are backing the farmers and have looked with favor on this territory for some time. The Bell Company has only a pay station in Danville.

EXLINE, IA.—The Exline Telephone Company has ordered 1300 lbs. of wire to build a new line.

VALLEY JUNCTION, IA.—The Grimes Mutual Telephone Company has been granted a local franchise.

REINBECK, IA.—The Reinbeck Mutual Telephone Company has been organized to establish a local mutual exchange.

BUFFALO CENTER, IA.—Another rural telephone line will be built south and east of Buffalo Center by the Great Northern Telephone Company.

JEFFERSON, IA.—The Citizens' Mutual Telephone Company, of Jefferson, has been incorporated. Capital stock, $9990. Incorporators: J. E. Shaw and several others.

VALLEY JUNCTION, IA.—The Valley Junction & Orilla Telephone Company has been organized and will build a line in the spring. F. L. Bailey, of Bloomfield township, is secretary.

DETROIT, KAN.—A farmers' mutual telephone company is being organized by farmers south of Detroit.

MONTGOMERY, MASS.—The New England Telephone & Telegraph Company will build a line from Russell to Montgomery.

ESCANABA, MICH.—The Finch Telephone Company will extend its line to Menominee.

HILLSDALE, MICH.—Extensive improvements to cost in the neighborhood of $8000, are about to be made by the Bell Telephone Company in its Hillsdale plant. The cables are to be extended, the switchboard and operating room enlarged and provision made to accommodate 200 additional subscribers.

PILLAGER, MINN.—E. P. Bacon proposes to establish a telephone exchange in this place.

DASSELL, MINN.—A telephone line is to be constructed to Lake Jennie. Work will be started in the early spring.

COMFREY, MINN.—The North Star Telephone Company contemplates building a line from Comfrey to Springfield.

BLACKDUCK, MINN.—The Blackduck Electric & Telephone Company will be incorporated with $25,000 to $50,000 capital stock.

ST. PAUL, MINN.—The Nicollet County Telephone & Telegraph Company has increased its capital stock from $20,000 to $50,000.

COMSTOCK, MINN.—The Neightborhood State Telephone Company has been incorporated with a capital stock of $25,000. The directors are H. H. Harvey, Sam Gilbert and others.

ABBOTTSFORD, MISS.—The Abbottsford Electric Light & Telephone Company, Abbottsford, Clarke County, has been incorporated; capital stock $25,000. A. J. Young, E. C. Schilling and G. H. Schilling are the incorporators.

SEDALIA, MO.—The Missouri and Kansas Telephone linemen here struck Jan. 2, because their wages had not been increased from $2.25 to $2.50 a day, with one and one-half pay for overtime and double pay for Sundays. The men went to work on the promise that the matter would be considered upon the return of President Burt from Boston, but nothing having been done, they struck again Jan. 6.

BASSETT, NEB.—The Bassett-Springview Telephone Company has increased its capital to $25,000.

VINELAND, N. J.—The United Telephone & Telegraph Company, of Vineland, has been incorporated with a capital stock of $25,000, by Joseph H. Dowler, Jr., Walter D. Wilson, Wm. E. Wilson, J. Homer Lewis and Henry Taylor.

PLAINFIELD, N. J.—The public services committee of the Common Council has recommended that the application for a franchise by the Central New Jersey Telephone Company be refused. In the committee's opinion the time is not ripe for the granting of another license.

SENECA FALLS, N. Y.—The Home Telephone Company is about to extend its line from Waterloo to Geneva.

WHITESBORO, N. Y.—The Central New York Telephone & Telegraph Company and the Utica Home Telephone Company have made application for franchises in the village.

NORTH WALCOTT, N. Y.—The North Walcott Telephone Company has been incorporated with a capital stock of $5500, by D. J. Kyle, N. F. Fields, and George W. Van Note.

PLATTSBURGH, N. Y.—The Beekmantown Telephone Company, of Plattsburgh, N. Y., has been incorporated; capital, $1000. Incorporators: Chellis Brothers, Addison Ladd, Nathan R. Mason, all of Plattsburgh, N. Y.

RICHFIELD SPRINGS, N. Y.—The Winfield Home Telephone Company, Richfield Springs, has been incorporated; capital, $5000. Incorporators: Frederick C. Ward, Cooperstown; Willard Bullion, George Cany, Richfield Springs.

JAMAICA, L. I., N. Y.—The New York & Long Island Telephone Company is strongly competing with the New York & New Jersey Telephone Company in this section. The new company is offering all sorts of inducements to subscribers. The New York & New Jersey Company has as yet made no effort to meet the competition.

QUAKER CITY, OHIO.—The Yoker Valley Telephone Company has been incorporated with a capital stock of $550. Directors: W. W. James, N. P. Hartley and others.

CHATTANOOGA, TENN.—After a long fight over the question of a charter for an independent telephone company in Chattanooga, the matter has been settled by the signing of a contract by the East Tennessee and Hamilton Telephone Companies, fixing the charges in the city and suburbs by specifying the rates to be charged within prescribed limits.

MIDLAND, TEX.—The Automatic Telephone Company has been incorporated with a capital stock of $10,000. Directors: E. H. Estes, J. T. Blair and others.

BEAUMONT, TEX.—The Southwestern Telegraph & Telephone Company will erect an office and exchange building here. J. E. Farnsworth, general manager, Dallas, Texas, can give information.

SMITHVILLE, TEX.—The Smithville Telephone Company, of this place, has purchased the telephone line of the Smithville & Red Rock Telephone Company and will extend it to Lockhart.

PETERSBURG, VA.—The Petersburg Telephone Company is extending its line from DeWitt to McKenney Station in Dinwiddie County.

PORT ROYAL, VA.—The Royal Telephone Company, of this place, has been chartered with a capital stock of $3000 to $5000. Mr. George W. Forsyth is secretary and treasurer.

CHEHALIS, WASH.—A telephone company is projected to build a line to Aberdeen.

CENTRALIA, WASH.—The Sunset Telephone Company will build a line from this city to Elma, 30 miles.

EVERETT, WASH.—The Skagit Farmers' Mutual Telephone Company will ask for a franchise for an independent telephone system.

READSTOWN, WIS.—The Readstown Telephone Company of the village of Readstown, Vernon County; capital $5000, has been incorporated by F. M. Groves, G. W. Heinka, C. A. Reeve and G. A. Ewers.

Electric Light and Power.

TEMPE, ARIZ.—The Tempe Canal Company will probably construct a power plant to cost $170,000. G. Jones, J. Woolf and Carl Hayden, all of Tempe, are among the stockholders.

ALHAMBRA, CAL.—Bids are wanted Feb. 9 for a franchise for furnishing electricity for light, heat and power. A. A. Clapp, Sr., is City Clerk.

LOS ANGELES, CAL.—A company has been organized at Downey to build an electric light plant. The incorporators are Dr. Q. J. Rowley, A. L. Ball, T. R. Crawford, Joseph Smith and S. S. Skidmore.

LOS ANGELES, CAL.—John B. Miller, president of the Edison Electric Company, speaking of the company's plans, says: "The first power line in the vicinity of Santa Barbara will be a branch line from the 60,000-volt transmission line, to connect with the 28,000-hp plant we are building at the mouth of Kern River, but this plant will not be completed for about 18 months. We expect, however, to complete a 1000-hp plant on Lytle Creek some time in February or March, and another plant of 2000-hp capacity on the Santa Ana River, immediately below our 4000-hp plant on that river, some time next summer. Both of these plants will be connected with our main transmission line running from Santa Ana River and Mill Creek, back of Redlands, to Los Angeles, and will represent an expenditure of about $350,000."

SOUTH GLASTONBURY, CONN.—Engineers Daboll & Crandall, of New London, are preparing an estimate of the available power and cost of development of Roaring Brook.

SANDERSVILLE, GA.—Bids are wanted Jan. 27 for constructing water works and an electric light plant.

ALBANY, GA.—The city of Albany has agreed to take 300 electrical horsepower for lighting the city and supplying power at the water plant, from the Florida capitalists who have in hand the proposed development of Big Shoals on Muckafoonee creek. It is proposed to develop from 15,000 to 25,000 horsepower.

ATLANTA, GA.—Park Woodward, general manager Water Works Department, in his annual message recommends an electric light plant for No. 2 pumping station, the filter house and the old and new reservoirs, at a cost of $5000.

HAILEY, IDA.—R. J. Allen, of this city, is promoter of an enterprise to build a power plant here at a cost of about $50,000.

MOLINE, ILL.—The People's Power Company will purchase two watertube boilers and one 250-hp engine.

PEORIA, ILL.—The Peoria Gas Light & Coke Company has been bought by the Peoria Gas & Electric Company. The capital stock has been increased from $2,000,000 to $2,500,000.

TAMMS, ILL.—The Illinois Milling & Elevating Company has been incorporated, with a capital of $50,000. It will furnish electric light and power. The incorporators are Oscar T. Tamm, Joseph Mayer, Jr., David S. Lansden.

MONTPELIER, IND.—The city is considering the question of constructing an electric light plant.

NORWAY, IND.—A. A. McKain, of this place, and others, of Indianapolis, have purchased the power dam in Tippecanoe River, and will at once establish an electric power plant.

SOUTH BEND, IND.—The South Bend Electric Company is preparing to place its wires underground, and arranging for the new lighting system, which will require about 450 enclosed arc lights. F. A. Bryan is general manager.

VINCENNES, IND.—The City Council has granted P. K. Tyng an extended franchise of 25 years for his electric light plant and service. Mr. Tyng is to furnish free lights to the city hall, the city to pay for all fixtures and breakages after once placed.

MONTICELLO, IND.—A. A. McKam and others, of Indianapolis, have purchased the water power dams at Norway and Tioga, on the Tippecanoe River near here and will at once improve them for the purpose of erecting electrical power plants. The promoters propose furnishing electricity to the surrounding towns and cities.

CRESTON, IA.—M. E. Springer, of Des Moines, is interested in the construction of an electric light and gas plant for Creston.

BAXTER SPRINGS, KAN.—It is stated that the deal for the transfer of water rights at Baxter Springs from the city to W. G. Sergeant, of Joplin, Mo., has been closed. He proposes commencing work in the spring. The power house will be constructed at Lowell.

PORTLAND, ME.—The North Shore Power Company has been incorporated to supply electricity for light, heat and power; capital, $500,000. C. C. Le Grow and E. E. Stone, both of Portland, and H. E. Stevens, Boston, Mass., are among the directors.

WARE, MASS.—The Ware Electric Company has petitioned the State Board of Gas and Electric Light Commissioners at Boston for authority to issue additional capital to the amount of $10,000 for the purpose of extending the plant.

HOLYOKE, MASS.—According to the annual report of the Gas and Electric Department of Holyoke, the equipment of the electric light station which was transferred to the city less than one year ago was at that time obsolete and overloaded. The poles were decayed and the wire insulation badly impaired, and all overloaded. It has been decided to discard all of the present electrical machinery and substitute for the small units two large ones that will develop electrically and economically all of the power furnished by the water wheels. It is also planned to change the entire street lighting service to enclosed arcs and add 236 lights to the 263 at present in use, making a total of 499 street lamps.

BUFFALO, N. Y.—The electrical workers of this city are on a strike because the contractors decided to keep "open shop."

SCHENECTADY, N. Y.—The Schenectady Railway Company secured the contract for lighting the city for three years at 22½ cts. per lamp per night.

CAMDEN, N. Y.—The citizens voted Dec. 29 to issue $40,000 bonds for the establishment of a municipal electric light plant. H. B. Sweet, of Utica, is engineer. H. G. DuBois is president of the Council.

ONEIDA, N. Y.—It is stated that arrangements have been made by the Madison County Gas & Electric Company to acquire the Lime Kiln Falls electric water power plant. Mr. DeWitt C. Haddock will complete the Falls plant and have it ready by July 1 next. The plant will have a capacity of 1500 horsepower and will cost about $130,000.

WINSTON, N. C.—W. T. Brown and others have been appointed a committee to investigate the feasibility of an electric lighting plant in this city.

ATTICA, OHIO.—An election has resulted in favor of issuing $6250 in bonds for the purpose of building a municipal lighting plant.

TOLEDO, OHIO.—The Hocking Valley Railway Company will spend $50,000 in installing a power plant and equipping all its machinery on its coal and ore docks here with electricity in place of steam.

XENIA, OHIO.—Charles Darlington, M. D. Stewart and others are planning to organize a co-operate electric light company. The capital stock will be $30,000. The company will erect a lighting plant and furnish current for commercial and private use.

KENTON, OHIO.—The Kenton Ice Company will erect an artificial ice plant and install considerable electrical equipment. The York Manufacturing Company, of York, Pa., is supplying plans for the plant. W. P. Bowman is manager of the Kenton Company.

ELYRIA, OHIO.—The Ely Realty Company is erecting an addition to its power plant and will install a 300-hp gas engine direct-connected to a Westinghouse alternating current generator. A rotary converter will be installed for supplying direct current to a portion of the system.

MASSILLON, OHIO.—At the recent meeting of stock holders of the Massillon Light, Heat & Power Company, directors were elected and they, in turn, elected officers as follows: President and treasurer, Warren E. Russell; vice-president, Joseph K. Russell; secretary, Maurice R. Bissell.

SHERIDAN, ORE.—The Yamhill Milling Company, of Sheridan, is considering the installation of an electric light plant for its mill, and also for lighting the town.

ROSEBURG, ORE.—The plants of the Douglas Electric and Water Company, of this city, and the Roseburg Water & Light Company, of Winchester, have been purchased by the Oregon Boom & Timber Company, the consideration being $125,000 for the Winchester plant and $50,000 for the Roseburg holdings.

BRADDOCK, PA.—An ordinance has been submitted to Council providing for an issue of $20,000 bonds for a municipal electric light plant.

GETTYSBURG, PA.—The Council has authorized the Light Commission to procure an estimate of cost of constructing and operating a municipal electric light plant.

HARRISBURG, PA.—According to a report made by Prof. Jackson, of the State College, the Harrisburg Light, Heat & Power Company is supplying not more than one-half the light required by the contract with the city. The investigation was made at the instance of Mayor McCormick.

SARATOGA, TEX.—The Sour Lake Electric Light & Power Company, of Sour Lake, will install an electric light and power plant at this place.

SALT LAKE CITY, UTAH.—A deal which creates an electrical monopoly in the state was consummated in the merger of the Utah Light & Power Company and Consolidated Railway & Power Company under the name of the Utah Light & Railway Company. The new corporation is capitalized for $10,000,000. Joseph F. Smith was selected president of the company and the former manager of the Utah Light & Power Company, R. S. Campbell, will be secretary and general manager. Extensive improvements will be commenced at once, and the directors have in view the outlay of about $1,000,000 in the next few years in repairs and improvements. Of the total capitalization $4,000,000 will be held for sale for the improvement of the plant and system.

WISE, VA.—The Cumberland Light & Transportation Company has been organized at Wise, by E. M. Fulton, H. M. Smyth, G. A. Esser and others to build an electric railway from Wise, connecting the mining towns of Norton, Glamorgan, Dorchester, Coeburn, Big Stone Gap and Stonega. Bids for construction will be received till Jan. 15. Address, E. M. Fulton, of Wise.

EVERETT, WASH.—It is reported that J. T. McChesney will expend about $500,000 in developing the falls near Wallace on May Creek.

SHELTON, WASH.—W. H. Kneeland has purchased the Shelton electric light plant and proposed increasing it and improving the service.

MOUNDSVILLE, W. VA.—The Council has granted a franchise to the Moundsville Electrical Company.

SHAWANO, WIS.—The citizens have voted to issue bonds for enlarging the electric light plant.

ANTIGO, WIS.—A charter has been granted to the Antigo Light, Heat & Power Company, of Antigo; capital, $50,000. Incorporators: W. L. Elliott, C. T. Mortensen and F. C. Duchac.

OTTAWA, ONT.—The ratepayers of the city of Ottawa have voted by a large majority to adopt a by-law providing $50,000 for the establishment and operation by the municipality of an electric lighting plant for street lighting purposes.

MONTREAL, QUE.—Engineer J. Phelps, of Baltimore, Md., has submitted his report to Council on the cost to the city of a modern conduit system. There is an estimate on four classes of conduits to be known as Classes A, B, C and D. According to Class C, which he recommends for Montreal, the cost per duct foot is 37.24 cts.; the main conduit to cost $1,005,750, and the distributing system $199,100. According to Class A, the cost per duct foot is 45.9 cts.; Class B, 43.34 cts., and Class D, 34.68 cts.

THE ELECTRIC RAILWAY.

OPELIKA, ALA.—Rush Taylor has secured a franchise to build an electric railway from Opelika to Auburn. The road will be known as the Opelika Electric Street and Interurabn Electric Railway.

SAN FRANCISCO, CAL.—The shareholders of the Petaluma & Santa Rosa (Electric) Railway will meet in San Francisco, on Feb. 9, to authorize a mortgage to the Mercantile Trust Company, of San Francisco, to secure an issue of $1,000,000 of 5 per cent 20-year gold bonds, to be dated March 1, 1903, and to be subject to call on six months' notice at 110. Of the bonds, $500,000 will be reserved for extensions. E. H. Rollins & Sons, the bankers, have arranged to finance the enterprise. The company was incorporated on June 20, 1903, with $1,000,000 authorized capital stock, to build 32 miles of electric railway between Petaluma, Sebastapool, Santa Rosa and Forestville. There will be steamer connection between San Francisco and Petaluma. The officers and directors are John A. McNear, president; W. F. Kelly, vice-president; Burke Corbet, treasurer; Thomas Archer, secretary; Francis Cutting, of the Cutting Company; W. F. Kelly, of the Oakland Transit Company; Thomas Archer, of the E. H. Rollins & Sons, of Boston; John A. McNear, Burke Corbet, W. H. Pope and F. A. Brush, of the Santa Rosa National Bank, directors.

CHICAGO, ILL.—The Metropolitan West Side Elevated Railroad Company has made application to list $7,500,000 common stock on the New York Stock Exchange.

TAYLORVILLE, ILL.—David M. Sharp, of Taylorville, has applied to the Secretary of State for articles of incorporation for an interurban railway system in this county. The company will be capitalized at $205,000.

CHICAGO, ILL.—The Springfield & Peoria Railway has been incorporated with a capital of $50,000. Incorporators and first board of directors: Francis S. Peabody, John J. Hart, Arthur W. Underwood, Frederick W. Upham, all of Chicago, Ill.

PEORIA, ILL.—The Peoria & Rock Island Traction Company has been incorporated; capital $100,000. Incorporators and first board of directors: W. B. McKinley, Charles Zilly, B. R. Stephens, B. E. Cartwright and J. E. Barry, all of Champaign, Ill.

MENDOTA, ILL.—The Northern Illinois Traction Company has been incorporated with a capital of $25,000. The incorporators and first board of directors are Hal B. Allen, Erie, Ill.; W. A. Burkley, Mendota, Ill.; George W. Hamilton, Means A. Booth and W. E. Booth, New Bedford, Ill.

NATICK, MASS.—The Natick & Needham Street Railway has gone into the hands of N. Summer Myrick as receiver on the petition of its stockholders. The petition for the appointment of a receiver was the outcome of the refusal of the receiver appointed for the South Middlesex Street Railway, to which the Natick & Needham Street Railway was leased, to operate the latter line. It is said that the Natick & Needham will now surrender its charter; that the road will be dug up, and that the rails and rolling stock will be disposed of at the best price they will bring.

BROOKLYN, N. Y.—The Appellate Division of the Supreme Court, in Brooklyn, has handed down a decision sustaining the city's ordinance requiring street railroad companies to carry passengers from any part of the railroad to their destination at any other part of the same railroad without a change of cars.

GLOVERSVILLE, N. Y.—The Fonda, Johnstown & Gloversville Railroad Company has purchased the property of the Adirondacks Lakes Traction Company, consisting of the electric railway leading from Gloversville to Mountain Lake, and all the hotels, pavilions and other property at the lake. The road will be run independently of the Fonda, Johnstown & Gloversville system. The following officers have been elected: John Shanahan, president; Lyman K. Brown, vice-president; E. H. Steckel, secretary.

NEW YORK, N. Y.—Supreme Court Justice Fitzgerald, of White Plains, has granted an order allowing the Interurban Street Railway Company to assume the new name of "New York City Railway Company" on and after Feb. 10 next. The petition of the company asking for the change says: "At the present time there are several corporations operating in the same district, which results in confusion tending to prejudice its interests, and the name it desires to adopt will better indicate the nature and extent of its system, which comprises practically the entire surface street railway system in New York City."

CHARLOTTE, N. C.—The Goldsboro and Seven Springs Securities Company is a new North Carolina concern which, among other rights, has the privilege of building street car and trolley lines, hotels, roads, etc., capital $150,000.

YORK, PA.—The York County Traction Company, which has been negotiating for the purchase of the Hanover & McSherrystown Street Railway Company and the Hanover Light & Power Company, has consummated the deal, and the two companies will now be merged in one and form one county system covering almost every important point in York County. The consideration was $100,000. The officers of the Hanover & McSherrytown Street Railway Company resigned their positions Dec. 31, and the new officers were elected to take their place as follows: Captain W. H. Lanius, of York, president; Ellis S. Lewis, of York, treasurer; George S. Billmeyer, John W. Steacy, of York; William A. Himes, of New Oxford, Harry N. Gitt, Charles Ehrhart and Thomas J. O'Neall, of Hanover, directors.

WAUWATOSA, WIS.—Mayor E. D. Hoyt and the Common Council of Wauwatosa have filed an answer to the petition of the residents for a writ of mandamus to compel the city authorities to submit the question of railway franchise ordinance to a vote of the people, in which they state that the latter had no right to vote upon the subject. They assert that the ordinance is not a new one and that it seeks to extend existing railway lines and is simply an extension or an amendment of the present ordinance, and therefore does not come within the law enacted by the legislature last spring.

NEW INDUSTRIAL COMPANIES.

THE AMERICAN CAR TELEPHONE COMPANY has been incorporated at Grand Rapids, Mich., with a capital stock of $2,500,000.

THE VACUO-STATIC CARBON COMPANY, of Rochester, N. Y., has been incorporated with a capital stock of $60,000. The directors are P. A. Clum, C. M. Lane and F. J. Cross, Rochester.

THE ECONOMIC ELECTRIC COMPANY, of New York, has been incorporated; capital, $200,000. Directors: L. L. Roberts and Edmund Tweedy, of New York, and William Newcomb, of Tenafly, N. J.

THE ELECTRIC DEVELOPMENT & SECURITIES COMPANY, with a capital stock of $100,000, has been incorporated in New York City. The directors are W. C. Goodale, J. M. O'Laughlin and M. R. O'Laughlin, of New York City.

THE CUMBERLAND ENGINEERING COMPANY has been incorporated at Cleveland, Ohio, with $25,000 capital stock, by W. H. Pelton, A. E. Thompson, E. Shoemaker, E. L. Dulz and N. B. Daerr. The company will do a general contracting business.

THE PRISMATIC ELECTRIC MFG. COMPANY, of New York City, has been incorporated to manufacture prismatic and electrical novelties. The capital stock is $200,000, and the incorporators and directors for the first year are M. E. Wooster, C. E. Bleyer and L. Wallach, of New York City.

THE MOLINE INCANDESCENT LAMP COMPANY has been incorporated at Moline, Ill., by Albert H. Kreitler, C. F. Gantz and E. E. Morgan. The purpose of the company is to manufacture incandescent lamps and other electrical apparatus. The capital stock is $30,000, and the first board of directors is composed of the following-named gentlemen: C. H. Deere, E. E. Morgan, H. W. Cooper, C. P. Skinner, C. R. Wood, Edward Coryn and A. H. Kreitler.

OBITUARY.

MR. W. W. SKILES.—We regret to learn the death on Jan. 9, of Mr. W. W. Skiles, the president of the Shelby Electric Company, of Shelby, Ohio. The funeral took place on Jan. 13.

MR. A. G. NICHOLS.—Mr. Amos G. Nichols, president of the New York Safety Steam Power Company and president of the Langworthy Machine Company, died at Hope Valley, R. I., on Wednesday, Jan. 13, after a short illness. Funeral services were held at Hope Valley on Jan. 16.

MR. A. G. GARRISON.—We learn with deep regret, just at the moment of going to press, the news of the death of Mr. W. O. Garrison, president of the Columbia Incandescent Lamp Company, of St. Louis. This young and talented man has been ill for some time, but this news will come as a severe blow to a wide circle of friends and admirers all over the country.

PERSONAL.

W. T. GENTRY.

MR. W. T. GENTRY.—Vice-president and general manager W. T. Gentry, of the Southern Bell Telephone and Telegraph Company, was given a dinner at the Capital City Club, Atlanta, Ga., on Thursday, January 14, by the officials of the company in commemoration of the twenty-fifth anniversary of his continuous service. Among other prominent officials invited or attending were Mr. Edward J. Hall, president of the company, and vice-president of the American Telephone and Telegraph Company, and Mr. Charles H. Wilson, general superintendent of the latter company and formerly general manager of the Southern Bell Company. The territory under the management of Mr. Gentry embraces seven southern states and the company operates upwards of 40,000 telephones. Mr. Gentry is a man of much energy—democratic in his ways and personally known to almost every employe—and to thousands of business men and officials throughout the seven southern states within the jurisdiction of his company. He is gentle of speech and beneficent of mind—wise to resolve and patient to perform—of the mildest manner and gentlest heart. Mr. Gentry entered business life as a telegraph operator for the Southern Atlantic Telegraph Company in 1870, at Charlottesville, Va., serving the company later at Lynchburg and Richmond, Va., finally receiving the appointment of circuit manager with headquarters at Gormondsville, Va. The Southern Atlantic Company being absorbed in 1876 by the Western Union Telegraph Company, Mr. Gentry was transferred to Wilmington, N. C., at which place in 1879 he built the first telephone exchange, using the Edison patents and apparatus. After three years' service, he was again transferred to the management of the Western Union office at Alexandria, Va., constructing at that place a telephone exchange in the interest of the Southern Bell Telephone and Telegraph Company and managing it in conjunction with the Western Union office until the latter part of 1883 when he accepted the appointment of manager of the same company's telephone exchange at Atlanta, Ga., and later was appointed assistant superintendent, which position he held until 1896, when he was again promoted to the position of general superintendent of construction for the entire territory of the company, which included seven southern states. In 1901 Mr. Gentry became general manager, and in 1903 was elected vice-president and general manager, which position he now holds with headquarters at Atlanta.

GEORGE W. DAVENPORT.

MR. GEORGE W. DAVENPORT, whose portrait is presented herewith, has, as noted in these columns, been elected recently third vice-president of the Niagara Falls Power Company, that office having been created quite recently. The appointment took effect on Jan. 1 and Mr. Davenport is now in residence at Niagara Falls, where he will perform the duties assigned to him by the second vice-president, whom he will assist, Mr. Rankine, finding that the constantly increasing business of the Niagara Falls Power Company and its allied concerns demands attention from a man of Mr. Davenport's scope of experience, energy and ability. Mr. Davenport, after a course in the Massachusetts Institute of Technology, and factory experience with the Thomson-Houston Electric Company at Lynn, Mass., became general manager of the Thomson-Houston International Company, and for eight years was connected with that company and the General Electric Company. When the General Electric Company, in 1893, turned over to a board of trustees, known as the trustees of Street Railway and Illuminating Properties, over ten millions of securities of various electric lighting and railway companies situated in different parts of the United States, Mr. Davenport became assistant to the trustees, and had a varied experience in the examination, operation, and management of many of the 136 properties in which the trustees were interested. He has recently been second vice-president of the Planters' Compress Company, whose head office is in Boston. As an associate of Mr. C. A. Coffin in the old Thomson-Houston days, and latterly as an expert and manager in connection with electric light and power properties, Mr. Davenport has made a great success, being also one of the most widely known men in the central station field. He is a man of marked personality, charming manners and is not only conversant with affairs but a deeply read student, one of his hobbies being the collection of old books and early electrical literature. His new appointment gives much pleasure to a host of friends who have watched his career with interest.

DR. LEE DE FOREST has returned from England where his wireless telegraph system has been attracting considerable attention.

MADAME CURIE, of radium fame, has been awarded $12,000 as part of the Osiris prize by the Institute of France, and M. Branly has been awarded the remaining $8000.

MR. W. T. JACKSON, western representative, was recently in Chicago on an extended trip throughout the west, in the interests of G. M. Gest, the contractor of Cincinnati, New York and Boston.

MR. ERNEST H. DAVIS, secretary of the National Electric Light Association, has advised members that the transactions for last year will soon be out, but has been delayed by the unusual bulk of its contents.

MR. GUY E. PAINE, formerly superintendent of the Postal Telegraph-Cable Company, at St. Louis, has been appointed general superintendent of the southern division of the same system, with headquarters at Atlanta, Ga.

MR. H. F. PARSHALL, the well-known consulting electrical engineer who has so long been domiciled in England and engaged there on important electric railway work is visiting this country for a brief stay of two or three weeks.

MR. F. M. ASHLEY has become associated with Philip K. Stern and will conduct business under the firm name of Ashley & Stern at 130 Fulton Street, New York, as consulting electrical and mechanical engineers and solicitors of patents.

MR. GUSTAVO LOBO, an electrical and mechanical engineer, well known at one time in this city, announces his wedding at the Church of Our Lady of Lourdes, City of Mexico, to Miss Maria de los Dolores, daughter of Mr. and Mrs. Agustin Pradillo, of that city.

MR. AUGUSTUS D. WALLER, a well-known English educator and member of the Senate of London University, is about to publish in this country through E. P. Dutton & Company a small volume entitled "Eight Lectures on the Signs of Life from Their Electrical Aspect."

MR. B. F. ALLEN, chief engineer of the Harrisburg, Pa., Foundry Company Machine Works, was in town for a few days this week. He reports that business is very promising and that the works have contracts in hand which will keep them busy night and day for at least four months.

MR. G. H. PIERCE.—The International Telephone Mfg. Company, of Chicago, has secured the services of Mr. Geo. H. Pierce, who formerly represented the Stromberg-Carlson Company in New York and New Jersey. Mr. Pierce will cover the state of Iowa with headquarters at Des Moines.

MESSRS. RUEBEL & SCHULTE, engineers of the Anheuser-Busch Brewing Company, of St. Louis, Mo., are now in New York for the purpose of securing estimates for equipment to be installed in an extension to the company's plant. It is proposed to install 800-hp of additional electrical machinery.

MR. ANATOL FOMILIANT, student at the Imperial Technical College of Moscow, Russia, is on a visit to this country to make arrangements for an excursion to the World's Fair of a body of students from the Moscow College. The excursion has been authorized by, and will be under the auspices of, the college authorities.

MR. MAX LOWENTHAL, secretary and engineer of the Prometheus Electric Company, of New York, has started on a trip through the eastern and middle states to establish agencies for the electric heating apparatus of that concern. A number of interesting technical problems await his attention. The company has already established several agencies.

MR. A. FREDERICK COLLINS has recently prepared three contributions for the Encyclopedia Americana of the *Scientific American* on telegraphy, wireless telegraphy and wireless telephony. He has also been a contributor to the International Encyclopedia on wireless telegraphy. Some of his recent "popular" work for the *New York Herald* has been excellent.

MR. FRANK WISNER has been appointed chief electrician of the electrical equipment in the various power houses of the Cleveland Electric Railway Company. He succeeds Mr. George Bacon who has become identified with the Willard Storage Battery Company of Cleveland. Mr. Wisner was formerly chief electrician of the Cleveland City Railway Company.

MR. ANDREW KEISER, superintendent of telegraphs of the Pennsylvania Railroad, and Mr. R. H. Rudd, assistant engineer of signals, are going abroad to study features of transportation work in Europe, including England, France and Germany. Mr. R. E. McCarty, assistant superintendent of the Pittsburg division of the Pan Handle system, is to accompany them.

MR. W. E. L. GAINES, general manager of the National Telephone Company, London, and Mr. Frank Gill, engineer-in-chief of the same company, are making a tour of telephone and electrical plants of this country and Canada. They recently visited the exchange of the Buffalo Telephone Company and then went to Niagara Falls to inspect the power plants there.

MR. J. E. WOODBRIDGE, of the railway engineering department of the General Electric Company at Schenectady has been transferred to the British Thomson-Houston Company, at Rugby, England, where he should now be addressed. Mr. Woodbridge was at one time editor of *The Electrical World* and left its staff a few years ago to devote himself more particularly to direct engineering work.

MR. E. G. LONG, who was for several years associated with the Brush and General Electric companies, and who, during the past five years, has acted as vice-president and general sales agent of the Peckham Mfg. Company, has opened offices at 95 Liberty Street, for the purpose of doing business in electric railway materials. Mr. Long will make a specialty of catering to the export trade and is figuring on some substantial contracts.

MR. SAMUEL INSULL, president Chicago Edison Company, has been in New York City this week, taking among other things an active share in the Edison Medal Association of which he is chairman and which intends to present its fund to the Institute at the annual dinner at the Waldorf on February 11. Mr. Insull is also very much interested in the historical exhibit of the Edison companies to be made at St. Louis this year.

MR. W. J. JOHNSTON has sold to Mr. H. M. Swetland his stock interest in the Johnston Publishing Company, the corporation which owns *The Engineering and Mining Journal*, and has severed his connection with that publication. Mr. Johnston will now devote his entire time and energies to the development of the *Pacific Coast Miner*, which he has owned personally for the past year, but to which heretofore he has only been able to give "absent treatment."

MR. H. M. DEAVITT, analytical and consulting chemist and assayer, with a large practice in Chicago, has taken the management of the Chicago office of the Engineering Company of America, 159 LaSalle St. Mr. Ellis C. Spoker, the expert in cement plants, has also become associated with the Engineering Company of America with headquarters at its Chicago office. Mr. Edward Everett, civil engineer, who has specialized in railroad work, and who made the survey for one of the Hudson River tunnels, has become associated with the company at its New York office, 74 Broadway.

MR. M. G. HUBBARD who has been recently elected secretary and treasurer of C. E. Hewitt & Company, engineers and contractors, Park Row Building, New York, was for 13 years engineer and general superintendent of the McGuire Manufacturing Company, of Chicago. For the last three years he has been engaged in exporting railway supplies at No. 114 Liberty St., New York. While with the McGuire Manufacturing Company he spent considerable time on the road and became well known in electrical railway circles. By experience and training he is well fitted for his new business, and his many friends will wish him every success.

MR. N. S. BRADEN, formerly manager of the Westinghouse Electric & Manufacturing Company's district office at Cleveland, Ohio, has been appointed sales manager of the new Canadian Westinghouse Company, Ltd., and assumed the duties of that office on Jan. 1, 1904. Mr. Braden succeeds the late Mr. Thomas C. Frenyear, who died on Dec. 10. Mr. Frenyear's office was at Toronto, but Mr. Braden will make his headquarters at Hamilton, Ont. Mr. Braden was born at Indianapolis, Ind., thirty-four years ago. He finished his schooling in 1892, and went with the Jenney Electric Motor Company in his native city. He remained with that company until 1899, when he joined the Cleveland district sales office of the Westinghouse Company, as a salesman, where he later became manager.

PROF. S. P. LANGLEY, head of the Smithsonian Institution, was guest of honor at a dinner given by Mr. John Brisben Walker at the Waldorf-Astoria, New York, on January 19. There were many well-known men present. Mr. Walker said that he believed the Langley flying machine would be a commercial possibility within twelve months, and that within twenty-five years it would be the safest means of travel. Santos-Dumont received a rousing welcome. He simply addressed two words to Prof. Langley, these being "Be constant." Edwin Markham, the poet, indulged in a bit of imaginative picturing of the aerial highways of the future. Charles Francis Adams spoke in a similar vein, and went into detail regarding a plan of campaign against neighboring planets. Arthur Brisbane, Gen. Davis, Murat Halstead and others also spoke.

Trade Notes.

THE TRENTON PORCELAIN COMPANY, Trenton, N. J., is manufacturing a high grade of porcelain for all electrical purposes. Its goods have given satisfaction wherever used and the company is increasing its business rapidly. It makes a specialty of all porcelain made for particular uses.

THE HORTON-MASSNICK COMPANY, 11-23 Raynor St., Detroit, Mich., is now putting on the market the "Arkless" fuse formerly manufactured by another concern. This fuse may be placed in any position between terminals any distance apart. This affords a variety of adaptability not usually found.

THE ELECTRICAL POWER STORAGE COMPANY, Limited, 4 Great Winchester Street, London, E. C., England, is distributing its usual annual combination pad, consisting of a desk blotting pad, with a monthly calendar running across the top, and a diary attached to the side. It is a very useful adjunct to any desk. Inside of the diary is an insurance policy covering railroad accidents in the United Kingdom.

THE CENTRAL ELECTRIC COMPANY, Chicago, reports an exceedingly good business on Columbia incandescent lamps for which it is sales agent. Up to this time the Columbia lamp has been manufactured in only the ordinary incandescent and series burning types. The Central Electric Co. is authority for the statement that it will now be able to supply miniature lamps of the Columbia brand which will doubtless meet with a large demand.

THE STUART-HOWLAND COMPANY, of Boston, Mass., is proud of its growth. Starting in a modest way four years ago, it has developed one of the largest supply businesses in New England. In order to impress upon the users of electrical supplies the present size and importance of the concern it has issued a tasteful calendar, with a half-tone illustration on it of its present quarters. The stock which this enterprising company carries of all kinds of supplies makes it a most convenient house to do business with in its section of the country.

THE LUNKENHEIMER COMPANY, Cincinnati, maker of superior brass and iron steam specialties, reports that owing to the unprecedented and growing demand for its specialties, it has again greatly increased its facilities and is now in position to guarantee reasonably prompt shipments. It also reports through its foreign branches an increasing export demand for its specialties and informs us that it will shortly place some new specialties upon the market, which will be contained in a very complete catalogue to be issued in the course of a few months.

FLASH LIGHTS.—Electric portable flash lights are growing more and more popular. The American Endoscopic Company, Providence, R. I., makes a flash and search light that is stated to be up-to-date and complete in every particular. An advantage in the construction of this device is that it can be easily taken apart and examined. On a card recently sent out by the company one of these lamps is shown dissected. The size of the lamp is 1½ by 9 inches and the life of the battery is stated in terms of flashes, being good for 8000 to 10,000 flashes, an equivalent of 7 to 8 hours continuous use. The battery is said to be good for three months' service.

HART & COMPANY, 256 Dearborn St., Chicago, have issued a four-page circular describing their bronze woven-wire gauze brushes, manufactured of the finest bronze woven wire gauze. It is claimed that they need no trimming and very little adjusting and that they will not cut or scratch the commutator. Another production of the concern is their Red Cross commutator compound which lubricates the commutator and prevents cutting. A six-page circular issued by the same people describes their carbon brushes, contains illustrations of six different shapes and styles and gives price on nearly 250 different sizes of brush.

THE TRUMBULL ELECTRIC MFG. COMPANY, Plainville, Conn., has issued a 48-page catalogue bound in an attractive cover which contains illustrations and descriptions of the various knife switches which it makes. In addition to that there are shown illustrations of its rheostats, sockets, cut-outs and the various specialties which it has put on the work recently, including its new flush receptacle taking the Edison base attachment plug. The pendant push button switch on which a patent was allowed in the early part of 1903 is also contained in this catalogue and a sectional view shows the operation very clearly. One push button is used both for opening and closing the circuit.

TAKING CARE OF ORDERS.—At the annual banquet of the Electric Appliance Company, Chicago, on Jan. 9, a series of papers were read by the salesmen and heads of departments dealing with the origin, care and shipment of an order. The taking and shipping of an order would seem to be but a simple matter. Those who listened to this series of papers, however, were impressed with the care and knowledge and thought necessary to properly handle an order to the satisfaction of an up-to-date supply house and of the wide awake customers of to-day. The Electric Appliance Company is to be congratulated upon its admirable organization and on the bright set of men with which it has surrounded itself.

THE CENTRAL STATION ENGINEERING COMPANY has been organized for the purpose of remodeling and placing on a paying basis electric light, street railway, gas and heating properties, which may wish to avail themselves of the experience of engineers who have had broad experience in those lines. They are prepared to investigate properties as to whether improvement is possible, what improvements should be made, and how and where to buy the necessary machinery for such improvements. They are also prepared to furnish plans for complete systems of office book-keeping, both cash and material accounts, so that the conditions of a plant can be ascertained with ease at any time. Mr. R. M. Kimball, vice-president of the Kenosha Gas & Electric Company, is the president in charge of the company. The offices are located at 1430 Old Colony Building, Chicago.

"NIAGRITE."—A material for preventing loss by fire and danger to life from the short-circuiting of high voltage electrical wires, for which the trade mark "Niagrite" has been adopted, is being placed on the market by the H. W. Johns-Manville Company. "Niagrite" is furnished in strips of several widths from 3 inches to 36 inches, suitable for wrapping spirally on electrical cables, and is held in place with asbestos fireproof glue, thus protecting the cables from external fire and confining any internal fire. The material presents a very neat and permanent finish and is not affected by atmospheric conditions. It has been adopted by the Niagara Falls Power Company, International Power Company, Buffalo Street Railroad Company, New York Edison Company, and other important electrical plants. Full particulars may be obtained from the asbestos department of the H. W. Johns-Manville Company, 100 William St., New York.

WATERBURY & COMPANY, of 69 South Street, New York City, Mr. George W. Nock, manager and electrical engineer, have issued the following notice to the trade: "On Jan. 1, 1904, we shall be completely equipped and prepared to fill orders promptly for all classes and kinds of electrical materials, special or standard. We shall be pleased to quote you on armature coils, field coils, or other windings, and to wind armatures complete for generators, motors, converters, etc.; also the designing and building of switchboards and special instruments, together with all special apparatus and materials required in electrical lines, and the laying out of complete installations for light and power purposes. Our plant is entirely new, and is planned with the idea of facilitating all orders, so as to give prompt and efficient service to all our customers at minimum prices. We guarantee all our goods to be the very best that knowledge and skill can produce."

OLD NEW YORK.—The Robins Conveying Belt Company, which has offices in the Park Row Building in this city, has just issued a very handsome broadsheet which is worth framing. It is two feet long by one foot wide, and shows New York as it was 250 years ago and as it is to-day, the contrast between the original old Dutch buildings and the sky scrapers of the present century being very remarkable. The oldest city was certainly as picturesque as the new, but in most other respects the new seems to have the advantage. Flanking the central pictures of old and new New York are two of buildings typical of the modern city. One shows the Flatiron Building and the other the Park Row Building, which is the highest in the world. We are sorry that the Robins Company cannot associate with this a picture of New York 250 years hence. The contrast between the city of that day and that of to-day would doubtless be as great as that between the two pictures now before us, and in the interim the Robins conveying belt has a lot of work cut out for it.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED JANUARY 12, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., N. Y.]

748,911. MACHINE FOR COVERING FLAT WIRE; James C. Anderson, Jersey City, N. J. App. filed April 30, 1903. The machine folds the edges of paper tape and then opens the folds and inserts ribbon wire therein.

749,160. ELECTRICALLY OPERATED RAILWAY SWITCH; Claude W. Breedlove and Rudolph R. Grant, Berkley, Va. App. filed Jan. 12, 1904. Details.

749,175. AUTOMATIC AND MANUAL FIRE ALARM; William Livingston Denio, Rochester, N. Y. App. filed May 14, 1903. Details.

749,178. WIRELESS SIGNALING APPARATUS; Lee De Forest, New York, N. Y. App. filed March 5, 1903. A Morse key having a curved arm projecting into a body of oil where the contacts are located.

749,185. ELECTRODE; Rudolf Hager, Halensee, Germany. App. filed Jan. 31, 1901. (See page 176.)

749,191. ELECTRIC SIGNALING APPARATUS; Felix B. Herzog, New York, N. Y. App. filed May 17, 1886. The principal feature consists in employing apparatus at a central station and the sub-stations whereby when the central operator manipulates the receiving apparatus, this will automatically indicate which of the sub-stations has signalled and will give in addition to this indication the signal which the transmitter has been prepared to transmit.

749,193. ELEVATOR; Nelson Hiss, New York, N. Y. App. filed Nov. 11, 1903. An endless cable arranged in two bights and moving always in the same direction, is caused to move the car one way or the other, or not at all, by varying the relative degrees of effort which the motor is permitted to exert upon the two bights of the cable, without changing the speed of the motor.

749,200. HIGH POTENTIAL SWITCH; John F. Kelly, Pittsfield, Mass. App. filed May 23, 1903. A circuit breaker, a device affording an easy path for abnormal frequency currents and a difficult path for normal frequency currents in series with a circuit breaker and means for cutting said device in and out of circuit.

749,204. ELECTRIC HEATING APPARATUS; Richard Kuch, Hanau, Germany. App. filed Nov. 7, 1902. The body to be heated has a strip of platinum foil applied to its surface for carrying the current, this material being of such a nature as to permit of close contact with the body.

749,213. ELECTROMAGNETIC DEVICE FOR VIBRATORY MASSAGE; Eugen K. Muller, Zurich, Switzerland. App. filed Sept. 20, 1902. An alternating current magnet actuating an oscillating knob through which the current passes when it is in operation.

749,224. COMPOUND APPLICABLE FOR INSULATING MATERIAL OR OTHER PURPOSES; Leonard M. Randolph, Newark, N. J. App. filed April 25, 1902. Varnish residue deprived of its liquid constituents.

749,225. TELEPHONE SYSTEM; Hope Redmon, Rufus L. Hall and Robert H. Conway, Cynthiana, Ky. App. filed Nov. 10, 1902. (See page 179.)

749,252. SYNCHRONIZER; Leonard Andrews, Manchester, England. App. filed June 25, 1903. For coupling alternating generators to the same circuit, a lamp indicator is operated without moving parts but through transformers having two primary windings and two secondary windings so connected to the generators, bus-bars and the indicator that one of the secondaries is excited when the current of both primaries are in phase and the other when the currents are in opposition.

749,255. ELECTRIC INTERLOCKING SWITCH AND SIGNAL SYSTEM; Gustave Bleynie and Theophile Ducousso, Paris, France. App. filed March 6, 1902. Details.

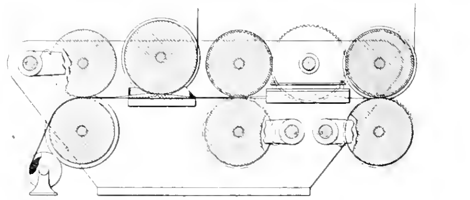
749,261. SWITCH; Troy Cope, New Waterford, Ohio. App. filed Aug. 20, 1903. Details.

749,268. ELECTRIC ARC LAMP; George R. Davison, Pittsfield, Mass. App. filed May 8, 1903. Such air as enters the globe through the carbon passage, must pass through a thin passage, the walls of which are heated, before it mingles with the gases in the globe.

749,271. ELECTRIC MOTOR CONTROL; Samuel T. Dodd, Pittsfield, Mass. App. filed June 4, 1903. A plurality of motors are controlled by shifting them from series to parallel while maintaining the connection of each armature to the corresponding field and using that armature and half of its field as an element in all combinations.

749,272. MOTOR CONTROL; Samule T. Dodd, Pittsfield, Mass. App. filed June 13, 1903. See preceding patent.

749,301. TROLLEY STAND; Washington H. Kilbourn, Greenfield, Mass. App. filed Aug. 14, 1902. Embodying among other details means for preventing the trolley pole from flying upward when the wheel leaves the wire.



748,911.—Machine for Covering Flat Wire.

749,306. TELEPHONE SYSTEM; Albion T. Libby, Chicago, Ill. App. filed Dec. 3, 1902. (See page 179.)

749,308. TELEPHONE-EXCHANGE; Frank A. Lundquist and John K. Norstrom, Chicago, Ill. App. filed Nov. 19, 1900. (See page 179.)

749,335. INSULATOR; Louis Steinberger, Brooklyn, N. Y. App. filed Sept. 18, 1902. A metallic sleeve is inserted in a porcelain insulator for strength, the sleeve then being filled with an insulating material and having a seat in its rear portion for the conductor.

749,336. INSULATED SUPPORT FOR WIRES; Louis Steinberger, New York, N. Y. App. filed Nov. 12, 1902. A clip for trolley wires in which a block of insulating material is inserted between the wire clamp and the supporting nipple.

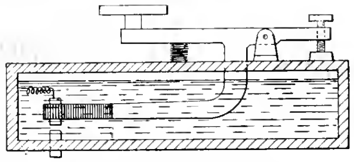
749,365. ELECTRIC BELL; Harry E. Dey, New York, N. Y. App. filed Aug. 15, 1901. A magnet having a reciprocating core projecting at both ends, is placed obliquely inside of two gongs, so that the core will strike one gong when moving in one direction and the other when moving in the opposite direction.

749,370. WIRELESS SIGNALING SYSTEM; Cornelius D. Ehret, Ardmore, Pa. App. filed Nov. 15, 1902. Consists in increasing the current of the received energy after having been transformed into the energy of currents in the receiving circuit.

749,371. WIRELESS TELEGRAPH RECEIVER; Lee De Forest, New York, N. Y. App. filed June 4, 1903. A magnetic detector for use with a duplex system whereby waves of other character than those for which the apparatus is designed, will not injuriously affect the receiving apparatus.

749,372. ART OF WIRELESS TELEGRAPHY; Lee De Forest, New York, N. Y. App. filed June 4, 1903. The method of sending a warning signal consisting in emitting a recurring series of high frequency waves varying both in their spark frequencies and in their continuity in accordance with a predetermned cycle, and in translating the waves into audible sound.

749,387. AUTOMATIC NON-INTERFERING REPEATER FOR FIRE ALARM CIRCUITS; Wm. H. Kirnan, Bayonne, N. J. App. filed Oct. 4, 1902. Non-interference magnets corresponding with the street-box magnets, prevent the operation of the repeater by any one of the street magnets while under the control of any other of them.



749,178.—Wireless Signaling Apparatus.

749,391. BOND FOR CONDUITS FOR ELECTRIC WIRES; George A. Lutz, New York, N. Y. App. filed May 7, 1901. A corrugated metal strap embracing the joint of conduit sections.

749,392. ELBOW FOR CONDUITS FOR ELECTRIC WIRES; George A. Lutz, New York, N. Y. App. filed May 7, 1901. The cover of the elbow is confined by lugs located at intervals around the curve and bent over the edge of the cover.

749,399. ALTERNATING CURRENT RELAY; Greenleaf W. Pickard, Amesbury, Mass. App. filed Aug. 21, 1903. A novel electro-magnetic movement actuated by alternating currents and employing three pole pieces, one of which is movable between the other two, and a coil embracing the movable pole and one of the other two pole pieces, the object being to provide a call receiving apparatus promptly responsive to alternating currents of high frequency and equally responsive reversely to the cessations of such current.

749,401. ELECTRIC RAILWAY; Leon W. Pullen, Philadelphia, Pa. App. filed April 18, 1903. Details of a system wherein magnets carried by the car actuate circuit controllers in the road bed to energize contact studs fixed at suitable intervals along the way.

749,409. IGNITING DEVICE FOR ACETYLENE GAS BURNERS; Henry C. Thomson, Boston, Mass. App. filed Nov. 6, 1902. Details.

749,416. SAFETY APPLIANCE SYSTEM FOR ELECTRICALLY ACTUATED ELEVATORS; Harry G. Wright, Providence, R. I. App. filed May 9, 1903. Relates to that class of machine adapted to automatically prevent the car from moving in case any of the landing doors are not fully closed.

749,418. METHOD OF MAKING CARBON ARTICLES; Edward Goodrich Acheson, Niagara Falls, N. Y. App. filed Sept. 4, 1902. (See page 176.)

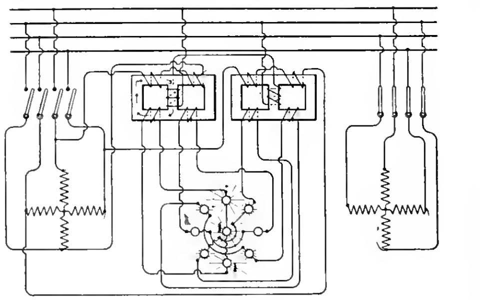
749,426. LIGHTNING ARRESTER; William E. Cone, Memphis, Mo. App. filed May 28, 1903. Details.

749,434. WIRELESS SIGNALING APPARATUS; Lee De Forest, New York, N. Y. App. filed June 4, 1903. The spark determining member of the transmitting apparatus cuts the indicating member of the repeating apparatus out of the circuit during the time of each spark in the transmitting apparatus.

749,435. GENERATING SET FOR WIRELESS TELEGRAPHY; Lee De Forest, New York, N. Y. App. filed June 17, 1903. The set comprises an explosive engine, a dynamo, a choke-transformer, step-up transformer, a sparking circuit and a radiating conductor.

749,436. WIRELESS TELEGRAPH RANGE FINDER; Lee De Forest, New York, N. Y. App. filed June 17, 1903. A distance indicator comprising a variable resistance adapted to be inserted in the circuit with the indicating device in quantities having values proportioned to different distances.

749,439. ELECTRICAL CONTROLLING APPARATUS; John D. Ihlder, Yonkers, N. Y. App. filed March 22, 1902. The speed of an alternating current motor can be automatically changed while it is in operation.



749,252.—Synchronizer.

749,442. OUTLET BOX; Hubert Krantz, Brooklyn, N. Y. App. filed May 25, 1903. The openings are covered by removable disks which are held in place by radially projecting ears.

749,448. TELEPHONE-TRANSMITTER; Philip G. Randall, Boston, Mass. App. filed Feb. 9, 1903. (See page 179.)

749,460. ELECTRIC FURNACE; LeRoy W. Stevens and Bernard Timmerman, Chicago, Ill. App. filed Aug. 8, 1902. (See page 176.)

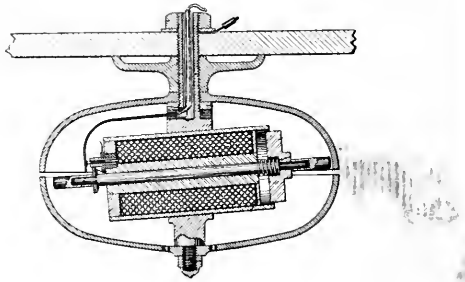
749,461. ELECTRIC FURNACE; LeRoy W. Stevens and Bernard Timmerman, Chicago, Ill. App. filed Oct. 29, 1902. (See page 176.)

749,462. FURNACE; LeRoy W. Stevens and Bernard Timmerman, Chicago, Ill. App. filed Oct. 30, 1902. (See page 176.)

749,481. TELEPHONE REPEATER; Merritt Gally, Brooklyn, N. Y. App. filed April 18, 1903. (See page 179.)

749,495. ELECTRIC STRIKING CLOCK; William Olson, Jersey City, N. J. App. filed Dec. 31, 1902. Details.

749,500. MINER'S ELECTRIC LAMP; Henry G. Prested, Camden Town, England. App. filed Feb. 7, 1903. The combustible gas diffusing through a porous diaphragm at a rate different from that at which air diffuses, is utilized to move a contact controlling the circuit of a glow lamp.



749,365.—Electric Bell.

749,509. TROLLEY; Willis D. Williams, Kirkland, Arizona Ter. App. filed Aug. 19, 1903. The flanges of the wheel are flanked by spiders, the arms of which project to retain the wheel on the wire.

749,584. WIRELESS SIGNALING SYSTEM; Harry Shoemaker, Philadelphia, Pa. App. filed Oct. 3, 1902. A plurality of local circuits controlled by the wave-responsive device, each circuit containing means for selecting a certain message to the exclusion of other messages which may be simultaneously received.

749,597. ELECTRIC RAILWAY SWITCH; Johann G. Weniger, New York, N. Y. App. filed June 9, 1903. Details.

749,601. TROLLEY HARP DEVICE; Frederick H. Allen, Dunkirk, N. Y. App. filed Nov. 2, 1903. A construction enabling the wheel to be quickly removed and replaced.

749,628. ELECTRIC HEATER; George J. Peacock, Pittsburg, Pa. App. filed April 19, 1902. An electric heater embedded in protective material surrounding a water plug.

749,633. ELECTRICAL HOSE SIGNALING APPARATUS; William G. Seeley, Brookline, Mass. App. filed May 25, 1903. Details of the joint for maintaining the continuity of the circuit

749,657. AMUSEMENT AND ADVERTISING DEVICE; Miles W. Beemer, New York, N. Y. App. filed Jan. 5, 1903. A miniature lighthouse with a battery and motor in the base whereby the light shows alternately white or red.

749,694. MEANS FOR DETERMINING THE NAUTICAL BEARING OF NAVIGABLE VESSELS; Hermon W. Ladd, Boston, Mass. App. filed May 15, 1899. A conductor for catching Hertzian waves is shielded on all side except one, the shield being mounted to rotate and to carry with it an index that plays over a compass dial. When a signal is received, the position of the index indicates the bearing whence it came.

749,705. REGULATOR FOR INCANDESCENT LAMPS; Frederick C. Schofield, Washington, D. C. App. filed May 7, 1903. Details of a rheostat placed in the socket of the lamp.

749,710. ELECTRIC BLOCK SIGNAL SYSTEM; Louis C. Werner, Broadbrook, Conn. App. filed Dec. 12, 1901. A four-position semaphore and means for locking it at each position.

Electrical World and Engineer

THE UNION ENGINEERING BUILDING.

Stage by stage the great Union Engineering Building project, due to Mr. Andrew Carnegie's munificence, advances to successful issue. The American Society of Civil Engineers, at its meeting last week, decided to canvass its members, and although many objections to union were raised, it is hardly to be believed that the civil engineers of the country will want to reject their share of the gift or imperil that of the sister societies, especially after Mr. Carnegie has just added $500,000 to the original $1,000,000 in order to take full care of the necessities of all the societies, if the Civils should "come in." However, in its broadest aspect, the matter is now "up to" the Civils; and we do not hesitate to say, knowing whereof we speak, that the Electricals count confidently upon their co-operation. In the early days of struggle, the Electrical Engineers were fostered by the Civils and always made at home at the old house in East Twenty-third Street; and it is sanguinely hoped thus to cultivate again at no distant date, in a grander, more splendid, more comfortable, place, the close fellowship of the past.

The Civils have been told that if they do not come in the project thereby falls to the ground. Should this be true, their responsibility would, indeed, be great, and we have no objection to their understanding it in that manner. But it is not true, and it is best that at each stage there should be the fullest light and understanding on the scheme. President Noble last week quoted apparently a remark of Mr. Carnegie, that he was likely to have five lots on his hands; but that Mr. Noble gravely misunderstood him seems at once evidenced, by the fact that last week also Mr. Carnegie acquired another lot, making, we believe, six in all, and bringing his generous investment in land which he is carrying for the societies—over and above the million and a half—to more than $600,000. It will be seen that this fact and Mr. Noble's theory, anxiously put forward by him to help bring his fellows into line, are not consistent or harmonious.

The various bodies can rest assured that Mr. Carnegie does not propose to see his magnificent ideas and purposes frustrated; it would be the first time in his history. Moreover, it would present the spectacle of a strong and wealthy society deliberately reaching forth its hand to prevent other societies less well off, but able to apply the endowment very beneficially, from receiving a single cent. That aspect of the case has only to be mentioned to show its improbability not less than the sinister interpretation the wide, outside world would bestow on such an action. The renewed and extended primacy in engineering matters which belongs to the Civils and has been deservedly won, will, by acceptance of the gift, be one of the brightest of auguries alike for the wider influence of the society and for the future of the profession.

NORTHWESTERN ELECTRICAL CONVENTION.

Elsewhere we print that part of the proceedings of the convention of the Northwestern Electrical Association not convered in the telegraphic report which appeared in our pages last week. As will be seen, the character of the papers read and the interest manifested in the proceedings show no falling off from the previous meetings of this flourishing association. As has almost invariably been the case in recent years when it came up, the topic which appeared to appeal most directly to the audience was that of central station auxiliary heating service. Indeed, at the meetings of all the associations representing the smaller central stations, this subject, when on the programme, arouses, judging from its lively discussion, even more interest than the most timely electrical topic. From the experiences related in such discussions it appears that the distribution of heat in connection with a lighting service can, without doubt, be made a profitable business in smaller towns and cities if a proper plant is installed and intelligently managed, and adequate rates are charged. Another advantage of such an appendage to a central station plant pointed out at the convention is that the combination offers a safeguard against the intrusion of a competitor in the lighting field, and the establishment of a municipal electric plant. In view of this situation the interest taken is well justified, and smaller central stations everywhere should not neglect to examine into the advisability of adopting heat distribution in connection with their lighting business.

Alternating-Current Power Curves.

It is known that when an alternating e.m.f. drives an alternating-current in a circuit, the power pulsates between a maximum and zero in the non-inductive condition, or between a maximum positive and lesser maximum negative quantity, when the load is inductive. The pulsation of power has twice the frequency of either alternating pressure or of the alternating current. Mathematical proofs of this proposition by several writers are to be found scattered through the polyglot literature of alternating-current technology. An additional demonstration is given in an article on page 215 by Mr. W. J. Berry. It follows that if a wattmeter mechanism could be constructed of sufficiently small periodic time, it would pulsate with twice the frequency of the generator assumed as bipolar. If this wattmeter mechanism drove a new bipolar generator, the frequency in its circuit would be double that of the first generator. By successive concatenations of wattmeter mechanisms to generators, the frequency might be redoubled indefinitely. Such an arrangement is probably quite impracticable, but it forms an interesting ideal method of frequency multiplication. The late F. Jarvis Patten at one time took up the investigation of the subject and devised some ingenious means for arriving at practical results.

Electrical Foucault Pendulum Systems.

The name of Foucault is not only associated with eddy currents, or electric whirls, in metallic masses, but also with the demonstration of the variation of the plane of vibration of a pendulum. The public demonstration which he made in 1851 at the Paris Pantheon, by swinging a pendulum from the dome, dominated popular fancy, and perhaps first made clear to the ordinary conception the rotation of the earth about its axis. His pendulum consisted of a 28-kilogram bob suspended by a steel pianoforte wire from the dome ceiling. The length of the pendulum is recorded as 67.21+ meters, so that the time of a single swing was 8.2 seconds, or 16.4 seconds for the complete period. There were thus less than four complete swings per minute. The angle of initial displacement was about 10°, and the pendulum was started from this displacement by burning the deviating thread. At a radius of four meters a ring of sand was raised, which was chiseled by a point on the bottom of the swinging bob. If the pendulum had been erected at the North Pole it would, naturally, tend to swing in its original plane, while the earth moved around beneath it, thus bringing the entire ring of sand through one complete revolution in 24 hours. This would mean an apparent advance of the bob along the sand at the rate of 25.13 meters in 24 hours, or 1.047 meters per hour, or 1.744 centimeters per minute; or 4.77 millimeters per complete swing. But the Pantheon at Paris, instead of being at the North Pole, or in latitude 90°, was in 48° 50′ 49″ north latitude, according to the record, and the deviation of the plane of vibration would be less than that at the Pole in the ratio of the sine of this latitude, or 0.7529. This would reduce the cut into the sand at each successive swing from 4.77 millimeters to 3.59 millimeters (about one-seventh of an inch), and the observed rate of cutting is said to have agreed with this result.

The trouble with this beautiful experiment was naturally the continual diminution of the successive swings. The rate of decrement is not stated; but the original stock of energy being limited to about 2,800 megergs at 10° original deviation, the continual frittering away of this energy in air friction and wire bending would soon greatly enfeeble the swings. Consequently, charming and instructive as the demonstration must have been, it was necessarily but short-lived. Real luxury in such a case would be to restore energy to the swinging bob without perplexing it, or affecting its plane of vibration, and thus to keep it going at full amplitude indefinitely. At the end of 24 hours the bob should have cut down the little sand bank to the extent representing the sine of the latitude, or 75.29 per cent. of a complete rotation in relative space. Probably elaborate precautions against tremors and air currents would become necessary in making the measurement under such ideally luxurious conditions. But after due care had been expended in safeguarding the plane of vibration from accidental disturbance, the perennially-reinforced pendulum ought to work out its own latitude very nicely in this way.

Another form of the mechanical system capable of revealing persistence of motion is the gyrostat, or rapidly-revolving small fly-wheel, whose axis tends to remain in the original direction, and to permit all terrestrial things to move around according to the earth's rotation. In fact, the pendulum may be looked upon as a particular form of the gyrostat, in which the rotation is incomplete and oscillatory. Of course, the gyrostat also suffers from the decay of initial energy, and only scorns the earth's movement for but a brief interval. The problem of reinforcing a gyrostat or pendulum, without disturbing its plane of vibration, has been considered by various writers, and electrical means have been favorites. It seems almost impossible to restore energy by mechanical force, through the medium of any contact with the moving parts, without at the same time exerting a bias or disturbing force on the plane of vibration. For example, the ordinary pendulum clock restores enough energy at each beat of the pendulum, from the mainspring or driving weight, to make up for the loss during the preceding beat; but in this case the plane of the pendulum is kept definite and moves around with the earth.

In the article on page 211 Mr. E. K. Adams considers various electromagnetic pendulums, and suggests a variety of ingenious electric expedients for maintaining the amplitude of vibration. It is, of course, hard to foresee the minor difficulties that may arise in the operation of such devices, but it would be very interesting to develop a working apparatus of this kind. At least one of the forms described should be capable of operating successfully. Such an apparatus, actually maintaining itself at full amplitude of vibration for a day at a time, would be both interesting and instructive; but its utility would be seemingly confined to interest and instruction. Any apparatus, however, which could be devised to operate automatically in spite of jars, or swings of its support, would, if not too expensive, be of great practical value. Possibly it would be hopeless to control the pendulum on board a rolling ship at sea; but it might be within the range of possibility to work a gyrostat electrically at a very high speed, so as to retain its direction of motion in gimbals, regardless of the behavior of the ship. If this could be done, the navigator, by running the apparatus during a measured time, might be able to compute the latitude, from the deviation of the plane of motion, by compass, during that period. Such a plan, if it could be made effective, would be available for latitude observations at sea, in fog, or darkness, or near the land.

ELECTRIC CONVECTION.

The December number of the *Physical Review* contains an important report by Messrs. Cremieu and Pender on the magnetic effect of electric convection, the conclusions of which we printed last week, and to which, owing to the unusual interest of the subject, we now return. The fundamental theory of electromagnetism declares that there are two kinds of electric currents, namely, currents of conduction, such as are guided by a wire forming a closed conducting circuit, and currents of displacement, such as are formed by electrostatic displacement in a dielectric. The conduction current is typically presented in a direct-current circuit, while a displacement current is presented in a condenser connected to an alternating e.m.f. The characteristic requirement of a conduction current is a wire or conductor. The characteristic requirement of a displacement current is an insulator subjected to a variation of electric force. It is also fundamental that whatever the nature of a current of given strength, by conduction, or by displacement, the magnetic effect is the same. An ampere of displacement current entering a condenser will have the same magnetic behavior as an ampere of conduction current in an overhead wire, allowance being made for the different geometrical distribution in the two cases.

In fact, we may be said to know that a conduction current is of the same nature as a displacement current, for the latter is a production of electric flux in a dielectric by electric charge, or electric potential difference; and the former is a movement of electric flux in a dielectric surrounding a guiding conductor. In a condenser, the varying electric flux which constitutes a current, is due to the variation of potential between the two opposed surfaces. In a direct-current circuit, the electric flux changes by running along the wire. Magnetic action accompanies change or motion of electric flux, and it should not matter how the change in electric flux is produced. The magnetism merely depends upon the change. If we take a charged body, say an electrified gilded billiard ball suspended by a silk thread, we know that electric flux emanates from the ball radially in free space, and very nearly radially in the middle of an ordinary room. When we move the electrified ball, as by swinging it, the electric charge moves also, and the electric flux moves conformably. That is, flux permeates the air in regions that were not previously permeated to the same degree, and vacates other regions that were previously more thoroughly permeated. This means, according to accepted theory, the establishment of displacement currents. It also means, by the same theory, the production of magnetic action in the neighborhood, during the motion. Consequently, when the electrified ball is stationary, there will be electric flux at rest, but no current and no magnetic action. When the ball is moving, there will be both current and magnetism. Moreover, the current and magnetism should increase in intensity with the speed of movement.

Maxwell predicted this result in 1873. The late Prof. Henry Rowland published experimental results in 1878, showing that the magnetic effect of a moving charge existed. It was commonly called the Rowland effect. Rowland rotated a disc with a charged conducting surface inside a box, and delicately supported a magnetic needle over the rotating disc outside the box. When the rotating disc was charged, or grounded, or reversed in electrification, the magnetic needle behaved in reasonable accordance with theory. It would be a serious matter for the present electrical theory if the effect could not be found. In fact, it may be said that if persistent effort showed that the magnetic effect of electric convection did not exist, it would kill the theory, and the death of the theory would upheave all our notions concerning electricity, which have been slowly and steadily put together by more than a century of the world's electrical labors. In 1884, however, Lecher tried the experiment in a somewhat different way, and failed to detect the effect. The magnetic effect to be expected is, however, very feeble at any speed and electrification that can be conveniently employed in a laboratory; so that the fact that a single observer did not obtain the effect, did not make electricians feel very uncomfortable, seeing that one good observer said he had found the effect. Negative evidence is not nearly so definite as negative electrification. Röntgen tried the experiment in 1885 and reported that he obtained the effect. Prof. Rowland and Dr. Cary T. Hutchinson repeated Rowland's original experiment in 1889, on an enlarged scale. They employed a pair of discs running in condenser boxes at high speeds, and with delicate magnetic needles outside. The effect was obtained within about 6 per cent. of its theoretical amount, the maximum variation being about 25 per cent. above or below. Prof. Himstedt took up the experiment about the same time and obtained the effect in a substantially similar manner.

So far only one observer of known ability had failed to obtain the effect. But in 1897 M. Victor Crémieu, of Paris, took up the experiment, or rather a whole series of experiments, and failed to get the effect. He went so far as to say, in 1901, that the effect was a myth. Theory showed that the effect was very minute under laboratory conditions; but positively declared that it must be there. So when Crémieu declared that the effect was certainly not there, consternation awoke. Crémieu worked for several years on the question and kept publishing papers to show that his experiments were all negative. In 1901 Pender, under Rowland's directions, repeated Rowland's experiments and made a long research into the matter, using a pair of discs revolving at high speeds. He obtained the effect within 2 per cent. of the theoretical amount, and within a maximum variation of 8 per cent. Pender kept repeating his experiments and getting the effect on this side of the Atlantic, while Crémieu kept repeating his experiments and not getting the effect on the other side of the Atlantic. Eichenwald, in Europe, recently repeated Rowland's experiment, with certain modifications, and got the effect, while Adams, in England, rotated electrified spheres, fastened to the spokes of a pair of wheels, and also obtained the effect.

In 1902 Poincaré suggested that Pender, who always got the effect, should meet and collaborate with Crémieu, who always did not get it, so as to arrive at a joint result. Lord Kelvin suggested that the joint research should be made in Paris. Johns Hopkins University placed the apparatus used by Pender at his disposal for transportation, and the Carnegie Institute defrayed the expense of his journey. M. Bouty placed his laboratory in the Sorbonne at the disposal of the two investigators, while the expense of their experiments was met by the Institute de France. The two men worked together for about three months. They finally report jointly that the effect is found. Incidentally, they trace the negative results previously obtained by Crémieu to the influence of certain thin layers of solid insulating material fastened to the surfaces of the revolving electric conductor. Just how these insulating covers prevented the effect is not clear, but it will probably be investigated. The real value of the joint report of Crémieu and Pender, recently published, lies not only in the final establishment of the magnetic effect of a moving electric flux, as required by theory, but also, and more particularly, in the international co-operation of scientific organizations to bring about this result. This international scientific co-operation is of enormous potential importance, and every effort should be made to foster it. Electrical science owes much to both of these joint observers for their collaboration.

Institute Annual Dinner.

Notices have been issued this week to members of the American Institute of Electrical Engineers, with regard to the annual dinner at the Waldorf-Astoria on February 11. As already stated, the price of tickets for gentlemen, without wine, is $7, and for ladies, $5. In addition to this, provision is also being made for admission to the boxes in the galleries of the ballroom at $1 per ticket. Mr. Calvin W. Rice, chairman of the committee, believes that a large number of persons will be glad to avail themselves of the opportunity thus to be present at a function which takes on a rather more historical and memorial character than the ordinary banquet, and it is not unlikely that the galleries may be filled with quite a large audience in addition to the guests at dinner on the main floor. It may be noted as an item of news that the menu being prepared will include a fine portrait in colors of Mr. Edison, being the gift to the Institute for that purpose by the New York Edison Company.

The Edison Medal Association is, of course, co-operating actively in the plans for the dinner, and many subscribers to the Fund, not members of the Institute, will be present. A large number of subscriptions to the Institute Edison Medal have been received, and the fund is already an assured success; but it is desired that it shall reach the full sum set forth in the circulars, in order that liberal provision for the foundation may be made in every respect. The suggestion has reached the Association that many of those who derive their living from the industries created by inventions in the lighting field would like to contribute also to the Fund, and the Association has prepared lists which are obtainable by companies desiring thus to contribute to the Edison Medal, the first, it is said, which has ever been offered in the field of electricity as an encouragement for studious and ambitious young men. Amounts of $1 and less will be received, and the lists of names will be bound into the album which it is proposed to give Mr. Edison containing the autographs of all the contributors.

Equipping the Erie Canal Electrically.

The question of equipping the Erie Canal electrically is just now attracting a great deal of attention, especially as a result of the tests described recently in these pages. Mr. Charles S. Boyd, superintendent of public works, believes that he can grant an indeterminate right to the International Towing & Power Company to install a similar electric towing plant the entire length of Champlain Canal. But in the first place, the law of 1893 permits him to allow only the temporary erection of a towing plant for testing the "efficiency, economy and practicability" of such device. It conveys no power which would enable any experimenters to do business and charge tolls. In the second place, the law restricts the experiments to corporations "authorized to transact business within this State," and this authorization, it is said at the Secretary of State's office, the towing company mentioned has not received. In the third place, the State Constitution forbids the lease, sale or other disposition of the canals. This is construed to mean that the canal banks, beds, towpaths, etc., are to be kept in the possession and management of the State forever, and that no exclusive privilege to do towing could be granted.

It is contended on behalf of Mr. Boyd's position that Section 38, Article 3, Chapter 338, Laws of 1894, gives warrant for his point of view. This provides that "the Superintendent of Public Works may authorize from time to time any person or corporation to construct, maintain and operate electric conductors for light, heat or power upon or along any canal, on such terms and conditions, not inconsistent with the public use of such canal, as he approves; in like manner contract for or permit the use of such light, heat or power upon any such canal, but not to create a charge against the State except against appropriations lawfully applicable thereto."

Justice Herrick's recent decision, enjoining a man from cutting ice on the canal without a permit from the Superintendent of Public Works, seems also to recognize the large power of that officer over the canals. He may grant or refuse permission to cut ice wherever he wills.

Precedent for the giving of a permit to an electrical towing company is indicated in the case of the Cataract Electric Company. In 1894 Superintendent Hannan issued a permit to that company to put up pole lines, etc., along the canal.

The Automobile Club Annual Dinner.

The Automobile Show in New York City came to a most successful close last week, the attendance being estimated at 50,000 and upwards, while the sales are also reported to have been very large. A fitting finale was given by the annual dinner at the Waldorf-Astoria on Saturday night, attended by over 300 guests, with about 100 ladies in the boxes, in addition. A notably large number of electrical men were present, and Mr. T. A. Edison occupied a prominent seat at the speakers' table. The decorations and electrical effects were admirable. The speaking also, under the skillful guidance of President Scarritt, was excellent. The keynote of the evening, as usual, was "good roads," and hearty endorsement was given by speakers and audience alike to the Brownlow measure now before Congress to spend $20,000,000 on the betterment of the main roads of the United States. Among those present were Messrs. L. R. Alberger, W. H. Baker, W. G. Bee, Hart O. Berg, E. T. Birdsall, N. F. Brady, A. H. Chadbourne, G. H. Day, C. J. Glidden, W. C. Gotshall, J. M. Hill, John A. Hill, Walter H. Johnson, W. C. L. Eglin, F. A. La Roche, T. C. Martin, Lewis Nixon, P. T. Dodge, A. R. Pardington, A. L. Riker, Henry Sanderson, J. Seligman, Angus Sinclair, E. L. Powers, H. M. Swetland, R. A. C. Smith, A. H. Whiting, C. C. Worthington and others in the electrical and allied fields.

World's Fair Electric Railway Test Commission.

A second meeting of the Electric Railway Test Commission of the Universal Exposition, St. Louis, 1904, convened in New York on January 27, 1904. All of the commissioners, namely, Mr. J. G. White, chairman; Mr. H. H. Vreeland, Mr. James H. McGraw, Mr. George F. McCulloch, Mr. W. J. Wilgus, were present, and a great deal of work was accomplished in furthering the plans for an elaborate series of tests of electric railway equipment at the Exposition. Much interest has been manifested by electrical engineers in the proposed tests, and the value of the engineering data which in all probability can be accumulated in this way, is not to be overestimated. The tests will undoubtedly have the effect of greatly stimulating interest in electric railway undertakings and promoting development along the lines best adapted to meet effectively the conditions most prominent in different classes of service.

The work has been divided into four main divisions, and special committees of engineers, who are specialists in the several divisions of electric railway work, have been appointed to prepare a schedule of the tests which will be made of the equipment offered in each class. These special engineering committees on the scope of the tests will take cognizance of the following branches of work: City and suburban equipments, interurban equipments, heavy traction equipments, new systems of electric traction. The committees are expected to prepare and submit preliminary reports to the commission on or before February 22, and the next meeting of the commission will take place in New York City, on Monday, February 29, at which time the reports of the special committees will be reviewed and passed upon.

High Speed in Germany.

A special cable dispatch from Berlin, of January 26, says: "Before the budget committee of the Prussian Diet to-day, Minister of Public Works Budde, discussing the recent electrical rapid transit experiments, said:

"The studies are still in their preliminary stages. We cannot undertake the transportation of the general passenger public electrically. It is still uncertain whether such roads can be economically profitable. The experiments will be continued with necessary precautions. The operation of the suburban road from Berlin to Grosslichterfelde gives the most favorable results, and we shall soon see the practical introduction of electricity on the Hamburg Elevated Railroad. The Prussian Railroad Administration will utilize the results of all these experiments."

The Siskiyou Power Transmission.

THE power house of the Siskiyou Electric Power Company is situated on Fall Creek, a tributary of Klamath River, eight miles from the well-known Klamath Hot Springs, two miles south of the Oregon line, in California, and twelve miles from Lairds, on the main line of the Southern Pacific Railway traversing California and Oregon. The power house is situated within 300 ft. of the Klamath Lake Railway, which made it very convenient for getting supplies on to the ground for the construction of the power house, pipe line and other work. The water for the operation of the plant is delivered from two creeks; one, Fall Creek, so named from the beautiful water falls along its course, supplies 1,500 miners' inches; and the other, Spring Creek, so named from the fact that its source of supply is in a great spring, supplies 700 inches. These creeks might have been named from the two respective seasons to denote that their water supply is continuous through spring and fall, as the flow of 2,000 miners' inches is uniform the year around. The supply appears to come from the drainage of a large area of tableland extending over thirty miles, where no water courses are to be found outside of these two creeks, which are evidently the drainage of this territory. Their chief peculiarity, however, is the fact that they do not freeze in winter because of their origin in and transit through a volcanic country.

A small wingdam has been built across Spring Creek for diverting the water into a 3,000-ft. ditch, which carries it first through a backbone of a mountain and thence to the main channel of Fall Creek. This ditch is 3 ft wide at the bottom, 6 ft. at the top, 3½ ft. deep and is built on a grade of 5 ft. to 100 ft. The course of Fall Creek ditch lies almost entirely through rock of volcanic formation, and it begins one mile above the upper falls of Fall Creek, from which it takes water by means of a diverting dam 115 ft. long and 4 ft. high. Very little work was necessary to put in this dam, as all natural conditions were favorable to it. The Fall Creek ditch is 4,650 ft. long, being 6 ft. wide at the bottom, 5 ft. deep and 12 ft. wide at the top, built on a 5 per cent. grade. The velocity is 3¾ ft. per second, which gives the ditch a capacity of 2,000 miners' inches. The only piece of flume in the work is a stretch of 96 ft. leading from the ditch to the penstock, it being 6 ft. wide by 4 ft. high and laid on solid rock. The penstock is solidly built on a cement foundation, laid on 12 by 12 timbers; that is, 14 ft. square by 16 ft. deep, and its walls are made up of 2-in. plank 6 in. wide, piled up flat one above the other. This wall is lined with a ⅛-in. coating of P. & B. roofing material, after which it is surfaced with 2-in. tongue and groove flooring. The whole penstock is braced with rods and turn-buckles extending diagonally across its section; finally it is painted inside and out with P. & B. paint and roofed over.

FIG. 1.—POLE LINE CONSTRUCTION.

FIG. 2.—VIEW OF MAIN DITCH.

FIG. 3.—GATE VALVE.

The pipe line is made of double-riveted steel pipe in the following lengths, the enumeration beginning at the penstock and extending downward: 37 ft. of pipe, 40 in. tapering to 30 in., of No. 10 gauge steel; 800 ft. of pipe, 30 in. No. 10 gauge steel; 700 ft. of pipe, 30 in. No. 6 gauge steel; 800 ft. of pipe, 30 in. ¼-in. steel; 500 ft. of pipe, 30 in. ⅝-in. steel.

The receiver is 60 ft. long, 30 in. in diameter, and made of 7/16 steel. From it there are taken three 12-in. taps for the respective three water wheels. From penstock to nozzle the head is 715 ft., giving a static pressure of 310 pounds to the square inch. A 30-in. hand-operated gate, which weighs 12,000 pounds, and which is provided with a 4-in. bypass gate, is inserted in the pipe line in the manner shown in the accompanying illustration, before the pipe line enters the receiver.

FIG. 4.—DIVERTING DAM.

The power house is constructed of a light steel frame, covered with corrugated iron. The main building is 30 ft. by 57 ft. in ground area, and the transformer room, which is separate from it—a similar building—measures 14 by 20 ft. in size. A 7-ton traveling crane runs the entire length of the main building, the latter being designed to contain three generator sets, one of a capacity of 500 kw and the other two to be of a capacity of 750 kw each.

At present there is installed one 2,300-volt General Electric generator, direct-connected to a 62-in. Pelton water wheel of two bearings and with a flexible coupling. This water wheel has a capacity of 1,000 hp. The whole is set on a concrete foundation built up of one part cement, two parts of sand and three of gravel, extending 8 ft. below the surface of the ground, which is of the ordinary lava formation mixed with a sort of cemented clay. A Lombard governor controls the generator, the exciter for which is a 125-volt General Electric generator, run by an 18-in. Pelton water wheel that overhangs on the exciter bearing. The switchboard consists of one main generator panel, one exciter panel, and one low-tension panel, all being provided with oil switches and everything in connection with the switchboard being of latest General Electric design.

The transformer house contains three General Electric water-

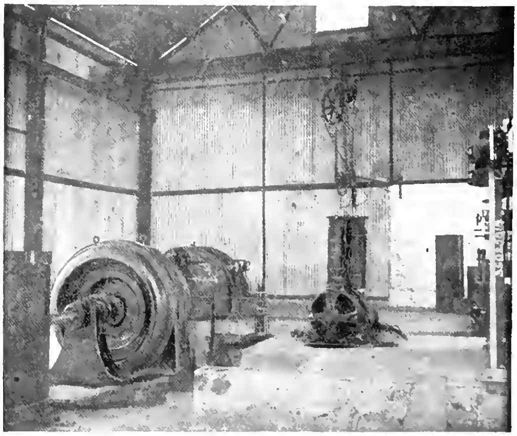

FIG. 5.—FIRST GENERATOR INSTALLED.

cooled transformers having a capacity of 167 kw each, the primary voltage being 22,500 and the second voltage being 2,300. There are also installed in the transformer house three lightning arresters and one high-tension oil switch panel.

The circuit extends in a direct line running southwest from the power house on Fall Creek to Yreka, a distance of 22 miles, whence it continues on in another direct line tending west by southwest, passing the base of Humbug Mountain to New York Mine, 14 miles beyond Yreka. Almost due south of the New York Mine and separated 7 miles from it by way of the pole line is Fort Jones, whither the line also reaches, thus making the total length of the main line

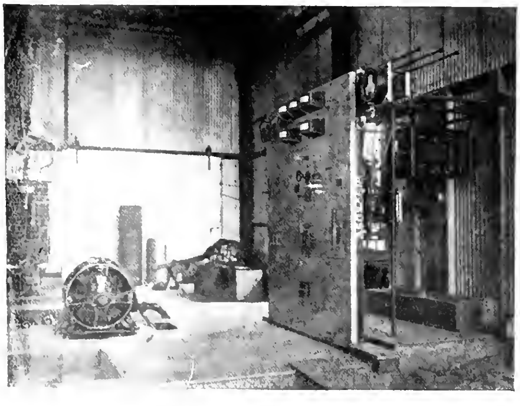

FIG. 6.—POWER HOUSE SWITCHBOARD.

to be 43 miles. The Hornbrook line is tapped from the main line at its crossing over Bogus Creek, which is a little less than one-half the distance from the power house to Yreka, and just before entering Yreka another branch line, which runs to Montague, a station on the Southern Pacific line to Oregon, is tapped off the main line. From Montague this extension is continued on across the base of Mount Shasta in a direct line to Little Shasta Mill. The length of the Hornbrook branch is six miles, while that of the Montague branch is close to 14 miles. All the line is of aluminum three-strand No. 4 cable, using Locke insulators with glass top and petticoat, and designed for a working pressure of 40,000 volts. The pins are eucalyptus, 1½ in. x 12 in. in size and are boiled in oil. The cross arms are of Washington fir, boiled in oil and painted. The poles are round, of red fir, 30 ft. long, with 7-in. iron-shod tops, creosoted at the butt and in some places tarred.

Current was turned on September 12th, and the business consists of both lights and power service. The towns of Montague, Yreka, Fort Jones and Aetna in California are already supplied, while Ashland, Medford, Jacksonville and Phœnix in Oregon will be supplied with electric service. The plant was started with 300 lights at Montague, 400 lights at Fort Jones, 75 hp at the New York Mine, and 125 hp at Punch Creek, near Yreka. Besides lighting and general industrial power service, a large power field will be found in the mines now operating, and which hitherto have been only prospective,

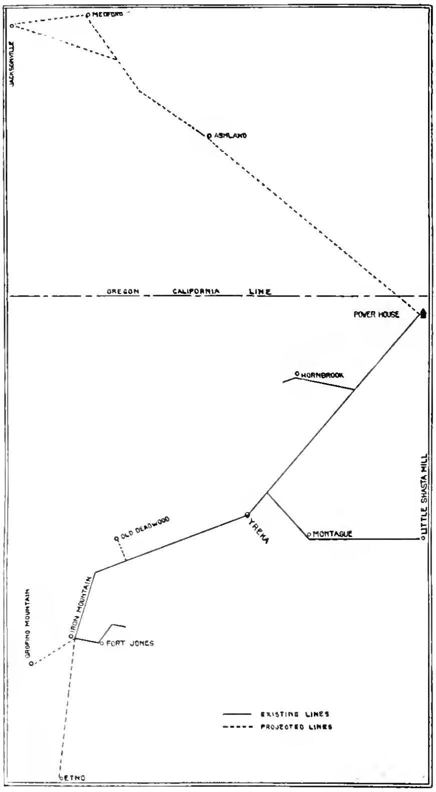

FIG. 7.—MAP OF ROUTE OF LINES.

due to the lack of economical and convenient power. Another field which will take up a large amount of power, although in small units, will be pumping for irrigation. Large tracts of land, that are not now under cultivation, have an abundant supply of water within 10 or 12 ft. of the surface and with electric power these lands will be brought into commission through pumping. Considering the reliability of the water supply and the rich country that is reached by the pole lines both present and prospective, a large and prosperous business is undoubtedly in store for the company.

Telephone Distress Signal.

A correspondent at Indianapolis states that at Anderson, Ind., the Farmers' Telephone Company has adopted a general signal of distress for its patrons on party lines. Following the general alarm the exchange operator will give the number of rings indicating the house from which the alarm came so that the neighbors may go direct to the place where assistance is needed.

Electrical Foucault Pendulum Systems.

By ERNEST K. ADAMS.

FOUCAULT'S pendulum demonstration of the rotation of the earth, which was first carried out on a large scale in the Pantheon at Paris in 1851, is perhaps one of the most interesting experiments that physics affords, for it demonstrates to the observer the absolute revolution in space of the earth; not that relative motion which one sees when looking at the firmament on a clear night, but a positive turning of the earth in a certain direction with respect to the celestial sphere. The repetition of Foucault's pendulum demonstration in the Pantheon by M. Camille Flammarion, approximately fifty years after the original, has renewed the interest in the same, and has influenced physicists about the world to again carry out the experiment. The pendulum, however, is limited by the fact that in the course of a short time, depending upon the length of the vibrating system, the oscillations cease.

To overcome this disadvantage and thereby provide a means of prolonging the motion of the pendulum, or maintaining the same in constant vibration, are the purposes of the accompanying designs. The sensitiveness of a Foucault pendulum is well known, but it is

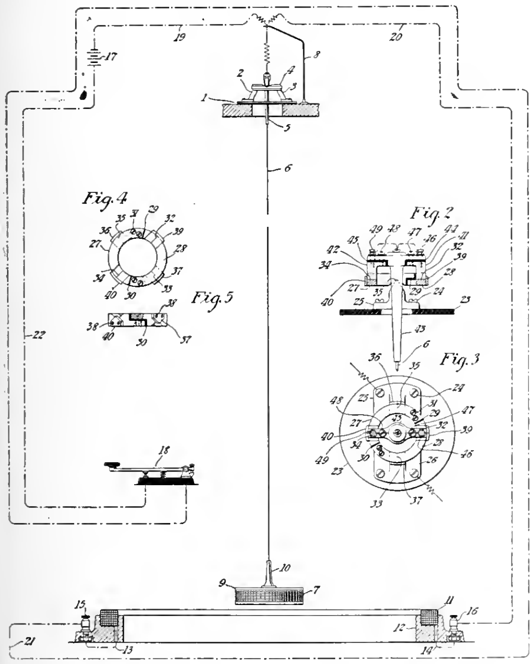

FIG. 1.—KEY-CONTROLLED TYPE OF FOUCAULT PENDULUM.

believed that, under suitable conditions, the acceleration may be satisfactorily accomplished, the present designs being herewith presented, both as suggestions for a line of laboratory investigation in this subject, and as convenient adjuncts in physical lectures or other demonstrations. The accelerating principle of the systems is based upon the electrodynamic action of two coils of different diameters, the smaller of which is incorporated in the bob of the pendulum, while the larger is mounted beneath and symmetrically with respect to the aforesaid pendulum. When direct or alternating currents are allowed to simultaneously flow in the two coils in the same direction, it has been found by experiment that the pendulum coil is urged toward the center of the large coil. This action takes place in whatever plane of oscillation the pendulum coil vibrates, and is strongest when the said coil is directly over a portion of the large coil. In the following designs this principle, which allows of accelerating Foucault pendulums without any material contact therewith, has been incorporated, and a number of methods developed for controlling the accelerating action.

KEY-CONTROLLED TYPE.

In this form of electrical Foucault pendulum, the circuit of the accelerating coils is intended to be manually controlled at a key, which is closed when the pendulum bob is traveling toward the center of the large coil. The frequency with which the key should be closed depends upon the length and weight of the pendulum system, the amplitude of the same, the dimensions of the accelerating coils and the strength of the current employed.

By reference to the drawing, Fig. 1, is a diagram of the system, while Figs. 2 to 5, inclusive, show the details of a modified suspension.

The pendulum system primarily consists of a sensitive knife-edge suspension, which is made up of a base plate, 1, two fixed knife-edges, 2 and 3, rocking ring, 4, and central oscillating member, 5. The base, 1, of the suspension is secured to any support, which is both free from vibration and gives the desired height for swinging the pendulum. Passing through the central member, 5, is a flexible twin concentric conductor, 6, which, secured in the aforesaid member, 5, by tying a knot in it, proceeds downward to the pendulum coil, 7. In order to introduce current into the suspension and yet allow it to vibrate without friction, the twin conductor, 6, is coiled before entering the aforesaid suspension, and, furthermore, suspended above by a small wire standard, 8. The coil, 7, is wound upon a wooden spool, 9. A metal post, 10, bolted to the center of the spool, 9, receives the twin conductor, 6. This conductor, 6, is fastened in the post, 10, by tying a knot in it, or by the employment of some other suitable fastening device. The two wires of the twin conductor, 6, are connected with the terminals of the coil, 7, through suitable openings, which are cut in the spool, 9. Located upon any suitable horizontal surface beneath the pendulum is the stationary coil, 11, which is supported in a wooden mounting, 12. The terminals, 13 and 14, of the coil, 11, are respectively connected to two binding posts, 15 and 16, secured to the mounting, 12. The large coil, 11, is accurately adjusted with respect to the pendulum system, so that the center of the said coil, 11, will be directly under the geometric point of suspension of the pendulum. The adjustment is furthermore so made that the clearance between the spool 9 and coil 11 will be a minimum and constant amount in whatever plane of oscillation the pendulum may vibrate.

The wiring of the system consists in placing the two coils, 7 and 11, in series with a source of current, 17, and controlling key, 18, the circuit being made up, from the aforesaid source, 17, of a wire, 19, one of the members of the twin conductor, 6, pendulum coil, 7, other member of the conductor, 6, wire 20, post 16, conductor 14, stationary coil 11, wire 13, post 15, conductor 21, key 18 and wire 22. As already stated, the current should simultaneously flow in the same direction in the two coils, 7 and 11. Having set the pendulum in vibration in the plane of the meridian by burning a thread in the usual manner, the said thread being tied to any suitable support and the pendulum spool, 9, the pendulum may be maintained in constant vibration, throughout its changing plane of oscillation, by pressing the key, 18, when the pendulum coil, 7, is traveling toward the center of the large coil, 11. In this manner an acceleration may be given to the pendulum without materially interfering with the earth's action upon the same. It will be found that a continual pressing of the key, 18, will hardly be required. On account of the arrangement of the accelerating coils, 7 and 11, of the system, alternating current may be employed for operating the pendulum in place of direct current. It may be found that by suitably proportioning and making the spool, 9, and mounting, 12, of iron, the dynamic action will be increased. In that case, if alternating current is employed, the spool, 9, and mounting, 12, should be divided in one or more places for preventing the induction of heating currents therein.

A modification in the suspension is shown in Figs. 2 to 5, inclusive, whereby current may be introduced to the pendulum coil, 7, without the employment of a coiled wire at the suspension. This device embodies a circular fibre plate, 23, to which is fastened, by a number of screws, 24, two steel knife-edge supports, 25 and 26. Resting upon these knife-edges, 25 and 26, is a rocking ring, made up of two segments, 27 and 28, secured together, but insulated from each other, by two fibre pieces, 29 and 30, screens, 31, together with a number of insulating bushings. Four V-shaped cuts, 32 to 35, inclusive, are made at 90° to each other in the segments, 27 and 28. The two supports, 25 and 26, rest in the cuts, 35 and 33, respectively, and are prevented from sliding therein by two steel stops, 36 and 37, held in position by a number of screws, 38. Resting in the other cuts, 32 and 34, and restricted from longitudinal motion therein by two stops, 39 and 40, are two steel knife-edges, 41 and 42, respectively. The stops, 39 and 40, are held in place, as are the other ones, numbered 36 and 37, by several screws, 38. The knife-edges, 41 and

42, are insulated upon a central rocking member, 43, by two pieces of fibre, 44 and 45, four screws, 46 and 49, inclusive, together with a number of insulating bushings. The twin concentric conductor, 6, which supports the pendulum spool, 9, is knotted in the central member, 43, and the wires of the said conductor, 6, are electrically connected, through the screws, 46 and 49, with the knife-edges, 41 and 42, respectively. It will thus be evident from the construction that current may be led to the pendulum coil, 7, by connecting the controlling circuit with the knife-edge supports, 25 and 26.

HIGH-POTENTIAL TYPE.

The present arrangement is designed to enable a Foucault pendulum organization to be frictionlessly and automatically maintained in vibration throughout its changing plane of oscillation. The accelerating coils of the system possess the same construction and dynamic action as those described in the preceding apparatus. The means, however, of introducing current to the pendulum and stationary coils at the moment that the former is just over the latter, takes advantage of the fact, that, when the secondary circuit of an

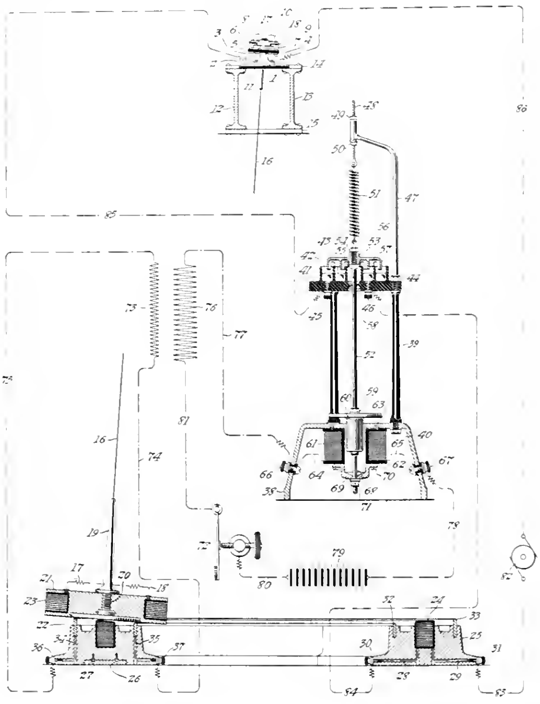

FIG. 2.—HIGH-POTENTIAL TYPE OF FOUCAULT PENDULUM.

induction coil is closed, the current in the primary is immediately augmented. If, now, the primary of the induction coil includes a make-and-break device, suitable battery and sensitive relay, the last of which independently commands the accelerating coils of the pendulum system and a source of current, and, furthermore, the secondary circuit of the induction coil is arranged to be closed by the pendulum with small air-gaps, when the said pendulum is terminating its swing over the stationary coil, the vibrating system will be constantly accelerated in whatever plane of oscillation it may be vibrating, for the temporary closing of the secondary circuit will immediately increase the strength of the primary current, which then instantaneously operates the relay, thereby sending current to the two pendulum coils and giving the system an acceleration. When the pendulum arrives at the other extremity of its amplitude, the same cycle of operations will again take place. The automatic principle of the system is capable of a number of modifications. In the illustration, a diagrammatic view of the organization is shown.

The pendulum system springs from an insulated knife-edge suspension, which, primarily made up of the members 1 to 10, inclusive, and detailed in the preceding description, is rigidly mounted upon a fibre plate, 11, riveted to two iron beams, 12 and 13. These beams, 12 and 13, which are secured together at each end by two metal plates, 14 and 15, may rest upon masonry supports when convenient. A twin concentric conductor, 16, is secured to the central portion, 10, of the suspension, and the two wires, 17 and 18, of the aforesaid conductor, 16, are electrically connected with the knife-edges, 6 and 7, respectively. The lower extremity of the twin conductor, 16, is fastened in a metal post, 19. This post, 19, has an extension, 20, which passes through a wooden spool, 21, and is threaded into a metal disc, 22, let into the under side of the aforesaid spool, 21. The lower ends of the two wires, 17 and 18, of the twin conductor, 16, are electrically joined with the terminals of a coil, 23, which is wound upon the pendulum spool, 21. The stationary accelerating coil, 24, is laid in a circular mounting, 25, which is constructed of wood and made in three sections, fastened together by a number of plates, 26 and screws, 27. The terminals, 28 and 29, of the stationary coil, 24, are, respectively, connected to two binding posts, 30 and 31, which are screwed into the mounting, 25. Incorporated in the mounting, 25, are two split copper rings, 32 and 33, which are employed, in connection with the pendulum disc, 22, for closing the secondary circuit of the induction coil. The rings, 32 and 33, are, respectively, joined by two wires, 34 and 35, with an equal number of binding posts, 36 and 37, secured to the mounting, 25. The reason for dividing the rings, 32 and 33, is so that currents will not be induced therein by the stationary coil, 24. The mounting, 25, is so adjusted with respect to the pendulum system that the center of the said mounting, 25, will be directly beneath the geometric point of suspension of the pendulum conductor, 16. The mounting, 25, is, furthermore, so arranged that it will have a minimum and constant clearance between its upper surface and the under side of the pendulum spool, 21.

The relay for controlling the accelerating circuit of the pendulum system consists of a brass base, 38, to the top of which three hard rubber columns, 39, are secured by an equal number of hexagonal nuts, 40. An ebonite receptacle, 41, having two annular mercury baths, 42 and 43, incorporated in the same, is fastened to the top of the columns, 39, by several hexagonal nuts, 44. Two binding posts, 45 and 46, secured to the receptacle, 41, electrically communicate with the mercury baths, 42 and 43, respectively. Threaded upon one of the columns, 39, is an extension, 47, which has an eye bolt, 48, adjustably secured therein by two hexagonal nuts, 49 and 50. Supported from the eye bolt, 48, by a retractile spring, 51, is a hard rubber rod, 52, having a contact member, 53, fastened thereto by two hexagonal nuts, 54 and 55. This contact member, 53, is provided with two annular projections, 56 and 57, which are adapted to short-circuit the mercury baths, 42 and 43. For enabling the contact to be a multiple one, the projections, 56 and 57, of the member, 53, are toothed. The binding posts, 45 and 46, are placed in series with the accelerating circuit of the pendulum. The rod, 52, is guided at the top by a circular knife-edge, 58, which is turned in the receptacle, 41. At the lower end the rod, 52, is locked by a hexagonal nut, 59, in an iron core, 60, which is adapted to be acted upon by a coil, 61. The spool, 62, upon which the coil, 61, is wound, is fastened to the base, 38, by two screws, 63. The terminals, 64 and 65, of the coil, 61, are, respectively, connected to two binding posts, 66 and 67, which are insulated upon the base, 38, and placed in series with the primary circuit of the already-mentioned induction coil. A spindle, 68, driven into the lower end of the core, 60, is guided by a circular knife-edge, 69, which is fastened to the under side of the spool, 62, by several screws, 70. A nut, 71, is threaded upon the spindle, 68, for limiting the upward motion of the core, 60, due to the retractile spring, 51. The retractile spring, 51, is so chosen and the eye bolt, 48, so adjusted, that the weight of the vertically-moving members will be taken up and the nut, 71, normally maintained against the under side of the knife-edge, 69. When, however, the current in the coil, 61, increases sufficiently to attract the core, 60, the toothed annular projections, 56 and 57, of the contact member, 53, will short-circuit the mercury contacts, 42 and 43.

The operation of the system, presupposing both that the pendulum has been started vibrating in the plane of the meridian, by burning a thread in the customary manner, and the vibrator, 72, of the induction coil, already referred to, has been set in motion, consists, when the pendulum spool, 21, is directly over the stationary coil, 24, of the passage of a number of sparks between the rings, 32 and 33, by way of the copper disc, 22. The secondary circuit of the induction coil is now closed. This circuit is composed of the secondary winding, 73, wire 74, binding post 37, conductor 35, ring 32, disc 22, ring 33, wire 34, binding post 36 and conductor 75. Simultaneously with this flow of current through the secondary, the current in the primary circuit, which is made up of the primary winding, 76, wire 77, binding post 66, conductor 64, relay coil 61, wire 65, binding post 67, conductor 78, battery 79, wire 80, vibrator 72, and conductor 81, will be immediately increased and the relay coil, 61, energized sufficiently to attract its armature, 60. At this moment the projections, 56 and 57, of the contact member, 53, having been moved down into contact with the mercury baths, 42 and 43, a direct or alternating current from a dynamo, 82, is allowed to flow through the accelerating circuit, thereby producing a repulsion between the pendulum and stationary coils, 23 and 24, respectively, and accelerating the pendulum system. This accelerating circuit consists from the dynamo, 82, of a wire, 83, binding post 31, conductor 29, stationary coil 24, wire 28, binding post 30, conductor 84, binding post 46, mercury bath 43, annular projections 56 and 57 of contact member 53, mercury bath 42, binding post 45, wire 85, knife-edge support 2, segment 3 of rocking ring, knife-edge 6, conductor 17, pendulum coil 23, wire 18, knife-edge 7, segment 4, knife-edge support 1 and conductor 86. As soon as the pendulum coil, 23, has swung toward the center sufficiently for the secondary circuit to be broken, the current in the primary will drop to a minimum, and the contact member, 53, of the relay now being allowed to return to its normal position, the circuit of the accelerating coils, 23 and 24, will be interrupted. When the pendulum spool, 21, arrives at the other extremity of its vibration, the same action will again occur, thereby accelerating the pendulum system once more.

The high-potential principle above employed may possibly be further extended in conjunction with the laws of induction, in such a way that the pendulum will consist of a single steel wire. Such a pendulum system may embody a high-potential transformer, the primary of which, together with a large circular stationary accelerating winding, is in series with a source of alternating current. The secondary of the transformer is placed in series with a spark-gap device, which will allow the said secondary to be closed when the pendulum bob is over a portion of the stationary winding, the spark-gap arrangement being such as to render the primary and secondary circuits absolutely independent. The pendulum bob is provided with a short-circuited winding, and the stationary winding is so constructed that, when alternating currents flow in the same, similar alternating currents will be induced in the pendulum winding, when the said winding is directly over a portion of the stationary winding. The pendulum and stationary windings are furthermore so arranged that the directions of the induced currents in the pendulum winding will cause the pendulum to be accelerated toward the center. This method of connecting up the transformer is such that there will be little or no current in the primary coil and stationary winding, until the secondary is closed through the spark-gap device by the pendulum terminating its swing over the aforesaid stationary winding. When this takes place the current in the primary will instantaneously reach a maximum, thereby inducing repulsion currents in the pendulum winding, with a consequent acceleration of the vibrating system. When the secondary is broken the accelerating current will drop to a minimum again until the pendulum arrives at the other side of the stationary winding, at which time the same cycle of operations will be once more performed.

The method of inducing currents in the pendulum coil, with the advantage that a fine steel wire may support the bob of the vibrating pendulum system, may be perhaps arranged in such a way that the stationary winding will be of approximately the same dimensions as the pendulum winding, and located directly under the pendulum suspension. The wiring of the transformer is the same as above outlined, and the action of the spark-gap device, together with the inducing and induced currents, is so planned that a repulsion will occur between the pendulum and stationary windings after the vibrating system has passed the vertical.

SYNCHRONOUS TYPE.

A further method is herewith shown for automatically accelerating Foucault pendulums of any size, however their planes of oscillation may change, there being no material contact with their vibrating systems. The magnetic coils of the system are analogous in their construction and dynamic action to those employed in the preceding studies. The automatic means of operating the pendulum system, however, consists in providing a controlling contact mechanism, which, adjusted in synchronism with the Foucault pendulum, or the latter regulated with respect to the former, sends impulses of current to the pendulum and stationary coils of the organization, when the pendulum of the same is moving toward the center of the stationary coil. In this manner the Foucault pendulum is constantly accelerated. There is, furthermore, herein illustrated a magnetic starting device for the pendulum, thereby obviating the necessity of employing the customary arrangement, where a thread, which holds the pendulum at one of the extremities of its swing, is burned.

By reference to the drawings, Fig. 1, is a diagrammatic scheme of the pendulum system, Fig. 2, a front elevation of the mechanism for controlling the pendulum, and Fig. 3 a detail of the differential gear adjustment for the contact wheel.

The Foucault pendulum primarily embodies a suspension system, which consists of two iron beams, 1 and 2, metal plate 3, fibre base 4, posts 5 and 6, cone-shaped capstan screws, 7 and 8, insulated rocking ring, made up of the two portions 9 and 10, insulated capstan screws 11 and 12, bridge member 13, tube 14, hexagonal nut 15

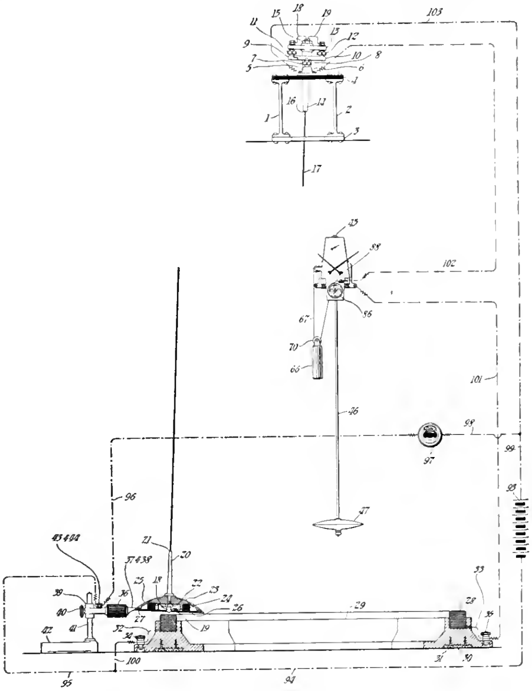

FIG. 3.—SYNCHRONOUS TYPE OF FOUCAULT PENDULUM.

and fibre lining 16. A small twin concentric pendulum conductor, 17, passes through the fibre lining, 16, of the suspension tube, 14, and is held in place by tying a knot in it. The wire, 18 and 19, of the twin conductor, 17, are connected with the insulated capstan screws, 11 and 12, respectively. The lower end of the conductor, 17, is fastened in a pendulum bob, which is made up of a metal post, 20, fibre lining 21, hexagonal nut 22, wooden spool 23, pendulum coil 24, iron rim 25, fibre disc 26 and a number of screws 27. The wires, 18 and 19, of the twin conductor, 17, are electrically joined with the terminals of the pendulum coil, 24. The iron ring, 25, the purpose of which will be described hereafter, is radially slotted in a number of places, in order that currents will not be induced therein by the periodic energization of the pendulum coil, 24. This is particularly necessary if alternating current is employed in the pendulum accelerating circuit. The shape of the pendulum bob is such as to displace as little air as possible in its vibration and changing plane of oscillation. This construction also enables the pendulum coil, 24, to swing directly over the stationary coil, 28. This coil, 28, is designed to be laid in a wooden mounting, 29, which, for the sake of convenience, is made in sections and fastened together by a number of plates, 30, and screws, 31. The terminals, 32 and 33, of the stationary coil, 28, are, respectively, connected to two posts, 34 and 35, which are secured to the mounting, 29. The device for starting the pendulum vibrating consists of a magnet, 36, the poles, 37 and 38, of which are adapted to fit the circular iron ring, 25, of the pendulum bob. The cores of the magnet, 36, are provided with a yoke, 39, which is adjustably secured by a knurled screw, 40, upon a vertical rod, 41, driven into the corner of a heavy triangular base, 42. The terminals of the magnet, 36, are connected to two posts, 43 and 44, insulated upon the yoke, 39. By energizing the magnet, 36, which may be adjusted in any desired position, both vertically and horizontally, the pendulum may be held stationary, preparatory to setting it in vibration in the plane of the meridian. To start the pendulum all that is required is to interrupt the current in the magnet, 36.

The controlling contact mechanism, for providing periodic currents for accelerating the pendulum system, is shown in Fig. 1 and detailed in Figs. 2 and 3. This device consists of a second's pendulum movement, primarily embodying a cast-iron bracket, 45, pendulum 46, elliptical bob 47, frame plates 48 and 49, separating posts 50, together with the fastening members 51 and 52. Mounted between the frame plates 48 and 49 is an escapement train, having a ratio of 1 : 720, and made up of a barrel, 53, ratchets, 54 and 55, pawls 56 and 57, gears 58, 59 and 60, pinions 61, 62 and 63, thirty-toothed escapement wheel 64, and anchor 65. The barrel, 53, is operated by a weight, 66, through the medium of a cord, 67, which is wound about the aforesaid barrel, 53, and secured to a post, 68, driven into the front frame plate, 49. A pulley, 69, journaled upon the frame plate, 49, guides the cord, 67, from the barrel, 53, to a second pulley, 70, mounted upon the weight, 66. With an ordinary drop for the weight, 66, the ratios are such as to drive the pendulum, 46, for eight days. A second gear train, having a ratio of 1 : 720, is also driven by the barrel, 53, the members of the said train being numbered 71 to 75, inclusive. The terminating spindle, 76, of this

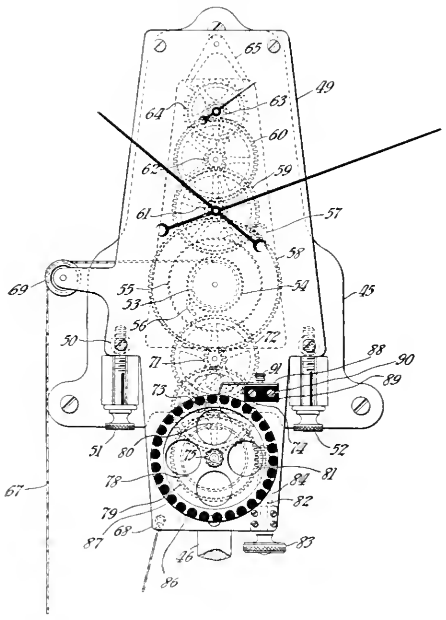

FIG. 4.—CONTACT MECHANISM OF SYNCHRONOUS TYPE.

second train has mounted thereon a differential gear adjustment, which consists of two crown gears, 77 and 78, intermediate worm gear 79, plantetary pinion 80, worm 81, spindle 82, knurled adjustment member 83, and journaling portion 84. The crown gear, 78, is secured to a sleeve, 85, which, mounted loosely upon the spindle, 76, passes through the frame plate, 49, and has secured thereto a contact wheel, 86, having a number of fibre rods, 87, let into its periphery. The circumference of the contact wheel, 86, is turned down sufficiently to make the insulating and metallic spaces equal in width. Bearing upon the contact wheel, 86, which, on account of the gearing, makes one turn per minute in an anti-clockwise direction from the front, is a platinum-pointed spring, 88, mounted upon the frame plate, 49, by a fibre block, 89, together with several screws, 90 and 91. From the property of the differential adjustment, when the worm, 81, is revolved by turning the knurled member, 83, the contact wheel, 86, may be adjusted, while running, until the impulses of current, which are sent to the pendulum accelerating coils, 24 and 28, are in proper step with the vibrations of the Foucault pendulum system. When desired a dial, 92, may be mounted upon the frame plate, 49, of the movement, an opening being provided in the said dial, 92, for the contact spring, 88, to pass therethrough.

For enabling the mechanism to control pendulums of different lengths, it is intended that a number of contact wheels, similar to that numbered 86, but having varying numbers of insulated rods driven into their peripheries, shall be employed. Thus, if the Foucault pendulum makes one beat per second, the electrical contact, while the pendulum coil, 24, is traveling toward the center of the

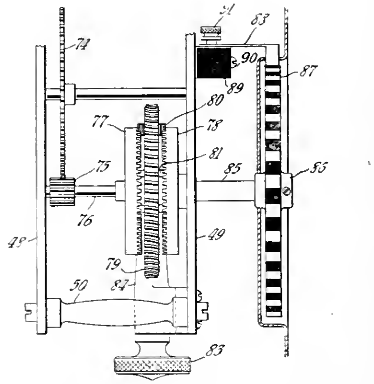

FIG. 5.—CONTACT ADJUSTMENT OF SYNCHRONOUS TYPE.

stationary coil, 28, should last .5 second, and there will be sixty contacts, together with an equal number of insulating spaces upon the periphery of the contact wheel. For a pendulum having a beat of 1.5 seconds, the contact should last .75 second, and there will be forty fibre rods in the contact wheel. If the pendulum makes a vibration in two seconds, the electrical contact will have a duration of one second, and there will be thirty fibre rods in the contact wheel. With a beat of 2.5 seconds for the pendulum, the contact will last 1.25 second, and there will be twenty-four fibre rods in the contact wheel. For a pendulum making as oscillation in 5 seconds, the contact will last 2.5 seconds, and the contact wheel should have twelve fibre segments. With a pendulum making a vibration in 7.5 seconds, the contact should last 3.75 seconds, and there will be eight insulating rods in the periphery of the contact wheel. By being able to substitute different contact wheels, the controlling mechanism may be adapted to a Foucault pendulum of any given length.

Having set up the pendulum system in an enclosure, if possible similar to the dome of the Pantheon in Paris or other like structure, the pendulum bob is held at one of the extremities of its amplitude by energizing the magnet, 36, of the starting device, the circuit consisting from a battery, 93, or other suitable source of current, of two conductors, 94 and 95, binding post, 43, coils of magnet, 36, post 44, wire 96, switch 97, together with the conductors 98 and 99. When it is desired to start the Foucault pendulum, the switch, 97, is opened, and, the magnet, 36, being now without attractive force, the pendulum will begin to vibrate. The knurled member, 83, of the controlling mechanism is then adjusted until the impulses of current, sent out therefrom to the pendulum coils, 24 and 28, always occur while the pendulum is traveling toward the center of the large coil, 28. The circuit for producing this constant acceleration embodies the battery, 93, conductors, 94 and 100, post 34, wire 32, stationary coil 28, conductor 33, post 35, wire 101, frame 45 of controlling movement, contact wheel 86, spring 88, conductor 102, post 5, capstan screw 7, portion 10 of rocking ring, capstan screw 12, wire 19 of pendulum twin conductor 17, coil 24, wire 18, capstan screw 11, portion 9 of rocking ring, capstan screw 8, post 6, together with the conductors 103 and 99. In setting up the system, the length of the Foucault and current-controlling pendulums, together with the contact wheel, should be so chosen and adjusted that the occurrences of the accelerating current will be in synchronism with the oscillations of the aforesaid Foucault pendulum. The general principle of the organization is also applicable to time service systems.

In the above series of electrically-operated Foucault pendulums, current has been simultaneously sent through the pendulum accelerating coils in the same direction, thereby causing the pendulum coil to be accelerated toward the center of the stationary coil. It is believed that the reverse action may be also employed for operating Foucault pendulums. In this case, current is allowed to flow at the same instant in opposite directions in the two accelerating coils, the pendulum being radially accelerated away from the center of the stationary coil.

For measuring the angular change of the plane of oscillation of Foucault pendulums, other devices may be employed, irrespective of the customary method where a fine needle, which is affixed to the bottom of the pendulum bob, is allowed to travel over a graduated circle or make small furrows through the top of a pointed heap of sand. When the length of the pendulum is suitable, and the facilities are favorable therefor, the angular variation may be observed from a point just below the suspension. The arrangement for this purpose may consist of a graduated ring, which is rotatively secured to a suitable horizontal mounting, the pendulum occupying the center of the aforesaid ring. A fine wire is attached to opposite points of the ring, and passes within a short distance of the pendulum. An index is provided upon the mounting adjacent to the graduations upon the ring. Having turned the ring until the wire is coincident with the plane of oscillation of the pendulum bob below, the angular change may be observed, at the end of any given period of measurement, by again revolving the ring until the wire is in coincidence with the pendulum's path. This operation may be facilitated by suitably mounting a telescope upon the graduated ring, and providing a highly polished point in the center of the pendulum bob to sight upon. Another method may embody a carriage which is adapted to slide around a graduated ring, mounted symmetrically at the bottom of the pendulum system. Passing radially through the carriage is a pointed rod, which may be moved up to the pendulum wire, when the same is resting in its normal vertical position or at the end of its maximum amplitude. Having once set the rod in the plane of vibration of the pendulum, the angular change may be noted at any time by circumferentially moving the carriage until the rod is again in coincidence with the pendulum's plane. When desired, the mounting of the stationary accelerating winding of the pendulum system may be arranged to receive the above-mentioned sliding carriage.

The Theoretical Determination of Power Curves.

By WILLIAM J. BERRY.

THE close relation existing between practical electrical engineering and the higher mathematics is daily receiving wider and wider recognition from engineers of established reputation, while the fact that many mathematical theorems find their best illustrations in electrical phenomena is well known to all who have pursued mathematical investigations to any considerable extent. The time has passed when the practical rule-of-thumb electrician could afford to sneer at the mathematical engineer, because of the latter's theorising; empiricism has carried the profession as far as it can, henceforth the advance must be along the strictest scientific and theoretic lines. Many facts, revealed by experimental investigation, and made familiar through long-continued practice, are demonstrable from the standpoint of the mathematician.

One such subject is that of power curves. Every alternating-current engineer knows that with an impressed harmonic e.m.f. of sine-wave shape, the resultant power curve is a sine curve of double frequency, but so far as the present writer knows there exists no rigid mathematical demonstration of this fact. Messrs. Ryan, Norris and Hoxie, in their recently-published book, have proved it for certain special values of the angle of lag, but the demonstration which follows is valid for any amount of phase difference, whether the current leads or lags behind the e.m.f.

Let the curve, E, in Fig. 1, represent a pressure curve of sine-wave shape, and suppose its equation to be $y = A \sin x$, where A is a constant; let I, in the same figure, be the current curve, differing in phase from E by the angle ϕ, and let $y' = B \sin [x \pm \phi]$ represent its equation, in which B is a constant, and the plus or minus sign is to be used, according as ϕ is the amount of lag or lead of the current. Since the instantaneous power is equal to the product of the instantaneous pressure by the instantaneous current, the ordinates of the power curve, P, must be the product of the correspond-

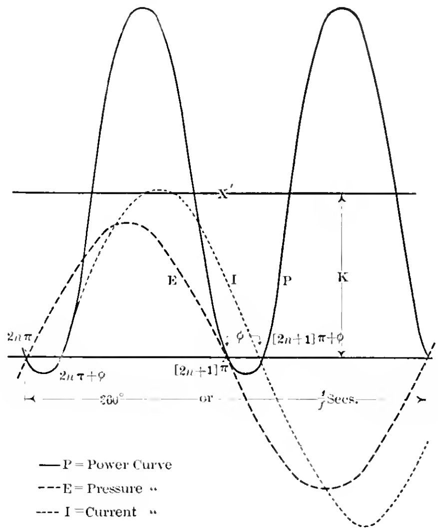

FIG. 1.—PRESSURE CURVE.

ing ordinates of E and I, and the equation of P is $y'' = y\,y' = A\,B \sin x \sin [x \pm \phi]$.

Expanding this expression, and replacing $A\,B$ by C,

$$y'' = C\,[\sin^2 x \cos \phi \pm \sin x \cos x \cos \phi].$$

Now, in any given case ϕ, and, therefore, $\sin \phi$ and $\cos \phi$ are constant throughout, hence

$$y'' = C\,[\alpha \sin^2 x \pm \beta \sin x \cos x],$$

where

$$\alpha = \cos \phi \text{ and } \beta = \sin \phi.$$

This may be further simplified,

$$y'' = \alpha' \sin^2 x \pm \beta' \sin x \cos x,$$

where

$$\alpha' = C\,\alpha, \text{ and } \beta' = C\,\beta.$$

$$y'' = \alpha' \sin^2 x \pm \frac{\beta'}{2}\, 2 \sin x \cos x,$$

$$y'' = \alpha' \sin^2 x \pm \frac{\beta'}{2} \sin 2x.$$

Differentiating with respect to x,

$$D_x\, y'' = 2\,\alpha' \sin x \cos x\, d\,x \pm \frac{\beta'}{2} \cos 2\,x\,.\,2\,d\,x,$$

$$D_x\, y'' = \frac{\alpha'}{2} \sin 2\,x\,.\,2\,d\,x \pm \frac{\beta'}{2} \cos 2\,x\,.\,2\,d\,x.$$

Integrating,

$y'' = -\frac{\alpha'}{2} \cos 2\,x \pm \frac{\beta'}{2} \sin 2\,x + K$, where K is the constant of integration. If, now, we replace $\frac{\alpha'}{2}$ by $C' \cos \phi$, and $\frac{\beta'}{2}$ by $C' \sin \phi$, where $C' = -\frac{C}{2}$, the equation reduces to

$$y'' = C'\,[\cos' 2\,x \cos \phi \mp \sin 2\,x \sin \phi] + K.$$

To eliminate the constant, K, we may transform the equation to a parallel X-axis, such that y''', the new ordinate of P, is equal to $y'' - K$, whence

$$y''' = C' \,[\, \cos' 2x \cos \phi \mp \sin 2x \sin \phi].$$

The significance of this transformation of co-ordinates will be explained later. But

$$y''' = \frac{C'}{2}\,[2 \cos 2x \cos \phi] \pm \frac{C'}{2}\,[-2 \sin 2x \sin \phi].$$

$$2 \cos 2x \cos \phi = \cos\,[2x + \phi] + \cos\,[2x - \phi],$$

and

$$-2 \sin 2x \sin \phi = \cos\,[2x + \phi] - \cos\,[2x - \phi].$$

(See Wentworth's Trig., § 31, or Murray's Trig., § 52.) Hence,

$$y''' = C' \cos\,[2x \pm \phi] = C' \sin\,[\frac{\pi}{2} - (2x \pm \phi)],$$

which proves that under the given conditions, the power curve is a sine curve.

Now, the number of lobes of the curve per cycle is equal to the number of roots per cycle; that is, to the number of times the curve cuts the X-axis. The pressure curve, E, or $y = A \sin x$, has roots, that is, $y = 0$, whenever $\sin x = 0$, since by hypothesis A cannot be zero; but $\sin x = 0$ for $x = 2n\pi$, or $[2n + 1]\pi$; that is, twice in one cycle, or twice during the interval $1/f$ secs., where f is the number of cycles per second.

Similarly, $y' = B \sin\,[x \pm \phi]$, the current curve, has roots whenever $[x \pm \phi] = 2n\pi$, or $[2n + 1]\pi$, and this occurs twice during the interval $1/f$ seconds.

But the power curve, P, being of the form $A B \sin x \sin\,[x \pm \phi]$, will have roots whenever either $\sin x = 0$, or $\sin\,[x \pm \phi] = 0$. P, therefore, cuts the X-axis at $x = 2n\pi$, $x = [2n + 1]\pi$, $x = \mp \phi 2n\pi$, $x = [2n + 1]\pi \mp \phi$, or four times during the interval $1/f$ seconds; which shows that the power curve has double the frequency of either the e.m.f. or current curves, and that this is totally independent of phase difference.

By referring to Fig. 1, it will be noticed that X, the axis of symmetry of E and I, is not the axis of symmetry for P, but that X', parallel to X, is such an axis. When in the foregoing discussion we transformed the equation from one set of co-ordinates to another

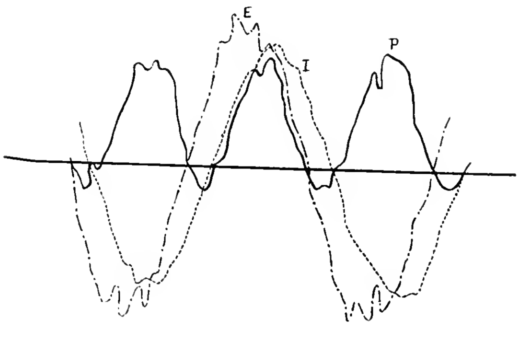

FIG. 2.—CURVES.

in such manner as to eliminate the constant, K, we were really transferring from X to X', the constant of integration, K representing the distance between X and X'.

In Fig. 2 is given a set of curves obtained by the writer and his associates, from a ½-kw Westinghouse alternator in the laboratory of the Polytechnic Institute of Brooklyn, the alternator carrying an inductive load. Though only approximating the sine shape, this power curve illustrates the main points discussed in this article. The ordinates of the power curve in Fig. 2 have been multiplied by a reduction factor, to bring the curve within the limits of the cross-section paper employed in the original, of which this figure is a tracing.

Sports in Aid of Spanish War Veterans.

The Spanish War Veterans' organization, which is about to conduct athletic sports in this city, is composed of veterans of the Spanish war who were honorably discharged or mustered out. The association is similar to and modeled upon the Grand Army of the Republic. Many comrades are at times in needy circumstances and require financial assistance. The widows and children of deceased comrades frequently require help and funds are needed to defray the burial expenses of comrades who die in poverty. These are worthy charities which appeal to all who honor these men who fought for their country in the Spanish war. The treasuries of the corps and individual commands, replenished only by per capita taxes, are insufficient. Funds disbursed by the Spanish War Veterans' Associations for such purposes are disbursed under scrupulous supervision and only in the most worthy cases.

General Eugene Griffin is corps commander of the State of New York Spanish War Veterans, which comprises about thirty-five commands and nearly 5,000 enrolled comrades. The commands in the vicinity of New York City (about twenty) have arranged to hold a military athletic tournament in the armory of the Twenty-second Regiment, N. G. S. N. Y., on March 5, 1904, the net proceeds to go to the treasuries of the corps and commands concerned. In order that the tournament may be held under the auspices and with the sanction of the Amateur Athletic Union, it has been necessary for the commands to organize the Spanish War Veterans' Athletic Association, and the tournament will be held in the name of such association.

Great interest has been manifested in the project. The use of the armory has been donated, and the services of all concerned in the tournament (other than the professionals, such as starter, handicapper, etc.) have been and will be given free. The tournament will be the athletic event of the winter.

The prizes will have sentimental as well as intrinsic value. President Roosevelt has donated funds for the purchase of a prize. Admiral Dewey has donated a cup with a personal letter, suggesting that the cup be offered as the "Dewey Cup." Cups have also been donated by Hon. Elihu Root, Secretary of War; Gen. Robert Shaw Oliver, Assistant Secretary of War; Gen. Geo. L. Gillespie, Chief of Engineers; Gen. Wm. Crozier, Chief of Ordnance; Col. John Jacob Astor, Senator Depew, Senator Platt, Senator Proctor, Senator Hanna, Senator Alger, Senator Lodge, Hon. Geo. B. McClellan, Hon. Wm. Randolph Hearst.

It is expected that other prizes will be offered by prominent officials of the Army and Navy, by Senators and Representatives of the United States Congress and by governors of States. The interest in the tournament, the number of athletic entries and the attendance will be greatly increased by the desire to win cups presented by such donors. Subscriptions from those interested should be paid to Gen. Eugene Griffin, at 44 Broad Street, New York City, for the prize fund of the tournament to be held for the benefit of the Spanish war veterans, as above described.

Philadelphia A. I. E. E. Meeting.

The regular meeting of the Philadelphia Branch of the American Institute of Electrical Engineers was held January 11 at the Engineers' Club. Mr. W. C. L. Eglin discussed the paper presented by Mr. George H. Lukes at the New York meeting on "Overhead High-Tension Distributing Systems in Suburban Districts." He also presented his own paper on "Safeguards and Regulations in Operation of Overhead Distributing System," with considerable amplification. Mr. J. T. Hutchings, of the Philadelphia Electric Company, presented a paper, using Mr. E. J. Bechtel's paper on "Automatic Apparatus for Regulating Generator and Feeder Potentials" as a basis, and going somewhat further into the matter than Mr. Bechtel did. Mr. J. B. Klumpp, of the United Gas Improvement Company, of Philadelphia, presented a paper, discussing and criticising the paper on "Gas Power for Central Stations," read by Mr. J. R. Bibbins at New York. The discussion of these papers was participated in by Messrs. Paul Spencer, W. C. L. Eglin, C. W. Pike, Charles Hewitt, H. A. Foster, J. B. Klumpp and Carl Hering.

The Gilbert Tercentenary Picture.

Some details were recently given in these pages of the presentation of a picture to the corporation of Colchester, England, by the Institution of Electrical Engineers, to celebrate the three-hundredth anniversary of the death of Dr. Gilbert, December 10. We are now glad to be able to publish herewith a reproduction of the historical painting in question. The artist is Mr. A. Ackland Hunt, and the original picture measures about 6 ft. x 4 ft. Its cost was defrayed by private subscription and the picture, it appears, was exhibited originally at the Manchester Exhibition in 1876. Prof. Silvanus P. Thompson and Mr. Conrad W. Cooke acted as honorary secretaries of the fund and the contributions were given by past and present members of the council of the Institution. As will be seen, it is an interesting and vigorous piece of work, and it is considered by students of the period, such as Prof. Thompson, a faithful piece of portraiture as well as a happy piece of imagination as to just what might have occurred when Gilbert made an exhibition before Queen Elizabeth of some of his experiments and investigations.

THE ACKLAND HUNT PICTURE OF DR. GILBERT MAKING EXPERIMENTS BEFORE QUEEN ELIZABETH.

Gilbert was born in the town in which he died and spent the best part of his life there, aside from the time given to the practice of his profession in London. It may be noted that Gilbert was born at Colchester on May 25, 1544, in a house which is still standing, and to which he returned in his later years. It may be added that Dr. Gilbert, as physician to Queen Elizabeth and president of the Royal College of Physicians, was one who would naturally stand high in her favor and whose demonstrations as thus depicted would be witnessed by the Virgin Queen with unusual interest.

There are not many historical pictures on electrical subjects and this makes a worthy addition to that which is doubtless well known to our readers, of Volta explaining his voltaic pile to young Napoleon, and the other one, perhaps better known in this country than abroad, of the gathering of the pioneers of the first Atlantic cable, now hanging in the New York Chamber of Commerce. Some day, perhaps, in the new Union Engineering Building, the American Institute of Electrical Engineers may become the recipient of other works of this character from generous friends and members. To-day the Institute is even without a picture or a bust of Franklin.

Electrification of an English Steam Railway.

The Lancashire & Yorkshire Railway Company, one of the most important of the shorter steam railroads in England, has substituted electricity for steam as motive power, and the electrical operation of a portion of the line was recently inaugurated. The 600-volt direct-current rotary-converter system is used, with alternating-current transmission to the converter sub-stations at 7,500 volts. The line is 23 miles long and double-tracked.

The trains generally are composed of two first and two third-class cars, the third-class cars of which are equipped with four motors of 150 hp each, making a total of 1,200 hp per train. To operate these motors current is obtained from a third rail, which is fed with direct current at about 600 volts from four sub-stations, three of which are situated at Birkdale, Seaforth and Sandhills, respectively, and another in the main power house building at Formby.

The power station adjoins the railway, on the banks of the River Alt, at Formby, and is a building 290 feet long by 130 feet wide, consisting of an independent steel structure, the steel stanchions of which, in addition to carrying the roof, support traveling cranes over the engine room, the spaces between the stanchions being filled with brickwork. It has two spans, one containing sixteen Lancashire boilers, 8 feet 6 inches in diameter, by 32 feet long, for a working pressure of 160 pounds per square inch, together with superheaters, feed pumps, induced draught plant, etc.; the other and larger span contains four horizontal cross-compound condensing engines of 1,500-kw capacity, also one subsidiary vertical compound condensing engine of 750-kw capacity, capable of taking large overload for short periods.

The generators in connection with these engines are of the three-phase type, with a periodicity of 25, and a voltage of 7,500. The engine room also contains steam-driven exciters, sub-station plant and a main switchboard.

Three-core paper-insulated metallic-sheathed cables convey the high-tension current to the sub-stations, and are laid on what is known as the "solid system," at a suitable depth along the company's right of way.

The sub-station equipments, similar in character, consist of transformers, which step-down the three-phase alternating current of 7,500 volts to low-tension alternating current, from which it is converted in rotary converters to direct current at 600 volts. The rotary converters are nominally of 600-kw capacity, four being provided in each sub-station, and three static transformers, cooled by means of air blast, are provided in connection with each rotary. The connections from these sub-stations to the third rail are made by insulated copper cables, run underground in troughing.

The third rail is carried outside the track rails, and is supported

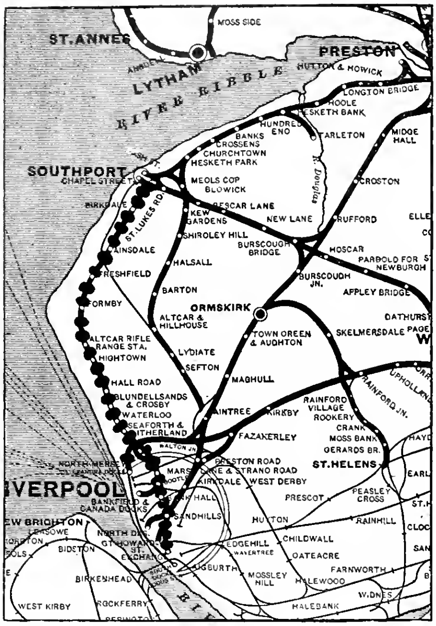

FIG. 1.—MAP OF ROUTE.

at intervals of 10 feet on insulators. The center of the rail is 3 feet $11\frac{1}{2}$ inches from the center line of the track, and the top of the rail 3 inches above the surface of the track rails, these being limensions agreed upon between all the British railway companies.

The third rail, which is of special composition to secure conductivity, weighs 70 pounds per yard, and is protected by a timber guard rail at points where there might be danger of accidental contact. To insure a good return circuit a fourth rail, supported on wooden blocks, has been placed in the 4-foot way, and bonded to each running rail; this method of return, it was thought, would interfere least with the running tracks, and would permit the easy removal of any running rail at any time.

FIG. 2.—ELECTRIC TRAIN ON LANCASHIRE & YORKSHIRE RAILWAY.

The cars differ from those used on the steam lines of the company, and were built especially for the service. They are 60 feet long and 10 feet wide, being the widest cars in Great Britain. This width was adopted because it was found before any operations were begun that it was possible on the Southport line, as distinguished from other parts of the main line, to have wider stock, some slight alterations to the track and some trifling ones to the platforms along this length alone being necessary. The carriages have center aisles throughout, with vestibules to allow passage from one carriage to the next, this arrangement being borrowed from American practice.

The motor cars are at the ends of the train, and are the third-class cars, and, as previously described, are equipped with two 150-hp motors on each truck, and with multiple-unit control. The front end has a small compartment for the motorman, containing all the apparatus for controlling the train; and near this is a baggage compartment, the remainder of the car being devoted to passengers. Most of the seats are cross-seats, and seat three on one side of the passage and two on the other, but at the ends are longitudinal, to allow more room for passengers entering or leaving the cars. The trailers or first-class cars have seats arranged after the same design, but only two on each side of the passage. A four-car train will carry 270 passengers, the third class seating 69 and the first-class 66 people. The delay at stations will be reduced to the smallest possible amount. Notice boards are hung on the platforms showing passengers where to stand to await their class, and in order to ensure quick loading and unloading of passengers, strict regulations are made that every passenger is to enter the cars at the end door and leave by the front door, thus ensuring a continuous circulation.

In view of the alarm caused within recent months by fires on electric trains, the company has taken all possible precaution against such an occurrence. The motor compartments have, with the exception of the roof, which is covered with sheet-steel plates, been lined with uralite, a well-known fireproof material, the floor also being fireproof. In addition, the cable conduits are lined with uralite, and the whole of the floor over the motors is covered with the same material and thin steel plates. All the trains also carry fire appliances.

The vacuum brake used on the trains is, with some slight differences, the same as that used all over the Lancashire & Yorkshire Railway. It is fitted with quick-acting valves, but is provided with an electrical exhauster in place of the steam ejector on the locomotive.

The service will start with a 10 minutes headway in both directions between Liverpool and Hall Road, and every second train will run through to Southport. In addition an hourly express will run in each direction between Liverpool and Southport, and at certain times the trains arriving at Southport from Liverpool will go on to Crossens. The accommodation trains between Liverpool and Hall Road and those between Liverpool and Southport will be run in less time than at present, but it is not intended that the expresses to Southport shall do the journey in less time than the fastest steam trains now running.

The whole of the work with the exception of the rolling stock, which is being made at the Horwich and Newton Heath Works of the railway company, is being carried out by Dick, Kerr & Company, Ltd., of London and Preston, who are now completing at their Preston works the main and auxiliary generators, the sub-station equipment, the control equipments of the trains and the rest of the electrical plant.

Automobile School.

The Boston Y. M. C. A. inaugurated an automobile school last fall. The course embraces practical as well as theoretical study and instruction as to automobiles. This is claimed to be the first automobile school established in the world, and, according to a recent report, it has been very successful so far.

International Electrical Congress of St. Louis.

According to the present indications, the International Electrical Congress, to be in session at St. Louis, September 12-17, 1904, will be one of the most successful that has yet been held, both with respect to the number of adhesions and to the value of the transactions.

Up to date about 3,550 circular letters of invitations to join the Congress have been issued to persons or associations in North America. From these 875 postcard acceptances of membership have been received. About 350 similar circular letters of invitation have been recently sent to other countries. It is intended to issue in all about 5,000 invitation circular letters in America and about 6,000 in foreign countries. It is expected that many persons will join the Congress, both in America and abroad, who do not expect to attend the sessions in St. Louis, in order to secure a copy of the Transactions, which will form one and perhaps two large octavo volumes. Collection of fees has commenced, and upon receipt of a fee the member will be forwarded a certificate of membership. The certificate is 8½ in. by 11 in. in size (21.5 cm. x 28 cm.) and printed on heavy paper of excellent quality. A miniature replica of this certificate, without the signatures, is appended.

Recently 280 special letters of invitation have been issued on behalf of the committee of organization to prominent electricians and electrical engineers, signed by the president and the general secretary of the committee, requesting papers for the Congress in th various sections. Of these 146 have been sent to foreign authors, and 134 to American authors. There has not been time to receive replies from more than a few foreign authors, but 21 acceptances have, up to date, been received from abroad, and 46 acceptances from North America. Sixty-seven papers are thus already promised for the Congress, and the number is steadily increasing. A considerable number of invitations to contribute papers have yet to be issued. It is hoped that the Congress will convene with a full programme in each section, and that at least half of the papers may be from foreign countries. According to the plans of the committee, papers for the Congress programme are specially invited, but papers voluntarily offered will be submitted to the officers of the sections to which the papers belong, and may be included in the programme by invitation at their request, if the subjects are desirable, and if the schedule allotted to each section will permit, it being the desire of the section officers to secure and offer the best possible programme and presentation.

International Electrical Congress

St. Louis. 1904

Henry J. Caldwell

having been invited to participate in the International Electrical Congress of St. Louis, 1904, and having duly paid the fees is hereby enrolled a member with the privilege of attending all general and sectional meetings, and of receiving the printed transactions of the Congress

For Committee of Organization

President Treasurer General Secretary

ELECTRICAL CONGRESS MEMBERSHIP CERTIFICATE.

Petitions from the Congress Committee of Organization, and from the president of the American Institute of Electrical Engineers, have been filed with the Department of State at Washington, through the Department of Commerce and Labor, and the National Bureau of Standards, urging that the various foreign governments should be invited to appoint official delegates to the Congress. The lists of such delegates to be invited is, in accordance with the lists, allotted to the various countries at the Paris Congress of 1900, and the Chicago Congress of 1893. Including the United States, the lists comprise 56 official delegates. Information has been received that these petitions have been granted, and that the State Department on the 17th of December, 1903, instructed the diplomatic officers of the United States abroad to extend an invitation to foreign countries to be represented at the Congress by delegates.

Arrangements are being made with a view to perfecting plans of co-operation between the Congress and electrical societies and associations in various parts of the world. Invitations have already been extended to the Congress members to visit places of electrical interest on the journey to or from St. Louis.

The Committee of Organization of the Congress consists of Elihu Thomson, president; A. E. Kennelly, general secretary; W. D. Weaver, treasurer; Bion J. Arnold, vice-president and chairman of Executive Committee; C. F. Scott, Dr. S. W. Stratton, Prof. H. S. Carhart and Prof. W. E. Goldsborough, vice-presidents.

The following section officers (chairmen and secretaries) have been appointed by the president, and have already done much work in organizing their sections:

Sec. A General Theory,	Prof. E. L. Nichols, Cornell University.	Prof. H. T. Barnes, McGill University.
Sec. B General Applications,	C. P. Steinmetz, Schenectady.	Prof. Samuel Sheldon, Brooklyn.
Sec. C Electrochemistry,	Prof. H. S. Carhart, Univ. of Michigan.	Carl Hering, Philadelphia.
Sec. D Elec. Power Transmission,	Mr. C. F. Scott, Pittsburg.	Dr. Louis Bell, Boston.
Sec. E Electric Light and Distribution,	Mr. J. W. Lieb, Jr., New York.	Mr. G. S. Dunn, New York.
Sec. F Electric Transportation,	Dr. Louis Duncan, Mass. Inst. of Technology.	Mr. A. H. Armstrong, Schenectady.
Sec. G Electric Communication,	Mr. F. W. Jones, New York.	Mr. Bancroft Gherardi, N. Y.
Sec. H Electrotherapeutics,	Dr. W. J. Morton, New York.	Mr. W. J. Jenks, New York.

All communications should be addressed to the General Secretary, Dr. A. E. Kennelly, Harvard University, Cambridge, Mass. He reports general and widespread interest in the subject as indicated by the correspondence, the bulk of which may be faintly inferred from the figures that have been quoted above. Indeed, the interest attaching to the work of the Congress is one of the best of auguries as to its abounding success.

An Automobile Engineers' Society.

Automobile engineers held a meeting last week in the club rooms of the New York Automobile Trade Club and organized the Society of Automobile Engineers, with E. T. Birdsall, of the Standard Automobile Company, in the chair. Those present favored the formation of a body similar to the American Society of Mechanical Engineers in objects and work. The chief mission of the society will be the interchange of technical automobile knowledge among the members. Quarterly meetings will be held and papers will be read on mechanical topics.

These officers were elected: President, A. L. Riker, Locomobile Company of America; first vice-president, Henry Ford, Ford Motor Car Company; second vice-president, John Wilkinson, Franklin Motor Car Company; secretary and treasurer, E. T. Birdsall, Standard Automobile Company. Membership Committee—A. H. Whiting, Edison Battery Company (chairman); A. L. Riker, L. I. Gibbs and E. T. Birdsall.

Nearly fifty applications for membership are in hand. There will be two classes of members, viz., an active class, for registered engineers, and an associate class, for members interested in automobile sale or construction who are not engineers. It is interesting to note the prominence of men of electrical training and connections.

Convention of the Northwestern Electrical Association.

IN our issue of last week a telegraphic report was given of the opening sessions of the convention of the Northwestern Electrical Association. Below we present a fuller account of the proceedings up to the time of adjournment.

Secretary-Treasurer Mercein's report called attention to the resolution adopted last January to hold a summer meeting at St. Louis, in the present year, in connection with the National Electric Light Association. He recommended that the association take action in regard to this. The balance in the treasury, as further reported, showed the finances of the association to be in good condition. Adjournment was then taken until 1.45 the same afternoon.

In the presidential address, Mr. F. W. Bowen called attention to the "Question Box" and "Wrinkle" department, which he had hoped to make a feature of the present convention, but had been prevented from so doing because of much additional work which had been thrown upon him incident to the destruction of his station by fire twice. The programme, however, was prepared with a view to presenting matters which would be of interest to the members, both active and associate. The question of pre-arranged discussion of papers was not considered advisable, as it would not afford the opportunity which otherwise would present itself, and because the ranks of the association include such men and minds as are competent enough to discuss any paper offered in the programme.

Mr. Bowen called attention to the fact that the commercial side of every proposition is the one which most appeals to the central station man. Continuing, he considered that the general principles of the business seem to be better settled and more fully grounded and the lines of machine building seems to have reached an ultimate standard, for a considerable time at least, and, therefore, the central station man is very much nearer a standard than ever before. The twin subjects of "Taxation" and "Municipal Ownership" were touched upon, as well as several other phases of the central station business, which are of vital interest to all.

Letters were then read from various sub-committees of the legislative committee, reporting the progress made in their particular States. The committee on membership then recommended a number of applications. It was deemed advisable to continue the committee on uniform advertising, and Mr. H. Almert was added to the same.

After some discussion a motion was carried that the summer meeting be held in September at St. Louis to meet with the other electrical associations and electrical people, the date to be left to the executive committee. It was also decided to send a representative in the person of the secretary, to the convention of the National Electric Light Association, to be held at Boston in May.

The Northwestern Electrical Association is to be congratulated upon the fortunate selection it has made in the person of its new president, T. F. Grover. Progressive, liberal and well versed in his chosen field, he will prove a most worthy successor to the retiring president, F. W. Bowen. Identified with electrical interests since the electric current was first introduced on a commercial scale, Mr. Grover is at home in the lighting and street railway field. Being vice-president and general manager of the Eastern Wisconsin Railway & Light Company, he is a member not only of the Northwestern Electrical Association, but of the National Electric Light Association, the American Street Railway Association and the American Gas Light Association as well. Although born and brought up in New Jersey and the East, he has been in the Northwest since 1892. He was the superintendent of the former Milwaukee & Wauwatosa Electric Company, which he left in 1896 to go to Fond du Lac, Wis. He acquired an interest in and was vice-president and superintendent of the then Fond du Lac Electric Company, which, under Mr. Grover's guidance, has steadily advanced. Having secured a new electric light, street railway and gas franchise, he then formed the Fond du Lac Railway & Light Company, which later acquired the property of the Gas Light Company. In 1899 he built the street railway system in Fond du Lac, which in the following year was extended to North Fond du Lac. In 1902 the Fond du Lac & Oshkosh Electric Railway Company was incorporated, of which he was the general manager and later its president. This company was subsequently absorbed by the Eastern Wisconsin Railway & Light Company. Mr. Grover takes an active part in the affairs of his city and is identified with various commercial enterprises.

T. F. GROVER,
PRESIDENT NORTHWESTERN ELECTRICAL ASSOCIATION.

HEATING FROM CENTRAL STATIONS.

The first paper presented in the afternoon session was one on "Central Station Heating," by W. H. Schott. To judge by the discussion of which this paper was productive, it was a subject which is of great interest to many of the central station men. Mr. Schott considered various features common to all systems, but the question to be decided upon when a central station plant is considered is, "Which shall We Use, Water or Steam?"

Hot water heating is in operation in a great many cities, some using a single pipe circuit system, others a two-pipe static head system, and still others a two-pipe balance column system. The single-pipe system is adaptable only where there is a limited territory to serve; for large areas a two-pipe system becomes necessary in order to give the system the necessary amount of flexibility required and to furnish a positive circulation. Where the district to be served is compact with large buildings, ranging in height from six to sixteen stories, the situation then becomes a steam-heating one, the steam being supplied at low pressure, which may be obtained either from engines or furnished direct from boilers.

Heating plants utilizing either water or steam are found to be a better investment where exhaust steam is used in furnishing the heat, or at least part of it. Where exhaust steam exists and it is desirable to use it, this can be done more economically in a hot water system than in a steam system, due to the fact that it may be used at atmospheric pressure, and at a pressure represented by a 20-in. vacuum during the milder periods, the circulation being made positive by using a pump as the circulating medium.

In a well-designed water system there is only required from ten to thirty pounds pressure to overcome the pressure due to circulation and friction of mains, the power utilized by the circulation being absorbed in the circulating water, so that it is not lost. With a steam system sufficient pressure must be maintained upon the mains to overcome the friction in the street work and to furnish the necessary circulation to the surface which is to be heated, this pressure ranging from 2 to 20 pounds and even higher, but ordinarily at from 5 to 10 pounds pressure.

In taking up the question of a central station heating plant, the territory to be heated should be carefully examined by some one familiar with its needs and then a plant designed that will give an economical operation, together with a superior service to meet the needs as found. Many franchises granted in the past are accepted by companies that should never have been accepted, due to the fact that the rates prescribed were entirely too low, resulting in disaster to the company. The street work should be installed in the best possible manner known, great care being taken to see that the main is of ample capacity, and the expansion taken care of in a proper manner so as not to throw undue strain on any fitting in the system; the insulation should be of the best so as to reduce street losses to a minimum, the pipe lines should be properly under-drained so as to eliminate the possibility of water logging, and in a steam system great care should be taken in the maintaining of drains.

The radiation required for a building should be based upon the minimum temperature, or say 20° below zero. If sufficient radiation is set to maintain the standard temperature, a company is only called upon to operate 40 per cent. of its maximum as an average during the entire heating season. It is an absolute necessity to adopt some form of regulation, as otherwise a large amount of heat is wasted. Tests made show that a regulator system will save to the central station 40 per cent. of its fuel requirements, which implies that 40 per cent. more business can be carried on a given plant with regulation.

In a well-designed water system during the average temperature of the heating season six to eight pounds of water per square foot of radiation per hour is ample to furnish all the heat required, but when the temperature is 20° below zero twelve to eighteen pounds of water per square foot per hour are necessary, and the plant must have a corresponding capacity. The same conditions practically apply to a steam as to a water plant.

Mr. Schott said that in tests made recently he has found a wider range in a steam than in a water plant. Comparing the tests taken in a building where the radiation set up was up to requirements against one where the radiation was set on a 52 per cent. basis, he found that a change of 34 per cent. in outside temperature varied condensation in the building where radiation was properly set 13.72 per cent. below in the building underset, the same change in outside temperature varying condensation 24.24 per cent.

As to charges for heating a given space, certainly a rate based on cubical contents is entirely wrong. A building, due to its construction and exposures, may vary from two to eight or ten changes of air per hour. These changes govern the amount of heat required to heat the space in question. Necessarily, to heat properly, the radiation must be based upon the maximum number of changes of air that will take place per hour, and as the number of square feet of radiation set governs the operating expenses of a central station, it must in that case be the basis of charge, either on a square foot or on a meter basis.

With the radiation furnished on a square foot basis and without regulation, a price that would justify the company in operating without any restrictions would seem prohibitive, but the application of regulation is practically like a meter service, in not permitting the building to be overheated, but furnishing the necessary heat to maintain 70 or 72°, the temperature usually agreed upon; with consumers securing their heat upon this basis, they are usually much better satisfied than upon a meter basis, and the income of the company per square foot per season should average higher than with a meter basis.

Probably the ideal method of furnishing heat to the consumer from the station standpoint would be through a meter and at the same time give the consumer automatic regulation. The regulator would prevent the building being overheated and insure an even temperature, and at the same time the company would be paid for all heat so supplied.

Mr. Schott presented several charts, showing the regulation obtained in a building without any manipulation of valves. The regulator closes off the circulation from ten to 70 per cent. of the time in each twenty-four hours, depending entirely on the outside temperature and as an average during the heating season will keep the circulation closed off over 40 per cent. of the time.

If a lighting and power company is in a position to furnish heat, in addition to its light and power, it can eliminate a large percentage of the isolated plants, with which they have always to contend. Moreover, a heating plant enables it to fortify its business against municipal ownership and competition. Consequently, in considering the establishment of a plant of this character, there should be considered the advantages to be gained by the operation of a consolidated property, and due credit should be given the heating department for the assistance it renders the lighting department in securing profitable lighting and power business that a company otherwise could not obtain.

In the discussion of Mr. Schott's paper, Mr. Almert asked the yearly cost of coal in a system with a fairly tight boiler and heating plant, heating say 200 or 210 days a year and using coal containing 11,500 to 12,000 B.T.U., costing say $2.25 per ton. Mr. Schott replied that in a test made recently at Purdue University Prof. Goss showed that the cost was 3.8 cents per square foot per season for hot water; the coal tested 10,500 B.T.U., which would put it on a $2.00 per ton basis. "Assuming the same value for the coal, it would cost a fraction under 8 cents per square foot per season. The actual test was 77 pounds of coal per square foot of radiation per season." With a steam proposition, which runs actually 130 pounds per square foot, an estimate can easily be arrived at to determine the cost with regulation. Without regulation, it will run as high as 180 pounds per square foot.

Mr. Kimball said that in Kenosha great difficulty has been met in differentiating between what is properly chargeable to the electric light plant and that chargeable to the heating plant. About 77 pounds of coal are used per square foot of radiation, in addition to the exhaust steam put into the heating system. Mr. Schott added that in the Purdue test everything was not charged against the heating plant. The engines in that case absorbed 7 per cent. of the heat transmitted to them and the pump absorbed 4 per cent. When it came to condensation, the engines tested at 28½ pounds and the pumps 95½ pounds per indicated horse-power per hour, and everything was charged against the heating plant except the actual heat units absorbed by the engines and pumps. The test proved that the difference in favor of regulation is just about 40 per cent. One should get at least 40 per cent. more for heating without regulation than with it. He said that the amount of heat given off governs the amount of coal burned, and the number of degrees drop in water depends upon how the plant is being worked. Some plants will work on as little as 10° or 12° difference, some 15° to 20°, and we have them as high as 30°. The heavier the load on the plant, the greater the drop will be in the water, on an average.

Mr. Kimball added that in some tests that were recently made the return temperature where regulators were not working was greater; more water was being pumped than where the regulators were operating; but as far as 40 per cent. difference in operating is concerned, he did not figure that the gain in economy would be as much. As to distribution losses, Mr. Schott said he had undertaken to arrive at the street losses, but was not quite satisfied; the tests should continue for a week or ten days and an average taken. In reply to a query, Mr. Schott said if at a temperature of 200° not less than 246 heat units will be given off for each square foot of radiating surface. At 170° there will be 170 units and at 160° 155 units; 160° is the average temperature carried throughout the heating season, providing the radiation is figured on that basis. It is another proposition to fix the radiation on a 210° basis so as to take care of the space at 20° below zero. It takes more radiating surface with the circulating water at 160° than at 210°. The drop in temperature, on the ordinary average distance, which is about half a mile, should not exceed two to three degrees as a maximum. The question of drop in the supply is usually figured on the basis that when the pipe line is handling 60 per cent. of its capacity, a change of water should take place within an hour's time. This might be increased, but when a line is working above 60 per cent. capacity, this should not exceed 2°, and it is being done on less than one. For average conditions 30° difference between supply and return at the power house is an average for standard practice. The difference in the temperature between the supply and return going in and out of a house should not exceed 12°.

Mr. Harding said that in the operation of his plant, which is one of the oldest in the country, it has been found very much better results are obtained by adjusting the houses to a drop of 40° than where running with a drop of from 25° to 30°. Mr. Schott said in the case of consumers taking water for domestic purposes, a boiler is placed in the return end of the line, and a meter connected. He did not consider it a good proposition to sell hot water.

In reply to a question as to how many average feet of radiation can be taken care of per horse-power of exhaust steam from the engine in the case of hot water heating, Mr. Schott said the average during the season will be 17,500 and on the basis of a temperature of 10° below zero, it will take care of a fraction under 10,000. "Assuming radiation as figured from a proper standpoint, and not throwing onto it a double condensation, this figure is more like 6,800 square feet. This is on the basis of 100 hp." As to the relative amount of horse-power required in a building for heating and for lighting, that depends entirely upon the character of the building. Assuming a store there will be a surplus of steam at all times required for lighting over and above that which is required for heating. In the case of a certain building of sufficient size to require 17,000 ft. of radiation to heat it with steam under normal conditions, 170 hp are required. The load on the electrc end runs as high as 350° and averages about 200 hp. so that the exhaust steam will more than heat the building. In this particular case the owners have agreed to take their heat and power from a central station company, with a minimum guarantee that it will not run over $15,000 a year.

COIL WINDINGS FOR ELECTRICAL PURPOSES.

The next paper to be presented was one on "Coil Windings for Electrical Purposes," by Messrs. Richard Varley and Charles R. Underhill. As there is very little data on the subject and the requirements are so exacting the practical method of obtaining data has been to construct electromagnets of different forms and sizes and make actual tests. Having once found the pull which may be produced through various distances with different magnetizing forces, it is then comparatively easy to determine what size of wire should be used for any given voltage to produce the desired results. The paper then took up various points concerning the manufacture of electromagnets and developed formulæ whereby it is possible to quickly determine the proper size of wire for any purpose.

ELECTROLYTIC RECTIFIERS.

In the absence of the author, a paper on "Rectifiers," by W. Scheidel, was read by the secretary. This dealt more in particular with the construction of an aluminum rectifier which has recently been placed in the market for the charging of storage batteries from alternating-current lines. The main feature is the use of an inactive electrode between the two active electrodes; the former is connected to the middle point of a transformer secondary, and the two latter to the secondary terminals.

INCANDESCENT LAMPS AND THEIR SMASHING POINT.

The last paper to be read at the afternoon session was one on "Incandescent Lamps in General, their Smashing Point in Particular," by George C. Keech. From the very birth of the "smashing point" expression came the thought that the next step toward the ideal lamp was to make one which would automatically die when it had lived out its usefulness. After pointing out the desirability of keeping the illumination up to the standard, the paper then outlined improvements in the process of manufacture whereby, although exactness is not possible, lamps are made which will burn out very close to such a point, and the important result is practically obtained. Such lamps will smash automatically and must be renewed. In the discussion Mr. Keech, in answering to a question as to what he considered a proper "smashing point," said that this is when the candle-power falls to 80 per cent. of normal, or 12.8 candle-power. In reply to a question he said the candle-power are for 3.1 and 3.5 watt-lamps; about 7,200 and 13,800 hours, respectively. Mr. Schott said that the frequent changing of lamps is a good thing to maintain candle-power, but the tendency of cities is to force companies into lower rates, and it is an open question whether they can go to too great expense to maintain it. In reply Mr. Keech said that the average burning of a lamp is, say, two hours per night, and one lamp at half a cent would bring in a revenue of one cent per night; fifty lamps, fifty cents; and in 365 nights those fifty lamps would bring in about $180. In that way fifty dead lamps on the line, if they had been burning, would have meant the sale of $180 worth of current: and, of course, the central station man expects to make his money out of the sale of current. Mr. Schott reported his experience that the average renewals are about a lamp per year for the connected load. For instance, with about 7,000 lamps connected with a station, about 7,000 would be the average number of renewals, which statement applies particularly to a residence territory; if a commercial plant, the percentage of renewals will materially increase. In the ordinary country plant, where anywhere from 30 to 60 per cent. of the connected load is for residence use, about one lamp per year for each lamp connected would be a fair average to consider. In a town of ten to 12,000 inhabitants, 7,000 lamp renewals would cost about $1,400. He uses a 52 to 57-watt lamp (55 on an average). An increase in voltage of 1 per cent. means an increase in candle-power of 6.2 per cent. and an increase in life of 25 per cent. Mr. Keech said that by burning a lamp 3 per cent. high its life will be cut in two, no matter what the efficiency is. A 3.5 watt lamp, burning 3 per cent. high, will last about 54 per cent. and a 3.1-watt lamp on the same circuit will last about 50 per cent. of its life, on the average, because the 3.1-watt lamp is more delicate. In the case of a 110-volt lamp run 3 per cent. high, it would make a 16-cp lamp give 19 cp. The wattage would be forced up about one watt to a volt and the lamp would practically give out 19 candles at 60 watts, which is just about 3.1. As a consequence, a 16-cp lamp burned 3 per cent. high will result in increasing the watts a little, so that when you divide 19 into 59 watts you have a 3.5-watt lamp, which brings it back to where it was in the first place, and the efficiency remains the same.

Mr. Schott considered that one of the worst features to contend with in plants in small towns is the fact that the consumer expects to take one lamp and make it do the work of two. If a filament is white, the average consumer will think it is giving more light than a red one. In large cities where they are educated in this manner and put in the proper number of lights, you can run your lamp under voltage a little bit, and give satisfaction, but in a typical country plant you have to vary from good practice to satisfy your customer and yourself.

DOUBLE-CURRENT GENERATORS.

On Thursday morning Mr. W. L. Waters presented a paper entitled "Double-Current Generators in their Connection with Double-Current Supply," in which he pointed out that the double-current generator offers the best solution in cases where a station supplies both alternating and direct current, owing to the saving both in the first cost and operating expenses. The efficiency is also higher than when rotary converters or motor generator sets are used. The main objection is that the voltage of the alternating-current side of the machine bears a different ratio to that on the direct-current side; that one cannot be varied without the other, and variation of the load on one side affects to a slight extent the voltage on the other side. The relative weight of these objections must be decided in each individual case. From the manufacturer's point of view the great objection to double-current generators is that they are special machines, usually requiring new designs and special patterns and dies.

It was pointed out that some standard direct-current generators can be very conveniently used as double-current generators with only a very slight change in the speed. For example, a standard 2,500-kw, 250-volt engine type machine can make a very good 25-cycle double-current generator, the only change being to provide the machine with collector rings, increase the air-gap, and put more copper on the field magnets in order to make the machine regulate properly when running as an alternating-current generator. These changes would not increase the cost of the machine more than 20 per cent. On the other hand, if a 500-kw, 500-volt engine type machine were taken, it would mean very radical changes to make this into a 25-cycle, double-current generator; 25 or 40-cycle machines are not in any way difficult to design, but in the case of 60-cycle generators difficulties are encountered with the commutator on account of the high peripheral speed; 60-cycle, 600-volt, double-current generator and rotary converters can be made to work, but they are not as reliable as those for lower frequencies, and there is no brush gear at present on the market which is quite satisfactory for the commutator peripheral speeds necessary in a 60-cycle, 600-volt machine. It appears that the most satisfactory 60-cycle, double-current generators will be those driven by steam turbines, and it looks as though this prime-mover would solve this problem.

In summing up Mr. Waters says that, generally speaking, 25-cycle, double-current generators, if of large size, can be direct-connected to the engine, while for sizes smaller than 500 kw they are better belt-driven; 40-cycle machines should always be belt-driven if the cost is to be reasonable, while for 60-cycle, double-current generators, apparently the only reasonable solution is to have steam turbine sets. Of course, double-current generators can be made for any frequency and voltage up to 60 cycles, 600 volts, and for any speed desired; it is simply a question of dollars and cents whether one wishes the most reasonable prices and the quickest deliveries and to have machines which, when second-hand, will be something more than scrap. They should consider the matter of frequencies and outputs when laying out a station for double-current supply.

The discussion of Mr. Waters' paper more particularly related to the construction of double-current generators, and not with the practical application of these to central station work. The president remarked that the use of double-current generators was one of expediency with each individual station. As it is seldom good practice to run an engine underloaded below, say, 50 per cent., it is such a condition to which the double-current generator is especially applicable.

RECTIFICATION OF ALTERNATING CURRENTS.

The convention then listened to the reading of a paper on "Rectifiers," by C. F. Burgess, assistant professor of electrical engineering at the University of Wisconsin. This paper more particularly dealt with the theoretical aspect of the subject, and indicated the direction in which practical results may be expected. Rectifiers were divided into three general types: mechanical, vapor and electrolytic. Omitting the rotary converter, which is essentially a direct-current dynamo driven by an alternating-current motor, and is not a rectifier in the commonly accepted meaning of the term, the mechanical rectifiers include the synchronously-driven rotating reversing switch, and the vibrating reverser in which the contact-maker is maintained in synchronous vibrations by energy derived from the alternating circuit. Various inherent defects have prevented these devices from being extensively adopted in spite of their low cost, as compared with the rotary converter.

A class of electrolytic rectifier only recently placed upon the market in this country is sometimes designated an electrolytic valve, and, as such, has an analogy in the hydraulic check valve, which automatically allows water to flow freely through a pipe in one direction, but prevents its passage in the opposite direction. With the commercial frequencies now employed, of from 25 to over 100 cycles per second, it is evident that this valve must act with great rapidity. As the result of laboratory investigation, it has been shown that an aluminum plate immersed in a sodium nitrate electrolyte required about 1/1100 second for closing the electrical valve at each reversal of pressure.

Among the advantages of such a rectifier are that it possesses no moving parts; it is a close approximation to the static alternating-current transformer, requiring little or no attention during operation. The materials of which it is constructed are cheap, and the total cost should be lower than that of the ordinary transformer of equivalent outputs. The electrolytic rectifier has a high power factor. It requires little or no abnormal rush of starting current. In its present condition, it has an efficiency in the neighborhood of 50 per cent. In small sizes this form of rectifier is especially advantageous for the charging of small storage batteries from alternating-current circuits.

With aluminum electrodes 2 x 1 x 1½ in., a normal load of 10 amp. can be obtained at a rectified pressure of 25 to 50 volts. The current may be several hundred times higher than this value for a short time, without detriment, and a 50 per cent. overload causes excessive heating and vaporization of the salt, only after several hours' run. The total weight of an output of this capacity is about 30 pounds, most of which is in the transformer. The greatest use which the electrolytic rectifier finds at present is in the charging of storage batteries for various purposes, and its commercial introduction will afford an additional market for the central station product.

The discussion served to show that the future of the rectifier in smaller sizes is a promising one, and that although the efficiency may not be as high as may be desired, it nevertheless will fill a want for the charging of storage batteries for automobile and other purposes.

STANDARD ALTERNATING-CURRENT PRACTICE.

The first paper to be read at the Wednesday afternoon session was on "Standard Practice in the Use of Alternating-Current Electrical Apparatus," by J. J. Gibson. In the absence of the author, Mr. J. R. Kimball read the paper. Referring to the revolving armature generator, it was stated it still retains some advantages for both belted and direct-connected units in the smaller sizes; but the revolving field generator has become a fixture for all others. The question of direct-connected versus belted units is one which has been quite definitely decided in practice. The question of synchronism in throwing alternators together in parallel, is most frequently determined by the lighting up of the synchronizing lamps when the machines are in parallel. The most satisfactory method, however, has proved to be the one employing a synchrnoscope, as it has the advantage of the lamp method because it shows the slightest difference in phase or frequency, whereas lamps do not. As to frequency, for a pure and simple power proposition, 25 cycles has come to be standard. It gives low speed for motors, and although rotaries are successfully built and operated on 60-cycle systems, still the design of the 25-cycle rotary is less difficult and expensive. For lighting and power 60 cycles per second has come to be the accepted standard, as this frequency is not too high for power, either in motors or rotary converters, and it is about the lowest allowable frequency for successful operation of arcs and incandescents.

As to choice of number of phases, stations carrying an incandescent lighting load alone, with no prospect of ever having a power load, should use single-phase apparatus. A single-phase distribution is not suitable for the operation of motors. It is necessary in a station carrying a mixed load to use polyphase generators, which supply different systems of feeders—polyphase feeders for power circuits, and single-phase feeders for lighting circuits. Three-phase distribution for power calls for about three-quarters of the copper which would be used in two-phase distribution. On the other hand, it is easier, on a lighting load, to keep two than three phases balanced, and the lowering transformer equipment is more expensive in three-phase distribution. For a station, therefore, operating a mixed load, where lighting predominates, two-phase is far better than three-phase. When the power load increases to a point where 25 per cent. of the copper in that branch of the service becomes a considerable item and amounts to more than the saving in transformers, then three-phase distribution is the proper thing to use.

For transmission lines three-phase is universally adopted, although in stepping down for distribution from transmission lines, the current is very often changed to two-phase, in order to obtain the benefits of such regulation. As to choice of voltage in the case of central stations operating lights and motors, 1,100 and 2,200 volts are at present standard. Where necessary alternators can be wound to deliver 6,600 to 11,000 volts. For industrial plants, where the current must not be sent a very long distance, 220 or 440 volts are used, thus doing away with the necessity of lowering transformers. Mr. Gibson considers that the single-phase transformer is best, and that the three-phase transformer will never be more than a specialty. The induction motor, although essentially a constant-speed motor, like the shunt-wound, direct-current motor, is being applied to variable-speed work. Synchronous motors are the exception, and not the rule, and in very many cases are being discarded for the induction motor. Double-current generators are specialties, and not standard practice. Alternating-current arc lamps are finding extensive application as they enable the central station man to use one system for all classes of service.

STORAGE BATTERIES IN SMALL CENTRAL STATIONS.

Mr. J. H. S. Waring then read a paper in which he took up the specific cases of a lighting station in a typical small village and showed the benefit of installing a storage battery in connection therewith. In this case it usually proves unprofitable to furnish continuous service throughout 24 hours, owing to the small demand during the early morning hours and during the greater portion of the day. On the other hand, a central station operating only on the night schedule is greatly handicapped since the owners of residences naturally demand lighting during all hours of the night, and would probably desire fan service throughout the day during the summer months.

The plant considered consists of one 60-hp and one 120-hp non-condensing engines, which, in addition to driving certain machinery, operate two 220-volt geerators, one of 20 and the other of 25 kw, connected to a three-wire system with 220 volts across the outers. The maximum peak load of 150 amp. was on the station for about an hour and a half in the evening; that is, from 6.30 to 8 P.M. It then gradually decreased to about 10 amp. at 11 P.M. and at midnight the plant was shut down. A storage battery was then put in; the machinery operated the same number of hours as previously, and current supplied from the storage battery for the remainder of the day. A 110-volt battery was installed, and the two outer wires connected together at the station, the system thus operating as a two-wire, 110-volt system with a considerably less drop than when operated as a three-wire system with maximum load. There was an increase in load after the installation of the battery of about 60 per cent. and an increased fuel consumption of only about 25 per cent., showing that the cost of fuel per kilowatt-hour was decreased about 37 per cent., which decrease was due to the fact that the generator set while operating with the battery was run at a considerably higher percentage of full load than previously.

Another case was cited of a plant which supplied current to outlying districts. While the alternating load was extremely heavy during the peak, it was very light during the day, consisting only of a small amount of fan service in the summer months. A battery was installed in this plant which furnished current directly to the direct-current motors and at the same time operated a direct-current motor running a small alternator, so that the fans on the alternating-current system could be used.

Another application of the storage battery referred to and irrespective to the size of the plant, is in connection with a water power plant. There are many cases where there is sufficient water power to supply considerably more than the load existing during the greater part of 24 hours, but not sufficient for the peak load. In this case the generators, while carrying the day load, can charge a battery, the same being discharged at the time of the peak load.

Another application of the storage battery referred to is that of placing it at the center of the load of a direct-current system of distribution. When the volume of business in a congested locality reaches a certain volume (and the more remote the sooner is this point reached), the amount of copper required to care for the power from the station tends to render this system of distribution impracticable. By the installation of a battery of sufficient capacity to care for a certain portion of the peak, the amount of copper between the central station and the center of the load is decreased to such an extent that the battery investments is decidedly a good one from the commercial standpoint. A recent adaptation mentioned of the storage battery is its use with direct-current exciters in alternating-current power and lighting plants. With a storage battery floating at all times on the exciter, power interruptions of current in the exciter circuit are practically obviated, fluctuations on the exciter voltage are reduced with corresponding reductions in the alternating-current voltage fluctuations. Where alternating-current motors are used to drive the exciters, the battery also serves to supply field current when starting up the plant after a shut-down.

At the conclusion of his paper, the author showed a number of lantern slides, which served to illustrate some points of interest in lighting work and storage batteries. Among others was shown the new type of negative plates of the Electric Storage Battery Company, known as the box negative. In this plate the active material is held in place by perforated lead sheets on each side of the plate, which thus prevents the loss of the active material. In a laboratory test, after 8,000 complete discharges of the plate, a depreciation of less than 1 per cent. was noticeable.

In answer to a question, Mr. Waring stated that the latest practice of his company was to place wooden separators in the battery after they had been in operation for about a year. Mr. Lukes cited the advantages of the storage battery on railway circuits in order to prevent the abrupt fluctuation. These fluctuations are very severe, the load changing from almost zero to perhaps 50, or even as high as 150 kw. Mr. Waring said the use of a storage battery in conjunction with a street railway plant is perhaps the most common application of storage battery work in large stations. One application is to take off the fluctuations of the railway load, so that all machines may be belted to one shaft, thus avoiding trouble with regulation on lighting circuit. In a recent case a firm of consulting engineers made a test on an interurban system where there were three sub-stations with a storage battery in each. They made a test of a sub-station, running with the rotaries alone, the batteries being out of service; the next test was made with the battery running without a booster, the battery merely floating; and the third test was made with the battery operating with booster in conjunction with rotaries. In that case the fluctuations either side of the average voltage were 3 per cent. on a 600-volt system, when the battery was operating with booster; when the battery and booster were off the voltage fluctuation was 16 per cent. under just about the same load variations. In that case they were not aiming at voltage regulation, because it made no difference whether the rotaries did vary somewhat, but that may serve as an illustration of what it will do. In reply to a question, Mr. Waring said that in most interurban practice he figures on certainly not over 100 watt-hours per ton-mile for cars, and the starting current will vary from two to three times the average current. That does not mean necessarily a large-sized battery, because the battery only has to take care of the fluctuation momentarily, and not for any length of time.

THE CURTIS STEAM TURBINE.

Mr. James Lyman presented a paper with this title, which opened with an account of the fundamental principles of the steam turbine, and compared the Curtis type with those of Parsons and De Laval. The former was then described in detail and its advantages over the reciprocating steam engine pointed out. With respect to regulation, it was stated that in the case of a 1,500-kw Curtis turbine with a mixed load of lighting, induction motors and railway power with momentary fluctuations of 200 kw, the load ranging from 500 to 800 kw, the speed varied less than 2 per cent., with the boiler pressure varying all the way from 75 to 150 pounds. It was added that no reciprocating engine could give such regulation. Experience with Curtis turbines in operation and deductions from their form of construction, show that the repair account will be exceedingly low, making a large saving as compared with the operation of reciprocating engines. One of the advantages adduced in favor of the Curtis turbine is that, when used in connection with steam heating plants, it can be changed from condensing to non-condensing without shutting down. The heating system can be connected with the first stage or free exhaust and regulated for several pounds back pressure by adjustment of the second stage valves; thus, where all the exhaust system is not required for heating, it can be efficiently used by the turbine. Another advantage noted is that the Curtis turbine in running is almost noiseless. Following is a list giving the sizes of Curtis turbo-alternators now made by the General Electric Company: For 60 cycles; 500 kw at 1,800 r.p.m.; 1,500 kw at 900 r.p.m.; 3,000 kw at 600 r.p.m., and 5,000 kw at 514 r.p.m. For 25 cycles: 2,000 kw at 750 r.p.m., and 5,000 kw at 500 r.p.m. It was stated that the General Electric Company has sold 122 turbo-alternators aggregating 206,500 kw; 25 of the units have already been shipped and about half of them are now in regular commercial operation.

RADIUM AND RADIOACTIVITY.

The last number on the programme was an illustrated lecture on "Radium," by Prof. R. A. Millikan, of the University of Chicago. This was a pleasing diversion from the technical papers discussed at the convention, and, furthermore, was a very instructive lecture on a subject which is arousing the greatest interest, not only among scientists, but among laymen as well. The lecturer treated the subjects under the following heads: Discovery of X-rays; discovery of radioactivity; discovery of radium; nature of cathode rays; new theory as to the constitution of matter; nature of X-rays; radioactive substances emit cathode rays; other radiations from radioactive substance; nature of alpha-rays; the Crookes spinthariscope; continuous emission of light and heat by radioactive substances; radioactivity a manifestation of subatomic energy; production of uranium rays; the emanations from radium; induced radioactivity; the birth of helium; the life of radium; the transmutation of the elements; sub-atomic energies.

As will be seen from the above enumeration, the lecture covered a great extent of ground. The historical development was considered in each case and the views by different authorities as to the nature of the various radioactive phenomena given. In conclusion, Prof. Milliken says that the studies of the last eight years upon radiation seem to indicate that in the atomic world at least some of the heaviest and most complex atomic structures are tending to disintegrate into simple atoms. The profoundly interesting question is thus suggested whether there is any natural process which does, among the atoms, what the life process does among the molecules, namely, which takes the simpler forms and builds them up again into more complex forms. Prof. Milliken thinks that it would be rash to attempt to give any positive answer to such a query, yet the fact that radium now exists on the earth, taken in connection with the fact that the life of radium is short in comparison that the ages the earth has been in existence, certainly seems to point to an affirmative answer. The experiments of the last eight years have marked a remarkable advance in science in that they have proven the existence of an immense store of sub-atomic energy. It seems highly improbable, however, that this energy can ever be utilized on the earth to serve man's economic needs, for thus far we know of but three substances which are disengaging this sub-atomic energy and these are changing so quickly that the rate of evolution of energy is almost infinitesimal. Radium may possibly prove to be of some practical value in the cure of diseases, although it is too early yet to ascertain this with certainty. But even if no practical application of this discovery should be found, radioactivity will, nevertheless, have served the most useful of all ends, namely, that of enlarging man's knowledge of the ways of nature and of deepening his insight into the constitution of matter.

The report of the nominating committee, which submitted the following names for officers and directors for the following year, was adopted, and the following declared elected: For president, T. F. Grover, Fond du Lac, Wis.; first vice-president, George H. Lukes, Evanston, Ill.; second vice-president, E. A. Daniell, Menominee, Mich.; secretary-treasurer, Thomas R. Mercein, Milwaukee. Directors—W. H. Schott, Chicago; D. C. Jackson, Madison, and H. Almert, Oak Park, Ill.

Thursday evening the annual banquet was held at Hotel Pfister, as usual.

The following members were in attendance at the convention: T. F. Grover, vice-president and general manager Eastern Wisconsin Railway & Light Company, Fond du Lac, Wis.; C. F. Burgess, assistant professor of electrical engineering, University of Wisconsin, Madison, Wis.; L. Owen, assistant superintendent Peoria Gas & Electric Company, Peoria, Ill.; J. H. Harding, treasurer and superintendent La Porte Electric Company, La Porte, Ind.; George H. Lukes, general superintendent North Shore Electric Company, Evanston, Ill.; Harold Almert, manager Cicero Light, Heat & Power Company, Oak Park, Ill.; R. Kimball, vice-president and superintendent Kenosha Gas & Electric Company, Kenosha, Wis.; H. W. Frund, secretary and manager the Vincennes Electric Light & Power Company, Vincennes, Ind.; F. W. Bowen, president; Thomas R.

Mercein, secretary; J. S. Allen, Beloit Electric Company, Beloit, Wis.; Irving P. Lord, Waupaca, Wis.; H. F. Pearce, Negaunee, Mich.; G. R. Lindsay, Manawa, Wis.; P. H. Korst, Janesville Electric Company, Janesville, Wis.; Edward Danfield, manager and secretary, Menominee & Marinette Light & Traction Company, Menominee, Mich.; P. L. Utley, manager Watertown Electric Company, Watertown, Wis.; Fred W. Insull, secretary North Shore Electric Company, Evanston, Ill.; William B. Jackson, Madison, Wis.; Mr. Rau, the Milwaukee Electric Railway & Light Company, Milwaukee, Wis.; D. B. Bronson, Chicago Edison Company, Chicago, Ill.; G. N. Eastman, Chicago Edison Company, Chicago, Ill.

The Lamme Single-Phase Series Motor.

The first issue of the *Electric Club Journal*, published by the Wilkinsburg Electric Club, contains an article by Mr. Charles F. Scott, entitled, "The Single-Phase Series Motor in Its Relation to Existing Railway Systems." After sketching the development of the electric railway and its present status, and pointing out how the advent of the series alternating-current motor has created a radical new situation in the electric railway field, it is stated that at first a frequency of 16⅔ cycles was employed for the Lamme single-phase motor, but experience gained in the construction and tests of a number of motors have led to the design of motors for 25 cycles equal in performance to the earlier motors at the lower frequency. The adoption of this frequency, moreover, makes present alternators available for the operation of the alternating-current motor, and, in fact, they may be used for supplying current to the cars equipped with the new motor and for supplying direct current through rotary converters to old cars.

It is stated that an unique feature of the alternating-current motor which is now being considered is its conformity to the standard type of direct-current motor. The former is also a first-class direct-current motor, being a type that can be operated indifferently on alternating current or on direct current. While this characteristic will be of little or no consequence with respect to new installations, there are many cases where it is necessary or at least desirable to operate from a direct-current trolley. Lamme single-phase series motors are normally wound for 250 volts, so that if two are connected in series they can operate on a 500-volt direct-current circuit. Two single-phase motors connected in series can take the place of one direct-current motor, and a four-motor equipment motor, therefore, may be operated with the ordinary direct-current type of series parallel control. A two-motor alternating-current equipment, if operated by direct current, would make it necessary that the whole control be by means of a rheostat in the same way that a single direct-current motor would be operated.

An equipment of single-phase motors with rheostatic control may be operated either on a 500-volt, direct-current circuit or on a 500-volt alternating-current wound circuit, or on a high-voltage trolley circuit of, say, 1,000 to 3,000 volts, the voltage being reduced by transformers on the car. A given car, therefore, may start in a city which has a 500-volt system, running along with local cars from the same direct-current trolley; it may then go across country with alternating current at high voltage and then through a village taking alternating current at 500 volts, and then take high voltage again, as may be convenient. It is true that this arrangement will prevent the use of variable voltage control. The advantage in voltage control, however, is greatest in those cases where stops are frequent, or where the motor is run at low speed during a considerable portion of the time, as it is in these cases with rheostatic control that the rheostat is in service a considerable part of the time with corresponding loss; but the loss in the rheostat of an ordinary suburban car will be relatively small if stops are infrequent. It is, theoretically, possible to install both the rheostatic and the voltage control on the same car, but in general this is not advisable on account of the weight, cost and complication of the double system of control.

More Radium.

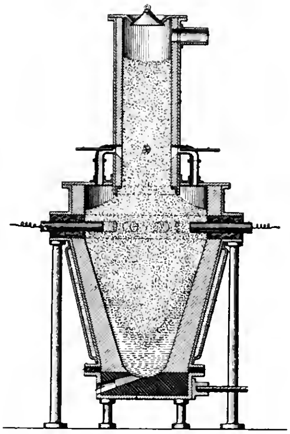
The State of Texas is the latest aspirant to the honor of being a radium-producing region. According to a press dispatch from Austin, vast quantities of earth containing radium compounds have been discovered in the Llano mineral region near that city. It is further asserted that scientists claim that these earths will yield more radium than any other known deposits in the world.

Recent Electrochemical Developments.

RESISTANCE FURNACE FOR THE MANUFACTURE OF CALCIUM CARBIDE.

Three patents were granted on January 19 to Mr. Alfred H. Cowles, of Cleveland, Ohio, all referring to the manufacture of calcium carbide in an electric resistance furnace. He proposes to pre-heat the charge, for example a mixture of lime and carbon, by withdrawing the waste carbon mon-oxide from the furnace and burning it in the pre-heating chamber. The resonance furnace itself is so designed that the current density increases towards the bottom of the furnace so that the temperature is highest at the bottom, thus giving a sufficient fluidity to the calcium carbide to permit it to be tapped.

The adjoining illustration shows one of the various furnaces for this purpose. It is an annular stack of refractory non-conducting material, enclosed by a casing of iron. The major portion of the body is a downwardly-converging bosh surrounded by a water jacket. The hearth of the furnace consists of a solid mass of carbon set in an iron casing which is insulated from the upper casing of the furnace. A



CALCIUM CARBIDE FURNACE.

tap-hole for the molten product extends through the hearth. The hearth serves as one electrode, while the other electrode consists of a number of radial carbon rods passing horizontally through the side walls of the furnace near its top.

Supported upon an opening into the upper end of the furnace is the pre-heating chamber, consisting of a shell of iron with a lining of refractory material. The upper end of the pre-heating chamber has a *bell-and-hopper* charging mechanism. Pipes for withdrawing the combustible gases from the electric furnace extend upwards through its top and are connected to burners with air-blast pipes, which enter openings in the sides of the pre-heating chamber.

BATTERY INVENTION.

A patent granted to Mr. Oskar Frank, of Detroit, Michigan, refers to the mechanical construction of a grid for pasted storage battery plates. Another patent granted to Mr. F. A. Feldkamp relates to a method of producing a storage battery plate. A perforated metal plate is wrapped in layers of an open-mesh fabric such as mull, linen, mosquito netting, etc., and the active material in a plastic state is pressed into the layers of fabric.

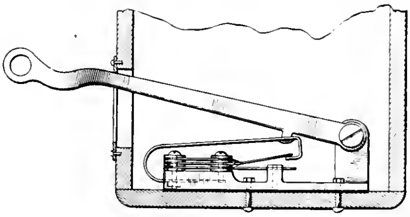
ELECTROLYTIC EXTRACTION OF GOLD.

Two recent patents granted to Mr. H. R. Cassel, of New York City, refer to a method and apparatus for extracting precious metals by electrolysis. In the electrolytic vat the anodes and cathodes are vertically arranged, and the pulverized ore, after having been converted into a pulp mixed with cyanide of potassium, is introduced into the vessel. The stream of constantly flowing pulp is diverted to the anodes, the particles of gold being thus brought into intimate contact with the same and rapidly dissolved. The cathodes are continually covered with mercury so that the gold is precipitated upon the cathodes as an amalgam. Means are provided by which the pulp is constantly circulated through the vat from the top to the bottom and then through a pipe back to the top. Means are also provided for continually amalgamating the cathode by a circulation of mercury, the cathodes being blanked by a number of slats or deflectors which are inclined from top to bottom toward the cathodes and serve to continoually throw the mercury as it rebounds from the cathode back upon the same, and effect the rapid accumulation of amalgam. The mercury which collects in the bottom of the cell is returned by means of a pipe to an acid chamber at the top where any alkali in the mercury is neutralized.

New Telephone Patents.

NEW FORM OF HOOK SWITCH.

The telephone hook switch has undergone a very considerable change in the last few years, the older type in which the hook itself sufficed for a switch blade having been almost entirely superseded. Of the superseding types, that in which the hook serves as a switch lever operating upon a key composed of flat springs is the most prevalent. Many admirable varieties of such a hook-switch have been developed, the latest being that described in a patent recently issued to E. E. Yaxley, of Chicago. A side view of this switch is shown in the figure. As will be noted, the spring controlling the hook is so formed as to engage the extremities of all of a nest of springs assembled in the manner customary for switchboard keys. The uppermost spring is bent so that its extremity lies in the same horizontal plane as the middle spring, both springs normally resting upon an insulating bridge underneath which the movement of the lowest or bell spring takes place. The American Electric Telephone Company, of Chicago, has obtained the patent for this excellent switch.



YAXLEY HOOK SWITCH.

NEW SIGNALING CIRCUITS FOR TWO-WIRE SWITCHBOARD.

A modified system of circuits for signaling in connection with two-wire central energy switchboards forms the subject of a patent granted to K. B. Miller, of Chicago, and assigned by him to the Kellogg Switchboard and Supply Company. The novelty lies in the supervisory circuits in which a plug socket switch is so associated with the lamp circuit that this circuit is opened whenever the plug is in the seat. By the use of such means one relay in the cord circuit is sufficient to properly control each signal, instead of the two usually required. The ultimate economy of such an arrangement is, of course, extremely questionable because of the uncertain habits which experience has shown plug socket switches to possess.

PARTY-LINE DEVICE.

It is, of course, a well-known fact that with party-line working any subscriber may ordinarily hold up a whole line by allowing his receiver to remain off the hook. Undoubtedly here and there considerable difficulty is found from this cause especially on lines where there is a particularly irritable subscriber. Therefore, the idea of Mr. N. E. Noistrom of overcoming this difficulty by bringing the control of the connection between each station and the line into the hands of the central office operator would be an admirable one, provided it could be obtained with less cumbersome apparatus. Unfortunately, he has worked out the problem for a step-by-step party line system and his solution is, therefore, subject to all the limitations of such a system.

Use of the Electrophone.

In connection with a recent tariff speech by Mr. Joseph Chamberlain at the Guildhall, London, the *Evening News* issued an electrophone edition, containing a verbatim report on sale fifteen minutes after the delivery of the speech.

CURRENT NEWS AND NOTES.

TELEPHONING FIRE ALARMS.—It has been the practice of the Wisconsin Telephone Company in Milwaukee to suggest in its telephone directory that patrons send in fire alarms by telephone. The chief of police has requested the manager of the telephone company to omit this suggestion from the book hereafter, for the reason that it frequently takes too long a time to notify the fire headquarters by telephone. This delay gives the fire a chance to gain a good headway before the department is able to respond to the telephone fire call.

HARVARD UNIVERSITY AND MASS. INST. OF TECHNOLOGY.—A press dispatch from Boston states that an alliance of Harvard University and the Massachusetts Institute of Technology is a future possibility. It is pointed out in the dispatch that such an arrangement would be merely an alliance, and not an absorption of one institution by the other. The result would be the limitation of the Lawrence school at Harvard to pure science and the transfer of all Harvard engineering instruction to the Institute of Technology. What is drawing the attention of the Harvard overseers and the technology corporation to the suggestion, the dispatch adds, is the economy and the idea of stopping the actual waste of money and energy involved in the upbuilding and maintenance of two rival technical institutes three miles apart. The project is yet in an embryotic state, and no direct negotiations have yet been undertaken.

CINCINNATI MEETING OF A. I. E. E.—The Cincinnati local branch of the American Institute of Electrical Engineers held its first annual meeting at the Grand Hotel on the evening of January 18. The business meeting was preceded by a dinner in which forty members, associates and guests, participated. The following officers were appointed: Chairman, Mr. B. A. Behrend, chief engineer Bullock Electric Manufacturing Company; vice-chairman, Mr. J. Hendrick Hallberg, general superintendent Cincinnati Gas & Electric Company; secretary and treasurer, Mr. Louis E. Bogen, civil and electrical engineer Bullock Electric Manufacturing Company, late professor of Electrical Engineering at the University of Cincinnati. After the business meeting the chairman introduced Louis Trenchard More, professor of Physics at the University of Cincinnati, who delivered an instructive, interesting talk on radium, exhibiting several photographs taken with radium and also a specimen of radium chloride. The lecture was followed by a general discussion on the new ideas in molecular physics and the great scientific importance of radium in such questions as the age of the earth and the revision of our views of the molecular theory of matter. The local branch has been started with energy and enthusiasm, and the management is arranging with able and representative engineers to lecture before its members.

INDIANA ENGINEERS' SOCIETY.—The 24th annual convention of the Indiana Engineers' Society was held in Indianapolis on January 14, 15 and 16. In his annual address, President R. L. Sackett dwelt upon the evolution of the engineer. Several papers relating to electrical subjects and development were read. The report of the committee on electrical engineering stated that progress was so great that it was difficult for the most diligent engineers and students to keep up with it. Among the many papers read were the following: "Smoke Prevention," by R. P. King; "A Description of the New Centralized Power and Heating Plant at Purdue University," Prof. J. D. Hoffman; "Power Chains and Their Uses," by C. H. Hills; "The Railway Profile Considered with Reference to the Propelling Power of Locomotives or Electric Railway Motor," by Prof. W. D. Pence; "The De Laval Steam Turbine," by G. A. Young; "Interurban Railways in Small Cities," by J. W. Fulwider; "Special Street Railway Work," T. B. McMath, and "Surveys for Electric Railway Construction," by C. L. Sellers. As to electric railway engineering it was claimed that a level track was by no means necessary; that an undulating track, otherwise properly constructed, was not detrimental to successful operation. Mr. Sackett was re-elected president and J. B. Nelson vice-president. The next convention will be held in Indianapolis on January 13, 14 and 15, 1905.

DISSATISFIED TELEGRAPHERS.—It is stated that the 1,500 telegraphers employed by the Baltimore & Ohio Railroad have placed a demand with the company for shorter hours and an increase in wages. The main complaint is to the effect that the operators are kept at work in the towers longer hours than they are paid for.

INTERNATIONAL SUPPLIES.—The *World's Work* for February notes the fact that in the large power plant installed in the Mysore country in Southern India, the timber came from Australia, insulators from Italy, the hydraulic plant from Switzerland, the penstock pipes from Scotland, and the entire electric plant from America.

AN APOLOGETIC CORPORATION.—By way of making apology to the public for the bad trolley service in northeast New Jersey, the Public Service Corporation carried two columns of advertising matter in the columns of several of the local newspapers in the form of a statement signed by President Thomas N. McCarter. He admits that the service is bad, but says this is caused in part by changes necessary when the competing lines of North Jersey were merged, but more especially from the fact that the rolling stock acquired was in such a miserable condition that in the recent cold snap there was hardly a car that did not give out in some essential part after one or two trips. No relief is promised until spring, when open cars can be used and new cars being built will be delivered. After advising patience, the address concludes with a paragraph that has caused considerable adverse comment. It is as follows: "The Public Service Corporation has every disposition to comply with all reasonable demands of the public and regulations of municipal bodies. It cannot, however, thoroughly reorganize and largely re-equip an extensive street railroad system in a few months. Unreasonable and vexatious ordinances and impositions can only result in additional delay in the efforts of the company to improve its system, and will, of course, be contested if enacted. The strike of last summer followed by the flood and the severity of the present winter, have added considerably to the strain upon the facilities of this company to discharge its duties to the public. Besides, harsh and intemperate criticism tends to demoralize discipline and weaken the efficacy of the service."

ELECTRIC TRUCKS.—The following from the New York *Herald* looks like a partial or prejudiced statement: "After a thorough trial of self-propelled trucks for delivery work, several of the leading brewers of New York have decided to discontinue the service and replace with horse-drawn vehicles all automobiles now in use. Purchased primarily for advertising purposes, the electric brewery trucks have proved to be too expensive and unreliable to warrant their retention even for this purpose. One brewer who paid $4,500 apiece for eight of them about two years ago has offered, it is said, to throw off the $4,000 and take $500 around for the lot that he has on hand. Failing to find buyers for the second-hand motor trucks, he says, he will consign them to the scrap heap in preference to using them longer. The constant replacing of batteries, which cost about $750 each, and of tires, which cost $250 a set, makes the machines enormously expensive to maintain, and, notwithstanding the high cost of operating them, they are always breaking down on the road, preventing prompt deliveries and thereby hurting trade. Scarcely a day passes, it is said, without having to send out a pair of horses to drag one or more of the disabled motor trucks back to the repair shops. The brewer referred to announced when he purchased the first automobiles that he intended to use them altogether as soon as he could get rid of his horses and obtain enough machines to do the work. The shoe is now on the other foot. The machines having been tried and found wanting, he has decided to discard them altogether and use horses exclusively in the future. To this end he has just placed with Fiss, Doerr & Carroll a larger order than ever before for fancy draught horses of the brewery weight and quality to take the places of the discredited machines. Business houses that have experimented with the motor vehicles for light delivery work are in some instances no better satisfied than the brewers and are either discarding the costly toys outright or endeavoring to exchange them for horses and horse-drawn wagons. Fiss, Doerr & Carroll say they have been flooded with requests to take motor vehicles in part payment for horses, but, knowing of no way to dispose of the second-hand machines, have declined all such offers."

LETTER TO THE EDITORS.

Theories in Wireless Telegraphy.

To the Editors of Electrical World and Engineer:

SIRS:—Owing to absence in Europe my attention has only now been called to the letter of Mr. J. E. Taylor in your issue of December 26, and that of Prof. Blondel in the following issue. To discuss first M. Blondel's letter, I would say that the positions taken by M. Blondel and myself are really identical in regard to every single point discussed, and that where M. Blondel assumes a difference this is due to a misunderstanding. For example, M. Blondel states in his letter, paragraph 3, "If Prof. Fessenden has found this height very limited it is, I believe, simply because the energy decreases rapidly as the distance from the earth increases." Now there is no statement in any article or letter by me that I found the height very limited. As a matter of fact, as will be seen by a perusal of some of my articles, my method was to find the height at which the intensity decreases to 1/E th of the initial value. For example, in a previous article, I point out that waves 500 feet long penetrated about 8 inches into salt water, and about 2 feet into ordinary soil, before falling off to 1/E th of their intensity. That the height is, however, actually limited is true, as is shown by my measurements, and in this M. Blondel agrees with me for he states in his article, last two lines, "And present a maximum effect toward the horizon and *no* effect toward the zenith."

With reference to M. Blondel's statement that I have not taken account of the very great sensitiveness of the gold coherer, I would say that a reference to my article will show that I *have* done this, for in my article in these columns, October 31, page 728, I gave a table showing that the gold coherer is four times as sensitive as the regular coherer.

In addition, I would say that I was perfectly aware of the fact that the gold coherer can be made to have great sensitiveness, but as mentioned in my article, "In making this comparison the coherers were adjusted to be as sensitive as possible *without giving false signals*," and an experience of five years in working with coherers of gold and silver and their alloys has shown me that when gold coherers are adjusted so as to be more than four times as sensitive as the ordinary coherer they become unreliable and are influenced by vibration, etc.

With reference to the question of syntonization by group frequency, I would point out that this is undoubtedly a case of simultaneous invention, as though M. Blondel's patent was filed May 3, 1900, mine was filed June 2, 1900, and the specification itself was actually drawn up in October or November, 1899.

The same would appear to be the case with reference to the method for the continuous production of waves, as though M. Blondel's patent was granted July 11, 1902, my patent was filed June 6, 1902, and granted August 12, while the experiments on which it is based were made more than a year earlier.

Personally, I would say that putting the commercial question to one side, it has given me considerable pleasure to find that my own ideas have been running concurrently with those of so eminent an electrician as M. Blondel, and this coincidence may possibly be taken as indicating that the theory of the subject rests upon a sound foundation.

The above will show, I believe, that the supposed points of difference between M. Blondel and myself do not exist and that our opinions are really identical. With reference to other points, I am happy to say that my measurements entirely corroborate the theory as given in his last paper by M. Blondel.

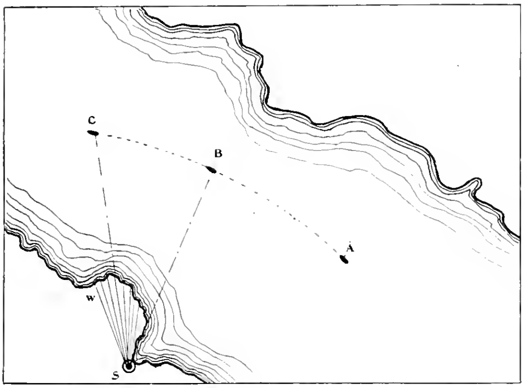
First, they prove absolutely that the energy falls off as the square of the distance, and hence that the waves are "Space propagated," i. e., they are spread over approximately spherical (hemispherical) surfaces, and not along a simple circular belt, which latter theory is held by Mr. Taylor. M. Blondel agrees with me, paragraph 3, in stating that Mr. Taylor is incorrect in attributing to the half waves a constant height. This was as I pointed out and is proved conclusively by my actual measurements of the height.

M. Blondel states that the energy decreases rapidly as the distance from the earth increases, as indicated by an energy curve which figures in his paper. This fact was, I believe, first indicated by me, and referred to in my article mentioned above, page 728, last paragraph from bottom, "The intensity was strongest near the ground and diminished upwards, instead of the reverse, as would have been the case if the effect had been due to diffraction."

On re-reading M. Blondel's paper I see, however, that there is one point in which our ideas possibly do differ, *i. e.*, on the effect of the earth.

This question is rather complicated and I intend discussing it in a separate article. For the present I will give an actual practical illustration of its use which I think will indicate that there is something more required besides actually grounding the conductor. In the experiments above referred to a station was erected on the shore of an island at the point *S*, the island having roughly the shape shown in the accompanying figure. The island was formed of a mass of rock with slight patches of grass but without any soil upon it. The antennæ was grounded by a plate inserted in the water so that the resistance as actually measured between the antennæ and ground was only a few ohms.

A second set of apparatus was placed upon a tug boat having a 50-foot mast. When the tug boat was in the position *A* signals



WIRELESS TELEGRAPH EXPERIMENTS.

were received as far as the boat could go on the opposite side of the bay, *i. e.*, about 15 miles. On the tug boat passing around to the point *B*, while a message was being received on the boat the message was cut off in the middle of a word, absolutely, sharply and decisively, and communication was established equally as sharply on the boat reaching the same position when moving in the opposite direction. At all points beyond *B* in the direction of *C* it was impossible to obtain any communication. A wave chute was then laid over the surface of the island, consisting of a galvanized iron wire spread out in a fan shape and grounded in the water as shown at *W*.

As soon as this wave chute was constructed, communication was immediately established when the tug boat was in the position *C*, and on the tug boat moving off in that direction, a distance of 14 miles, the intensity appeared to be, if anything, stronger than in the direction *A*.

Bearing in mind, as mentioned, that the antennæ was grounded both before and after the construction of the wave chute, to a large plate of copper immersed in the sea and having a ground resistance of only a few ohms, it will be realized that *merely grounding the conductor is not the essential thing*. In fact, as M. Blondel has pointed out, the actual *metallic* grounding of the conductor is not necessary, as it may be grounded through a condenser. Of course, to insure any good results the condenser must have very large capacity, and merely terminating the lower end of the antennæ with a knob or Léyden jar is not sufficient, unless the outer coating of the Léyden jar is at the same time directly connected to earth. I am prepared to say positively that the real essential thing is not a metallic ground connection, but the existence of a natural or artificial wave chute.

It is quite possible that even in this there is no real difference of opinion between M. Blondel and myself, and that my statement as to the necessity of either a *natural* or artificial wave chute has been overlooked.

With reference to the sensitiveness of the liquid barretter, I am giving myself the pleasure of forwarding one of these receivers to M. Blondel, and I am convinced that he will find that I have understated rather than overstated its sensibility. From our last tests, this receiver appears capable of working a distance of 250 miles over land with the expenditure of one-quarter of a horse-power and verticals 140 feet high.

With reference to Mr. Taylor's communication, the whole point may be summarized by an extract from his letter of December 26: "How he (Prof. Fessenden) can possibly argue that the intensity can vary with the square of the distance on any 'sliding wave' theory under perfect conditions of transmission, is quite beyond me. When this is the case the waves are space propagated. That is, they are spread over a spherical or roughly spherical surface and not along a simple circular belt." In other words, Mr. Taylor still believes that the waves are propagated in the way he described them in his paper, *i. e.*, in an approximately circular belt, the waves being of constant height as is shown in the figure in his paper, reproduced in M. Blondel's article January 2, 1904, and he considers the idea that they are propagated in an approximately spherical surface as a *reductio ad absurdum*.

Now the mathematical theory of electricity as developed by M. Blondel and myself shows that these waves actually *are* propagated in the way he considers impossible, *i. e.*, are propagated in an approximately spherical (hemispherical on account of the presence of the earth's surface). In addition, actual quantitative measurements repeated again and again over a period of four or five years, in which all intensities were carefully plotted, show that the mathematical theory as developed by M. Blondel and myself is correct.

What has Mr. Taylor to present against the mathematical theory of M. Blondel and myself and my own quantitative measurements? Nothing but his own bare statements deduced from "logical considerations" and unsupported by the slightest particle of experimental evidence.

I think that any further discussion of Mr. Taylor's theory is unnecessary, until he produces some mathematical foundation for, or experimental confirmation of, his ideas. There are one or two statements, however, in Mr. Taylor's letter which I may touch upon. He states in his letter, second paragraph, that I have accused him of being a "lucky guesser." No such statement occurs in my communication. On the contrary, my communication shows, I believe conclusively, that Mr. Taylor is not a "lucky" but an "unlucky guesser," inasmuch as he assumes that the waves are propagated in an entirely different manner from what theory and experiment shows to be the fact.

He states that I have assumed that he made no experiments. I made no such statement. The assumption I did make was that he had made no *quantitative* measurements. If Mr. Taylor has made any quantitative measurements, he has done himself an injustice in concealing the fact. So far as I know, at the present time there is only one form of receiver in existence which is capable of giving accurate quantitative measurements, and that is the hot-wire barretter. If Mr. Taylor knows of any other piece of apparatus, he should certainly disclose it.

With reference to Mr. Taylor's statements that the curvature of the earth would have little or no effect on transmission, I would say that this is incorrect, as it can be mathematically demonstrated that a wave transmitted from England to the antipodes will lose exactly 50 per cent. in intensity. Mr. McDonald has, I believe, made two calculations on the loss across the Atlantic, and I understand gets somewhat different results from the above, but I believe that my results will be found correct.

With reference to Mr. Taylor's statement, "Ionized air would and does absorb much of the energy from the waves, according to the degree of ionization present," I would say that this is another instance of the inadvisability of attempting to apply "logic" instead of quantitative measurements to natural phenomena. I have a set of accurate quantitative measurements extending over half a year, including thunder storms, droughts, zero and freezing weather, snow storms, rain and fog, and I am prepared to say now that up to date there is no evidence of any such ionization effect. I do not mean that no change in intensity has been observed, but that in every case where change in intensity has been observed it has been found to be *mainly* due to other causes, one being the type of receiver used. I would point out that up to the present time absolutely no evidence has been given that, even if this effect does exist to the extent mentioned, it is due to the effect of ironized air and not to other causes.

With reference to Mr. Taylor's definition of waves, that in all waves the electrical and magnetic energies are equal, I would refer him to Dr. Pupin's paper in the *Transactions* of the American Institute of Electrical Engineers, February, 1901, entitled "Wave Transmission over Cables and Long Lines." I am prepared to believe that Dr. Pupin's definition of a wave is as permissible as that given by Mr. Taylor.

With reference to the question of the phase of the energy in Lodge's waves, I would point out that since the term Lodge waves was introduced by me and defined in the manner stated, any wave which does not have this property cannot be called a Lodge wave.

As regards correctness of this definition Prof. Lodge's own statements may be quoted. For example, on page 5 of his work entitled "Signalling Through Space Without Wires," Third Edition, Sir Oliver Lodge says: "Furthermore, any conductor electrically charged or discharged with sufficient suddenness must emit electrical waves into the ether, because the charge given to it will not settle down instantly, but will surge to and fro several times first; and those surgings or electric oscillations must, according to Maxwell, start waves in the other, because at the end of each half swing they cause electromagnetic effects, and the rapid alternation from one of these modes of energy to the other constitutes etherial waves. If a wire is handy they will run along it, and may be felt a long way off.

"Strictly speaking, in the waves themselves there is no lag or difference of phase between the electric and the magnetic vibrations; the difference exists in emitter or absorber, but not in the transmitting medium. True radiation of energy does not begin till about a quarter wave length from the source and within that distance the initial quarter period difference of phase is obliterated."

In the conductor, therefore, the energy alternates between the electrostatic and the electromagnetic. We know from the mathematical theory of electricity as set forth, for example, by Prof. J. J. Thomson in his "Recent Developments," and also from direct experiments made by myself and others, that if we have a long straight vertical antennæ, the wave length produced by its discharge will be four times the height. In other words, that the disturbance will approximate the velocity of light.

Waves of the type imagined by Mr. Taylor, having a constant height and spreading out in a "circular belt," have no existence and are at variance with the mathematical theory of electricity.

It was on waves of this character, oscillating backward and forward in conductors, that Sir Oliver Lodge made his brilliant investigations.

We have, therefore, three separate and distinct classes of waves, differing fundamentally from one another.

First. The waves investigated by Hertz. These travel in straight lines, and their electromagnetic and electrostatic energies are a maximum at the same instant.

Second. The waves investigated by Lodge. These differ from Hertzian waves in that they do not travel in straight lines, but follow the conductor. They also differ in that, as pointed out by Lodge (Ibid.), the electrostatic energy is a maximum at the time when the electromagnetic energy is a minimum.

Third. The waves investigated by me. These differ from Hertzian waves in that they do not travel in straight lines, but are guided by the surface of the conductor. They differ from Lodge waves in that the electrostatic and electromagnetic energies are a maximum at the same instant.

All these waves travel with approximately the velocity of light, and have their electromagnetic and electrostatic eneergies equal.

It is hoped that the above brief definition of the three broad classes of electromagnetic waves which have up to date been investigated will prove useful in distinguishing between the different types.

A fourth kind of wave observed in some of our experiments may be described as a closed or anchor ring wave. I hope to describe this at some time in the future.

With reference to Mr. Taylor's assumption that my barretter was incapable of detecting currents in the earth, I would point out that in the first place this is pure assumption, unsupported by any evidence, and secondly, that if Mr. Taylor had read Mr. Collins' paper carefully he would have found that as a matter of fact currents *were* observed in the earth. For example, in the fifth paragraph of Mr. Collins' paper he states that "At the point where the direction of the waves changed from along the water to up the slope of the bank currents were generated." Now, in going up the slope of the bank, the detector was shunting a circular belt of the earth's surface in exactly the same way as when the ground was horizontal. Therefore, the statement that the detector was not sensitive enough to show currents when shunting a circular belt of the earth is incorrect, since currents in the earth were actually observed and quantitatively measured.

In addition to the actual fact that currents were actually measured under these conditions, I would point out that if Mr. Taylor will calculate the resistance of the earth he will find that not only was the detector, which responds to 1/50 of an erg. sufficiently sensitive, but also that in practice it is necessary to shunt the hot-wire barretter with a metallic conductor in order to prevent its being destroyed. This matter I will discuss in a separate article, as my statement is to a certain extent conditioned by what is meant by a "current." An effect was produced on this barretter in all cases.

I note that Mr. Taylor states that his measurements on the relative sensitiveness of coherers and magnetic receivers do not agree with mine, and that he finds that there is "a surprising small difference between them."

I might point out that Mr. Taylor has not indicated, as I have done, the method in which he made these measurements, but it will suffice if I quote the following from experiments made by the Marconi engineers, and published in the *Scientific American* on November 28, about a month after my paper appeared:

"The result was that, under such conditions, over a distance of 76 km (47 miles), which is that from San Vito to Leghorn, the Morse apparatus required a 9 mm. (.354-in.) spark in order to receive properly, while with the magnetic detector, receiving was possible and satisfactory with sparks of but 2 mm. (.078 in.)."

Since the energy varies approximately as the square of the spark length, it will be seen that the magnetic hysteresis receiver was approximately 25 times as sensitive as the coherer.

Now, my measurements, given in my letter of October 31, made it about 40 times as sensitive, and in this connection it may be mentioned that I have been informed that the Marconi engineers have not yet been able to design a transformer so as to obtain the best results with the magnetic receiver, while I have.

The fact that the Marconi engineers found that the magnetic receiver is 25 times as sensitive as the coherer and I find it 40 times as sensitive, while Mr. Taylor finds "a surprising small difference," may be taken as an indication of the relative reliability of Mr. Taylor's measurements and those made by us.

It must not be inferred from what I have said above that I have failed to recognize the admirable work done by Mr. Taylor in wireless telegraphy. No one appreciates the value of his labors more than I. But engineers in general do not, I believe, understand the present status of wireless telegraphy, and the fact that it is now upon a strictly quantitative basis. The design of a wireless telegraph plant is now just as much a matter of strict calculation as a design of a dynamo, and in fact it is possible to design a wireless telegraph plant much more accurately than one can design a wire line.

Electrical engineers in general would probably be astonished to know that it would be possible at the present time to fill three or four volumes of the size of S. P. Thompson's "Dynamo Machinery" with nothing but a discussion of the principles governing the design of wireless stations and apparatus. Some day I hope to be able to take up this question, but the amount of labor involved in merely transcribing the results is enormous. The experiments alone are numbered by tens of thousands, and a large safety deposit compartment in Pittsburg is at present occupied by record books filled from brim to brim with the quantitative and qualitative measurements which have been necessary for developing this line of work.

Aside entirely from the question of the point above discussed, is the broad one of whether these waves are a new form of wave. It is true that, as Mr. Taylor points out, in my paper before the American Institute of Electrical Engineers I attribute the broad theory to Heaviside, because, as a matter of course, since these are a particular type of electromagnetic waves, their theory must be a particular case of the general electromagnetic theory. Consider, however, the case of the Hertz waves. The theory of these waves was given by Maxwell. The means of producing these waves was given by Fitzgerald. Maxwell's theory and Fitzgerald's method have been shown to be absolutely correct. Hertz was the first to invent a receiver which would be capable of measuring them, and he was the first to *actually make* such measurements. So far as I am aware nobody has, up to date, found fault with Hertz for describing these waves as a new type. My own case is exactly analogous. The general theory of these waves has been given by Heaviside, the idea of images has been suggested by Delaricci and Blondel. The method of generation was to a certain extent known. I was the first to devise a type of receiver capable of quantitatively measuring these waves and also the first to plot their shape and show the way in which they were propagated.

Until this was done there was no certainty as to the nature of these waves, as is shown, for example, by the fact that Mr. Taylor is still of the opinion that the energy does not fall off as the square of the distance.

I believe, therefore, that I am justified in calling these waves a new type of wave, because they are a new type of wave in exactly the same sense that Hertz waves were a new form of wave at the time that Hertz investigated them.

I would here correct a typographical error in my letter of November 13 on the "Relative Reliability of Wireless and Wire Telegraph Systems." As originally written the statement was made: "A number of interfering stations both in New York and Philadelphia." In setting up the article the compositor substituted for the words "A number" the figures giving the height of the verticals at the stations, and made the article read "There are 135 interfering stations." Though the mistake is, of course, self-evident, I take the opportunity to mention the fact that during the yacht races there were sometimes as many as 12 stations simultaneously operating in the vicinity of New York.

WASHINGTON, D. C. REGINALD A. FESSENDEN.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

DYNAMOS, MOTORS AND TRANSFORMERS.

Single-Phase Commutator Motors.—OSNOS.—The first part of a long article in which he gives a review of the development and method of working of single-phase commutator motors. He says that to Lamme is due the credit of having brought single-phase traction successfully before the public and for having shown that the single-phase commutator motor can be successfully used in practice. The Lamme motor does not represent a novel type of alternating-current motor, but an important improvement in the design of the old series motor. To Thomson is due the invention of the repulsion motor. The author then calls attention to the work of Atkinson, who invented from 1895 to 1898 several commutator motors and had recognized at that time the possibility of regulating the speed in this wide limits without an essential loss of energy. The author then gives a critical and comparative analysis of the various types of commutator motors which have been invented. In each case a diagram is given, together with a reference to the first description of this type and a statement whether this type is patented in Germany or not. He first deals with the series motor in original form, which involves difficulties, first in so far as the oscillating exciting field induces an e.m.f. in the coils which are short-circuited through the brushes, and second, on account of the phase difference. The e.m.f. of commutation is not greater than with direct-current motors. Since the e.m.f. induced by the alternating field in the short-circuited coils is proportional to the number of turns, a decrease of the number of turns per segment also diminishes the short-circuited currents which are due to this alternating field. The phase difference of the series motor is due to the self-induction of the stator and of the armature. The latter can be compensated for by the use of a compensating winding, either in series with the armature (Steinmetz) or short-circuited on itself (Heubach). The shunt motor does not seem to be promising since its power is in general very small. He then discusses various forms of repulsion motors and points out that the frame of the repulsion motor should be formed of uniformly distributed iron masses. For the stator winding a uniformly distributed winding is preferable. In comparing the repulsion motor and the series motor he says that the former has a greater phase difference for the same weight. On the other hand, the repulsion motor has the good quality that the commutator is always short-circuited and has not to transmit any electric energy, so that the commutation will be in this case just as easy as with slip rings. The author then discusses various types of the repulsion motor invented by Atkinson, and shows how some other combinations may be derived from the same. The article is to be concluded.—*Elek. Zeit.*, Jan. 7.

Single-Phase Motors.—LATOUR.—His reply to Eichberg's communication, recently noticed in the Digest, on the priority of invention of the Eichberg-Wintner single-phase traction motor. The claims that Wintner and Eichberg, in their German patent specification, first proposed to return the energy usually dissipated in the rotor circuits of polyphase motors (external resistances) to the supply network, by the use of a commutator on the rotor and a recuperating transformer with a variable ratio of transformation. To obtain the same results in single-phase motors, they adopted the following arrangement: In Fig. 1 the stator is connected by the main terminals *e f* to the single-phase network *AB*, the instantaneous voltage of which is *V sin wt*. The brushes *c d*, placed in line with terminals *e f*, are connected to the recuperating transformer *T*, the transformation ratio of which is varied with the speed of the rotor. The rotor torque is obtained by connecting the auxiliary stator terminals *a b*, placed at 90 degrees to the main terminals, *e f*, to an auxiliary source of current, the voltage of which is in quadrature with the voltage of *AB*. Because Wintner and Eichberg have stated that, as an alternative, the auxiliary source of current may be applied to the rotor by brushes, *a′ b′*, placed in line

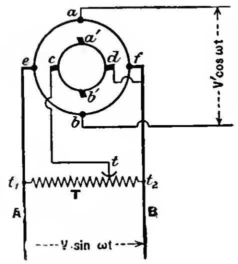


FIG. 1.—SINGLE-PHASE MOTOR CIRCUITS.

with *a b*, the present writer claims that they have failed to understand the essential phenomena of compensation. This argument is that if at, or nearly at, synchronous speed of rotor the brushes *c d* are short-circuited by bringing the contact *t* to the terminal t_2 of the recuperating transformer *T*, while the brushes *a b* are connected to the auxiliary source, the rotor and the stator windings will be burned out and the torque of the motor will completely disappear. This will take place owing to the suppression of self-induction in the rotor. The writer claims that since Winter and Eichberg have become acquainted with his compensated motor they have modified their original ideas and now point out the advantage of zero-phase displacement between the instantaneous voltages of the network *AB* and the auxiliary source.—Lond. *Elec.*, Jan. 8.

REFERENCES.

Electric Motors.—HOBART.—A continuation of his long serial on electric motors, their theory and construction. The present installment deals with the slip and torque of induction motors. Only elementary mathematics is used, but the explanation is very specific, the author giving much numerical data. A table of diagrams gives data of various induction motors.—*Traction and Transmission*, January.

Eddy-Current Losses in Machines.—See the abstract on Eddy Currents under Electrophysics.

LIGHTS AND LIGHTING.

REFERENCE.

Train Lighting.—MARTENS.—The conclusion of his illustrated serial on different methods of electric train lighting. The present insallment gives an illustrated description of a system devised by Kull and employed by Brown, Boveri & Company, in which use is made of a shunt dynamo of special construction, a small storage battery and various controlling apparatus. The system of Vicarino is also described.—*Dingler's Polytechn. Journal*, January 9.

Power.

Pumping Station.—A fully illustrated article on Philadelphia's new fire-fighting service, covering the congested business portion. There is provided a central pumping station and independent pipe system whereby high pressures are obtained directly at the hydrants. The pumping station will contain ten pumps each capable of delivering 1,200 gallons per minute at 40 revolutions, against a pressure of 300 lbs. per sq. in. There are also two pumps of 350 gallons capacity per minute. Each of the large pumps will be driven by a 280-hp, three-cylinder, single-acting gas engine, and the small pumps by gas engines of 125-hp each, which will also drive ignition generators of 7.5-kw each and the air compressors supplying air at 200 lbs. pressure for starting the main engines. There are three sources of current for ignition, connections with the city lighting mains and a storage battery being provided in addition to the ignition generators. The lighting current is reduced from 220 to 110 volts by a rotary converter. The engines are started with compressed air in one cylinder with the relief valves on the pumps open. These valves are controlled by electric motors operated from the engine platform, one motor being on each valve. The entire work of operating the engines, pumps and valves is under the immediate control of one person, who, from the gallery of the engine, without moving from his position, can open and close all valves by means of electric devices.—*Iron Age*, January 21.

Power Absorbed in Drilling.—Norris.—An account of an extended investigation of the power absorbed in drilling in various metals at various speeds and feeds. The results are given in tables and the following general conclusions are arrived at: When the speed and feed are constant, the power required to drill cast steel is about 1.10 times, wrought iron about 1.65 times and machinery steel about 1.90 times, that required to drill cast iron. When the speeds and feeds remain constant, the power required is approximately proportionate to the diameter of the drill. When the diameter of the drill and rate of feed are constant, the power required is approximately proportional to the speed. When the speed and diameter of drill are constant, the power required is approximately proportional to the feed.—*Am. Mach.*, January 14. The numerical data given by the author are represented in form of five diagrams in *Am. Mach.*, January 21.

References.

Milling Machine.—A detailed illustrated description of a universal milling machine of the Brown & Sharpe Manufacturing Company, an essential point of which is that the power-receiving shaft runs at a constant speed and variations of the spindle speed are obtained by means of change gearing. Thus the machine, when motor-driven, enables the use of a constant-speed motor.—*Iron Age*, January 14.

Turbine Tests.—An account of tests of turbines for the Cleveland, Elyria & Western Railway. These turbines are of 1,000 kw, direct-connected to a two-pole, three-phase alternator of 50 cycles. The turbine ran at about 1,500 r.p.m. and had an average overload of 50 per cent. Data from the test are given.—*St. R'y Jour.*, December 19.

Turbo-generators versus Reciprocating Engines.—See the abstract on Eddy Currents under Electrophysics.

Traction.

Alternating-Current Traction.—An abstract of the discussion at the Manchester local section of the (British) Institute of Electrical Engineers on Eborall's paper recently abstracted in the Digest. Portheim read extracts from a letter from Blathy (of Ganz & Co.), comparing three-phase and single-phase motors for economy and efficiency, to the advantage of three-phase. The losses are greater in single-phase, more expensive gear is required for regulation, and they are restricted to a low-pressure system. Regulation with three-phase is effected by the half-speed cascade arrangement. The capital outlay for three-phase and single-phase is the same. He considers it no disadvantage that three-phase motors have to take the worst grades at full speed, and the sub-stations ought to stand the overload. To obtain the same acceleration the cost of three-phase is only equal to direct-current equipment. Regeneration of three-phase on the down grades is an advantage. He remembered making arrangements to supply three-phase traction current to a colliery and when the line came to be operated, with empty trains going up and full ones coming down from the colliery, they found that instead of supplying current to the colliery they were furnishing current to the supply company. Comparing the double trolley with the single, he drew attention to the fact that the same power can be transmitted through the double trolley at a lower voltage, and, any way, the cost of the line can be only 7 per cent. of the cost of the locomotive equipment. He believes it is only 1½ per cent. on the Valtellina Railway. The three-phase motor is as simple as any other motor, and in heavy main-line work the pressure would have to be greater for single-phase than for the two-wire, three-phase line. Rhodes expressed his disbelief in single-phase motors with commutators. The great point about alternating-current motors would have to be the absence of a commutator and freedom from repairs to minor details. Eborall said that there was no hope for single-phase motors starting with phase-splitting arrangements beyond ordinary industrial application. He defended commutators in low-frequency, single-phase motors, but said that in any case a series motor is hopeless over 25 cycles.—Lond. *Elec.*, January 1.

Alternating-Current Traction.—Some editorial notes on Arnold's electropneumatic system. Its success is thought to depend upon the controlling valve mechanism for securing the proper relative action of the electric and compressed air devices. Assuming that this arrangement is perfectly successful—that is, that by its means the air engines geared to the motor may be made to equalize the varying load, torque and speed requirements at all times, without sacrifice of reliability or material drop of efficiency—then the system is believed to promise the best combination of the advantages of the direct-current system and high-tension alternating-current transmission that has yet been proposed. The weight of car equipment is rather high, but applied to a locomotive it will not be a disadvantage. Concerning the use of high voltage it is doubtful whether the public and the responsible authorities will permit high-voltage trolley lines to be installed, if at all, without better guarantee of safety than is afforded by present practice in car wiring and operation. The same contains a communication by Lincoln in which he replies to some criticisms in a former issue on his paper on alternating-current traction. Concerning the use of high voltage he says that practically all of the apparatus on the car may be placed in the low-tension side of the car transformer. The only high tension on the car, therefore, consists of the high-tension winding of the transformer, the current from the trolley to the transformer and a circuit-breaker. These can be protected so as to make the escape of current practically impossible. The part of the apparatus from which the current is most liable to escape, namely, the motors and controlling apparatus, are at voltages which are lower than present direct-current practices. It is a question, therefore, whether or not the alternating-current equipment is not really safer than the present direct-current equipment. Moreover, the trolley voltage can be reduced at will by increasing the number of transformers along the line. The cost of this would not be prohibitive.—*Eng. News*, January 7.

Three-Wire System for Traction.—McMahon.—A long paper read before the (British) Inst. Elec. Eng. on the City & South London Railway, in which he gives the working results of the three-wire system used on this road. Fig. 2 shows the system in its simplest form; that is, all the independent cables for supplying the lifts and lighting circuits being omitted for the sake of clearness. The up and down working conductors, with the running rails as the middle wire, form the three-wire system pure and simple, the 500-volt generators being on either side of the system. To supply the sub-station, another generator, either steam or motor-driven, adds an additional 500 volts to an additional set of high-tension bus-bars, from which the two sub-stations are fed at 1,000 volts above the rail potential, or 2,000 volts across the outers. The pressure is reduced at the sub-station by special reducers, in which only half the energy is transformed and the cable drop compensated for. In the engine house at Stockwell seven direct-connected sets are installed varying in output from 125 kw to 800 kw. The author gives details of an all-day test, discusses electric versus hydraulic lifts in favor of the former, and gives detailed accounts of results obtained in continuous working. The coal per ton-mile at the switchboard amounts to 0.237 pounds, which figure includes all boiler house losses, such as lighting up boilers, etc. If compared with main line locomotives the result is in favor of the latter, but the author calls attention to the fact that the energy spent upon accelerating main line trains is only a fraction of that spent upon a line of short sections, and the traction resistance per ton is at least double that obtained in main line practice. "The published results obtained with steam locomotives are usually taken over short periods and refer to special tests from which all standing losses are excluded. When the time arrives at which electric locomotives can be tried under conditions similar to those of steam locomotives, there is every reason to believe that the coal per ton-mile will be in favor of the electric locomotive." The latest type of powerful locomotives used on this road has been very successful, and it has been found that the slot-wound armature is vastly more satisfactory than the smooth-core armature. In an editorial discussion of the paper special attention is called to the following points: Using direct-current generation with only 2,000 volts maximum pressure (1,000 volts either side from earth), the Angel sub-station, at a distance of 5½ miles, delivers 83 per cent. of the power delivered at the bus-bars. The result is not materially different from the all-day efficiency of a three-

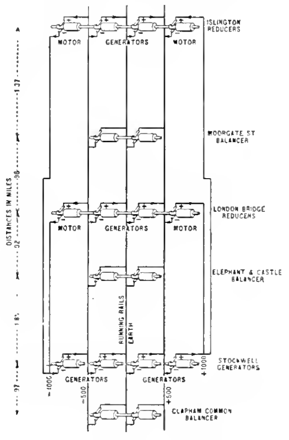

FIG. 2.—THREE-WIRE TRACTION SYSTEM.

phase rotary converter working on a similar load factor, but is attained with a lower working pressure and very much less expensive converting apparatus. The main reason for this is that the current has not to be transformed in kind, consequently the high-tension mains and the transforming apparatus have to deal only with a portion of the current, and transformation losses are incurred upon that portion only. The total result over the whole line is that from generating station switchboard to locomotive, the net efficiency is 90 per cent. This figure is decidedly higher than the all-day efficiency of a rotary converter on a traction road, and the capital expenditure is obviously on the side of the direct current. For such lines as that of the City & South London Railway, a direct-current generating station has an economical radius of at least 6 or 7 miles.—Lond. *Elec.*, December 18, 25.

Electric Traction on Canals.—An illustrated description of the system used in the trials of electric traction on the Teltow Canal in Germany. For most part a locomotive running on the tow path is used, while at special points a vessel provided with a storage battery of 220 cells is used for dragging the boats through the canal. This vessel can also get current from a double overhead wire, either by contact rods of 12 m. length of the kind used for tramways without rails or the Lombard-Gerin system may be used, in which a small motor runs along the trolley wire and is connected with the wires supplying the current to the vessel. For the locomotive also two overhead wires are used, because the return of the current through the rails would have disturbed the magnetic observatory in Potsdam. Otherwise a single trolley would have been sufficient. Some details are given of mechanical arrangements of the locomotive. In a test in which four vessels, representing an aggregate load of 1,450 tons, were dragged with an average speed of 4.35 km. per hour, the tractive force was 2,000 kg. during starting and otherwise, 1,000 kg. in the average. The voltage between the two overhead wires was 445 volts and the average current consumed was 35 amp. The average efficiency was 61.5 per cent. The electric boat is provided with three screws, each being driven by a 20-hp motor running at 600 r.p.m. normal speed. If current is supplied from overhead wires a voltage of 500 to 600 volts is used. If storage batteries are used the voltage impressed on the motors is 400 to 450. For regulating the speed within wide limits the connections of the motors are changed, eight different arrangements being possible. In a test in which the boat had no trailer boats, the speed was 12.5 km. per hour and the current consumed was 85 amp. at 400 volts. If the boat drags two vessels with a total weight of 454 tons, it attains a speed of 5.2 kw per hour and consumes 43 kw. This shows that the efficiency of the boat is not nearly so high as that of the locomotive. The main reason is that the efficiency of a ship's screw with a small diameter is very low. Since only for short stretches of the canal the electric vessel is used, and the locomotive on by far the greatest part, the low efficiency of the electric vessel has only a small influence on the economy of the whole service.—*Elek. Zeit.*, December 31.

Running Trolley Wire.—Harvey.—Since a properly constructed wagon for carrying trolley wire drums and running out the wire is sometimes too expensive in smaller cities, the author has devised a cheap reel frame for this purpose which can be placed and worked on the top of an ordinary two-wheel stiff cart and has most of the advantages of a proper reel wagon. The apparatus is described together with drawings.—Lond. *Elec. Rev.*, January 8.

Insulation of Trolley Wire.—Moerk.—A brief mathematical article illustrated by diagrams in which the author gives an account of insulation measurements of the trolley wire with electric tramways.—*Elek. Zeit.*, January 7.

Installations, Systems and Appliances.

Cut-Outs.—Andrews.—A communication referring to the opinions expressed by various other writers in a discussion on this subject, as was recently noticed in the Digest. The present writer has for 10 years experimented on a great many different types of cut-outs and has reached the following general conclusions: Zero cut-outs are useless. Maximum cut-outs in generator circuits are equally useless. Polarized cut-outs will work satisfactorily on a small or moderate reverse current, but will almost invariably fail on a short circuit, because the heavy series current entirely wipes out the effect of the permanent magnets. The releasing pull of a reverse-current cut-out should increase as the reverse current increases, as it does in an excess current cut-out. This result can only be obtained by employing the series current to directly operate the cut-out. In many types of cut-outs the release pull increases with the reverse current up to a certain point. The curve then doubles back and, with a further increase of current, falls to a zero and reverses to a holding-in pull, thus causing the cut-out to fail. Compound-wound devices will fail if the e.m.f. winding is coupled directly across the terminals of the generator controlled, as a short across the brushes will cause this e.m.f. to fall to zero. If the shunt winding of the cut-out is connected across a battery in parallel with the generator, the resistance of the battery and generator leads will often serve to maintain sufficient e.m.f. across the shunt to operate the cut-out. This, however, cannot be relied upon. To obtain absolute reliability the shunt windings of the cut-outs should be excited off a small independent battery, that will be unaffected by any disturbance on the supply system. Reverse-current cut-outs should not operate with a reverse current of less than 25 per cent. of the full-load current. Cut-outs can quite well be made to operate on a reverse current of less than 5 per cent. of the full-load current, but such cut-outs require fine adjustments and are more liable to give trouble.—Lond. *Elec.*, January 8.

Graphite Rheostat.—Klein.—An illustrated communication referring to the graphite rheostat of Hopfelt mentioned in the Digest October 31. He also has found that graphite powder has special advantages for use in rheostats since the resistance of such powder decreases gradually while current passes through it. This property seems to make such a rheostat suitable for starting motors. However, such a rheostat changes with the time, having a different initial resistance when freshly filled than after having been used for some time. After such a resistance has been used for a while its resistance when current begins to flow is much smaller than when it is freshly filled, so that the valuable property of a considerable decrease of resistance while the current passes is finally lost. This is due to the fact that the powdered graphite has conglomerated into globules, which are better conductors than the powder.—*Elek. Zeit.*, November 26.

Hopfelt.—A reply to Klein. He confirms the observations of the latter, but has found that the conglomeration in globules is due to impurities which are either in the graphite powder or are due to evaporation of the insulating layers and the contact plates with the rheostat. For this reason he now uses specially prepared pure graphite and provides for good radiation of the heat developed in the rheostat. A freshly-filled graphite powder rheostat changes with the time, although unused, slightly compressed powders decreasing in resistance and strongly compressed powders increasing. It is, therefore, necessary to choose such a pressure that there is no change of resistance with the time. He states that several hundred of these rheostats have been used for months and some for a year and a half and none of them has shown a change of resistance.—*Elek. Zeit.*, December 31.

WIRES, WIRING AND CONDUITS.

Perforation Voltage.—BAUR.—An article in which the author gives the results of experimental investigations which confirm the imperical law given by him before. It states that the voltage at which a dielectric is perforated equals a constant multiplied by the ⅔ power of the thickness of the dielectric plate in millimeters. The constant, therefore, represents the e.m.f. in volts which is required to perforate one millimeter of the substance. It is, however, not entirely constant, since it slightly increases with increasing thickness of the dielectric. For air with a sinusoidal current and plate electrodes the constant is about 3,000 volts, while for air with sinusoidal current and needle point electrodes the constant is 2,400 volts. Pointed electrodes, therefore, require a smaller perforation voltage than plate electrodes, as has long been known. He uses this formula to determine the voltage of a lightning flash. If the length of air perforated by the lightning flash is one kilometer, then the voltage is 30,000,000, if the constant is 3,000; but since the constant is greater for a greater distance, the voltage of the flash is estimated as about 40,000,000. For mica the constant is 58,000, for paraffine 20,000.—*Elek. Zeit.*, January 7.

Power Transmission Cables.—SCHMIDT.—A continuation of his illustrated serial on the construction and manufacture of cables. In the present installment some details are given on the construction of cables of Cassirer. Impregnated paper and jute is used either alone or combined. For the high-tension cables with fibre insulation, paper is used, although on the basis of good results in practice, paper is already used in cables with 500-volt pressure. The cables insulated with paper or jute are mainly used for underground power transmission, while the lead-covered cables, insulated with vulcanized rubber, are mostly used in mines and on shipboard. Some details are given as to cables between 250 and 2,000 volts.—*Elek. Anz.*, January 3.

ELECTRO-PHYSICS AND MAGNETISM.

Eddy Currents.—THORNTON.—The conclusion of his illustrated paper. He discusses the influence of periodic irregularity of armature rotation and of unequal turning moment in prime-movers on the magnitude of the eddy currents, and gives the results of some experiments made by him which show that the efficiency of a transmission system supplied from turbo-generators may be several per cent. higher than from reciprocating engines. Two converters in his laboratory were connected single-phase, then driven by direct current, first from a turbo-generator and afterwards from a single-cylinder, double-acting engine with a heavy fly-wheel. Measuring the input and output by carefully calibrated wattmeters, the curves shown in Fig. 3 were determined. The author remarks that the case no doubt represents the two extremes of engine regularity, "but many large gas engine plants show much more fluctuation on load than does a 75-hp, single-cylinder engine." In an appendix the author deals with the separation of eddy current and hysteresis loss in armatures.—Lond. *Elec.*, January 8.

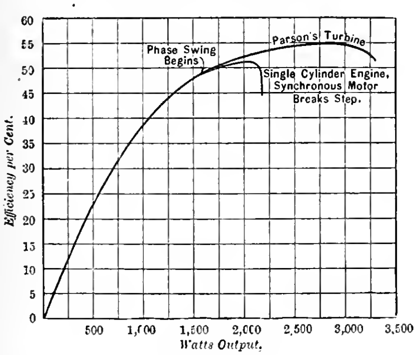

FIG. 3.—CURVES OF TESTS.

Damping of Oscillations.—KOWALSKI.—An abstract of a paper read before the French Society for the Advancement of Science, in which he discusses the reasons of the disagreement between the theoretical formula of Lord Kelvin for the damping of electric oscillations and the experimental results of various physicists. He finds that Kelvin's formula is correct and that the disagreement formerly found is due to the fact that the theoretical conditions of the experiments were not rigorously maintained. Poor insulation of the self-induction coils is the main fault. In fact, the measurement of the damping which can be made with great accuracy, may be used as a good indication of the quality of the insulation. He emphasizes the importance of good insulation for the various applications of electric oscillations.—*L'Eclairage Elec.*, December 12.

REFERENCES.

Dielectric Hysteresis.—BEAULARD.—A paper read before the French Association for the Advancement of Sciences. Schaufelberger has formerly indicated a method for studying dielectric hysteresis, but an error in the calculations has rendered his numerical values inexact. The present author has recalculated the results of these experiments. One of the interesting results at which he arrives is that of the two hypotheses on ether—one assuming the ether at rest and the other assuming the ether to be carried together with moving matter—the latter is the more probable one. It is the fundamental hypothesis of the theory of the electrodynamics of Hertz.—*L'Eclairage Elec.*, December 12.

Quaternions in Electrical Calculations.—FERGUSON.—A brief paper on the use of quaternions in the theory of alternating-current phenomena.—*Phys. Rev.*, November.

Terrestrial Magnetism.—MATHIAS.—An abstract of a paper read before the French Association for the Advancement of Science on the law of regular distribution of the total force of terrestrial magnetism in France on January 1, 1896.—*L'Eclairage Elec.*, December 12.

Nature of Radioactivity.—LODGE.—An abstract of a lecture in which he considers that the phenomenon of radioactivity is intelligible and simple on the theory that it is due to atomic disintegration. The important consequences of the theory are the belief in the mutability of matter and the transmutation of the elements.—Lond. *Elec.*, January 8.

ELECTRO-CHEMISTRY AND BATTERIES.

Electrical Losses in an Electrolytic Copper Refinery.—HUTCHINSON.—An account of the results obtained in the course of an investigation made in 1897 on the cost of producing and using steam power throughout the Anaconda works, and also of determining the cost of electrolytic refining at these works. The energy loss in contacts in the tanks, obviously great, was considered in detail. For one "system," comprising 200 tanks in series, the current was 3,800 amp., the pressure at the generator 67 volts; the losses in switchboard, 0.31 volt; in feeders, 2.00 volts; in mains, 6.00 volts; in all contacts, 7.36 volts; hence, the total volts lost, 15.67, i. e., 23.5 per cent. Thus the electrical efficiency from generator terminals to the solutions was 76.5 per cent. and the total loss from generator to solution was divided as follows: In switchboards, 2.0 per cent.; in feeders, 12.8 per cent.; in mains, 38.4 per cent.; in contacts, 46.8 per cent. For one tank system of 200 tanks the loss thus amounts to 60 kw; this makes the total annual cost of wasted energy for one tank system $9,400, and for six, $56,400. As the capacity of the refinery was approximately 30,000 tons per year, this gives a cost of $1.88 per ton for lost energy. While this amount seems small, it is very approximately equal to the interest on the total investment in the refinery plant; hence, a saving of one-half of this loss would justify an increase of 50 per cent. in the total investment. "As a matter of fact, one-half of this loss can be saved for a very much smaller sum." The author thinks that the fondness of refinery managers for secrecy is absurd, "since there is nothing to conceal," and that undue secrecy and refusal to compare results with others leads to poor results.—*Electrochem. Ind.*, January.

REFERENCES.

Edison Accumulator.—BAINVILLE.—An article criticising some claims made by Hibbert and relating to his tests of the Edison accumulator. He objects to Hibbert's claim that the property of the

Edison accumulator to stand a heavy rate of discharge, although already half discharged, is a characteristic feature of the cell for traction purposes. He claims that a lead accumulator in good condition is equally capable of fulfilling the requirements of electric traction. As the essential features of the Edison battery, he considers its great durability and its rapid recovery of the original e.m.f. after discharges at a high rate. He does not believe, however, that the latter property is as important as it is claimed to be.—*L'Elec.*, January 2.

Electric Discharges Through Gases.—Kowalski.—An abstract of a paper read before the French Association for the Advancement of Science. He describes his experiments on chemical action of high-frequency discharges through mixtures of gases. At a certain frequency the discharge obtains a special character, which depends upon the quantity of electrical energy. He has especially investigated the production of nitrous vapors by means of discharges through air, and the subsequent production of nitric acid. He states that it is possible to get up to 44 grams of nitric acid per kw-hour, and that the price of the kilogram of calcium nitrate would not be more than 13 centimes (about 2½ cents).—*L'Eclairage Elec.*, December 12.

Rare Elements.—Lenher.—The first part of a summary of our present knowledge of what are called the rare elements. The present installment deals with the radioactive elements; the new atmospheric gases, helium, neon, argon, krypton and xenon; lithium, rubidium and calsium; beryllium; gallium, indium, thallium; germanium and titanium.—*Electrochem. Ind.*, January.

Units, Measurements and Instruments.

Flicker Photometer.—Simmance and Abady.—A (British) Phys. Soc'y paper in which the authors describe a flicker photometer, which is capable of balancing and comparing the most violently contrasted tints and which is based on the following principles: The light effects must be in juxtaposition without any apparent division line, and must move, oscillate or rotate so that the point of juncture of the rays of the two lights passes and returns entirely across the vision field. Any hiatus or longer exhibition of one light than the other biases the result. The observation surface or surfaces upon which the light rays fall must be at exactly the same distance from the eye, at exactly the same angle in relation to the line of sight, and must be of pure white, such as is afforded, for example, by clean chalk, plaster of paris, magnesium carbonate or barium sulphate, since any tint affects the accuracy of the results. The photometer itself consists of a wheel of a white material with a specially shaped periphery, which is caused to revolve before an eye-piece by means of a suitable motor. At right angles to the line of sight and parallel with the axis of the revolving wheel, are the two lights undergoing examination, the rays of which fall upon the shaped periphery of the wheel, enabling the effect of such light to be seen in turn through the eye-piece. The discussion which followed the reading of the paper turned mainly on two points: first, whether the instrument measures candle-power, and second, whether it is independent of the Purkinje effect. In his reply, Abady said that if a Bunsen disc is taken and used to compare the candle-powers of two lights of the same color, the grease spot vanishes at a certain point. If a flicker photometer is substituted for the Bunsen disc the flicker disappears at the same point. In both cases candle-power has been measured. Results obtained from the photometer by different observers agree among themselves and also with results obtained from the Bunsen disc photometer. He does not think the Purkinje effect affects the readings of a flicker photometer, because the same values for the ratio between the intensities of two different colored lights are obtained by varying the distances of the light from the instrument within wide limits.—Lond. *Elec.*, December 25.

Direct-Reading Scales for Slide-Wire Bridge.—Buckingham.—A brief article. When a large number of rough measurements are to be made on the slide-wire Wheatstone bridge, it is very convenient to have the scale so divided as to read directly the ratio of the two segments of the wire, thus obviating the necessity of calculating it or looking it up in Obach's table. While such scales are in common use, the author describes a simple geometrical construction for making them.—*Phys. Rev.*, November.

Comparing Low Resistances.—Wenner.—A brief description of a convenient method of comparing low resistances by means of the Wheatstone bridge.—*Phys. Rev.*, November.

Differential Duplex Telegraph System.—An illustrated description of a method devised 20 years ago by McGaurin and recently revived and improved by Janvey of the Australian telegraphic administration. Batteries are used at one end only. The method of producing the changes of line resistance which actuates the relays at the receiving end is described and illustrated in a diagram. It is thought that for short, well-insulated lines or for underground conductors this system may be perfectly reliable. The system was tried with success on a loop of 175 miles in length commencing and terminating in Melbourne.—Lond. *Elec.*, January 1.

Miscellaneous.

Metal and Mineral Productions.—The annual statistical number, giving statistical data on metal and mineral production in 1903, reviews of the markets, etc. The production of aluminum in the United States in 1903 was 7,500,000 pounds, valued at $2,325,000, as compared with 7,300,000 pounds, valued at $2,284,590 in 1901. The production of copper was 670,880,000 pounds, valued at $88,334,770 (against 610,815,384 pounds and $71,072,586 in 1902). The production of gold in the United States in 1903 was 3,600,645 troy ounces, valued at $74,425,340; besides the output of gold from domestic ores, a large quantity of gold is recovered by the refineries each year from foreign ores and bullion, the output from these sources in 1902 being valued at $34,932,211. The total output of desilverized, soft and antimonial lead produced in the United States in 1903, was 289,030 short tons, valued at $24,492,402, and in addition a production of 84,771 tons of lead from foreign ores and bullion. The output of silver from domestic ores was 56,519,793 trop ounces, valued at $30,520,688. The production of zinc was 156,318 short tons, valued at $16,882,344. There was a large increase in the output of banxite, which amounted to 40,700 short tons ($179,080), against 27,322 tons ($121,465), in 1902. The output of carborundum was 4,724,000 pounds ($472,400), against 3,741,500 pounds ($374,150), in 1902.—*Eng. & Min. Jour.*, January 7.

Reference.

American Trade.—Dredge.—The first part of a long statistical article on the development of American trade, with a great many diagrams. The article is more of a general character dealing with the export trade of the United States and referring to electrical engineering only incidentally. A diagram of the exports from the United States of electrical machinery shows a rapidly ascending and nearly straight line from 1898 to 1901 and a slight dropping off from 1901 to 1902. The article is to be concluded.—*Traction and Transmission*, January.

New Books.

Distribution de L'Energie par Courants Polyphases. Par J. Rodet. 2 ieme Edition. Paris: Gauthier-Villars. 562 pages, 213 illustrations. Price, 15 francs.

The volume is one of the best text-books on alternating-current power transmission systems, printed in the French language. It is essentially intended for the use of electrical engineers and electrical enginering students.

The work is divided into nine chapters. The first chapter is preliminary. The second concerns polyphase generators, both synchronous and asynchronous. The third deals with polyphase conductors and conducting systems. The fourth chapter is devoted to the design, construction and principles of operation of transformers and frequency changers. The fifth chapter considers converters. The sixth deals with polyphase motors. The seventh with meters and measuring instruments. The eighth relates to the applications of polyphase currents to electric traction. The ninth and last chapter describes a number of typical polyphase plants and transmission systems in various parts of the world.

The treatment is clear and logical, employing algebra and engineering mathematics. The author has taken pains to deal with the subject broadly, and does not confine himself to French alternating-current practice. In fact, an American student can learn more about American transmission systems in their salient engineering features than he can find in a number of American books on the same subject.

The book would be improved by a subject-index and an author-index at the end. There is only a chapter-index. The work can be strongly recommended to students of electric power transmission.

Electric Heating Equipment of a Modern Hat Factory.

By Max Loewenthal, E.E.

REGARDLESS of many adverse conditions, the electric heating industry has been making history during the last decade at a pace which is a surprise even to those who have witnessed the remarkable rise of other branches of electrical engineering. Largely responsible for this encouraging situation to-day are, first, a better understanding on the part of the manufacturers as to the needs of the consumer and the limitations of his products; secondly, the tendency of central station managers to make rate concessions to consumers using current for domestic or industrial heating, and finally the public's gradual but inevitable recognition of the advantages of electric heating for specific purposes. To the engineer, the application of electric heat to industrial operations is of particular interest, and a number of instances might be cited in support of the statement that cerain industries have been almost revolutionized and their products cheapened and improved after the introduction of electric heat.

Perhaps the most striking example of this is the use of electric heat in modern hat manufacture, where electric irons and other electrically-heated machines are not only rapidly replacing gas-heated devices, but have become almost indispensable factors, and where price competition must be met while the high standard of quality of product must be maintained. One of the first hat concerns in this country to recognize the advantages of electric heat, and back up their faith by a complete installation was the well-known firm of F. Berg & Co., of Orange Valley, N. J., manufacturers of soft felt hats. This firm, established in 1864, equipped their entire plant with electrically-heated apparatus as far back as September 1, 1898, and when their old plant burned down in 1902, they started at once to rebuild the works, rearing on the site of the old buildings the most up-to-date hat factory in this country, while manufacturing was temporarily carried on in the company's Newark establishment.

FIG. 1.—CORNER OF TRIMMING ROOM, SHOWING ELECTRIC CURLING MACHINES.

The new buildings, completed in the past summer, occupy a plot comprising several acres and represent an outlay of more than a quarter of a million dollars. It is claimed to be the only hat factory built according to a definitely conceived plan, housing within three splendid buildings the necessary machinery and men for an output of about 300 dozen hats per day. The two factory buildings are known in the trade as the "back shop," the smaller of the two, where the initial work is done and the "front shop," where the hats are finished. Although we are particularly interested in the "front shop," which contains the electric heating appliances, it might be well, in order to more fully comprehend the exact mission of the devices, to briefly describe the processes gone through in the manufacture of soft felt hats.

The first building to enter, then, is the "back shop," which runs parallel to the "front shop" or main building. It is built of brick, is two stories in height, 150 ft. long, 100 ft. wide and of the mill type of construction. On the first floor is the stock room for the raw fur as it is received from the fur cutters. This fur is first taken to the blowing room on the same floor, where the hair is separated from the fur by means of four blowers. The fur is then taken into the mixing room, where the various grades are mixed by an automatic machine. In the forming department, a definite quantity of this mixture is then placed around a perforated copper cone, which is dipped into hot water and taken to the sizing department on the second floor. Here the hats are "felted" by being soaked in boiling water and kneaded by hand and machines until the embryo hat has shrunk to its normal size. It is then dried and put through a stiffening machine, clear shellac being introduced into the brim of the hat. Thence the hat is sent into the dyeing department on the same floor, where it receives its proper shade, which varies largely with

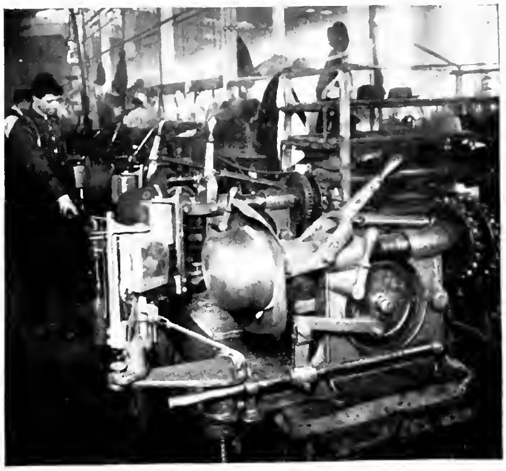

FIG. 2.—PORTION OF MAIN FINISHING ROOM, SHOWING ELECTRIC MACHINE HAT IRONS.

the demand of the market. The shape and size are next given to the hat in the blocking and stretching departments, after which it is thoroughly dried by steam driers and passed down to the pouncing department on the first floor, where it is machine sand papered internally and externally. The hat is then sent to the stock room, from where it is delivered in due time to the finishing department on the top floor of the "front shop." This building, constructed of brick, is three stories in height and has a basement, each floor being 14 ft. high. Its dimensions are 175 x 50 ft. Its roof is a series of skylights, giving the best possible light to the finishing departments on the third floor. The main room on this floor is 100 ft. long by 45 ft. wide, and at the other end of the building is another finishing room measuring 65 x 45 feet. In these two rooms 200 men are employed "finishing," or as it might be more commonly called, "ironing" the hats.

This is done with electrically-heated hand shells, each weighing about 15 pounds and consuming between 400 and 450 watts. The shells are of a uniform shape, which has resulted from many years' use by journeyman hatters. The shells, 200 in number, are equipped with Prometheus electric heating units. The conducting layer of these units consists of a thin metallic film on mica, another piece of mica being used as a cover plate. The two pieces of mica are enclosed in a sheet metal casing and suitable terminals are brought out. A unit of this description is slipped into the hollow shell and pressed against the bottom surface by means of a heavy iron pressure plate, which is forced against the unit by a bolt operating two sliding wedge blocks. A smaller unit is fastened to a projection on the pressure plate and serves to heat the one side of the shell, used for "veluring." For this purpose the shell is inclined on projections on the iron stand and the operator heats a cloth pad held in his hand on this side of the shell. These heating units not alone insure uniformity of temperature, but may be replaced in case of necessity by the workman himself. An idea of the flexibility of this system may be gained from the fact that all the old shells which had gone through the fire were in a very short space of time equipped with the heating units.

Fig. 3 shows one of the hand shell operators at work and, as will be seen, each shell is connected to a separate small knife switch on the wall. The operator's work consists in stretching the hat over a wooden block of the right shape and size, first making it pliable over steam and removing superfluous hair by holding the hat in a singeing stove, and then finishing or ironing the same and trimming the brim to the proper width by means of a gauged knife.

At the further end of this floor twenty-eight ironing machines are located, divided into four gangs of seven each, belted to a countershaft driven by a motor. A gang of these machines, shown in Fig. 2, is looked after by a boy and all his work consists of is to "feed" the blocks with hats and start and stop the shell which travels around the hat, regardless of the shape, the tension being maintained by means of its suspended weight. These machine shells differ from the hand shells in that their faces are slightly curved, while the hand shell faces are perfectly flat, and instead of a handle they are supplied with a shaft at one end, which fits into and revolves in a bearing fastened to an arm, which carries the shell around the surface of the hat. The working face of these shells only is heated and a Prometheus heating unit is held against the easily-removable bottom by means of a heavy pressure plate fastened down by screws. A flexible connecting cord leads from two terminals at the lower end of the shell to a cut-out block at the side of each machine. The watt consumption of these shelves is the same as that of the hand shells.

The many advantages of electrically-heated shells over gas-heated shells, namely safety, cleanliness, better sanitary conditions, reduced operating expenses and lower insurance rates are supplemented in the case of machine shells by the fact that no matter how much the electrically-heated shell may be jarred, the heat supplied is constant and steady, which greatly enhances the efficiency of the operator tending a group of these machines.

From the finishing departments the hats are sent to the floor below where they are passed upon by an inspector and then to the curling machines shown in Fig. 1. In these an electrically-heated revolving disc curls the edge of the brim, the heaters almost entirely surrounding the disc. It needs no argument to show the decided advantage

FIG. 3.—CORNER IN MAIN FINISHING ROOM, SHOWING MANNER OF USING ELECTRIC HAND IRON.

of this method of heating the disc over the old method of projecting against it, and almost into the face of the operator, a jet of gas.

In a large room at the other end of this floor 200 girl operatives sew the various trimmings on the hats, all the sewing machines being electrically driven. In the flanging room on the first floor twenty flanging bags are used for giving the brim its final shape. These bags, which are filled with sand, are at present heated externally on steam tables, but they will probably be heated internally by means of electric heaters in the near future. Fifteen additional electric hand irons are used by the flanging bag operators, shown at work in Fig. 4.

The power house, a pretentious brick structure, occupying a plot 50 ft. by 95 ft., on the company's spacious site, is divided by a heavy fire wall in two sections. In the one are located four Coatesville horizontal tubular boilers, 200 hp each, equipped with the Parsons patent forced draught system, in which superheated steam mixes with the air in the ash pit. Natural draft is obtained from a steel stack 100 ft. high and 6 ft. in diameter. Green economizers and Berryman heaters are used for the heating of the boiler feed water. Three Worthington pumps furnish the water for the boiler and house supply. In the spacious engine room two Fitchburg horizontal, tandem compound, 300-hp engines are direct-connected to two Stanley 200-kw inductor type 60-cycle, 7,200 alternations, two-phase generators, delivering current at 220 volts, and being supplied with automatic phase regulator windings.

One 12-kw and one 24-kw Northern exciter are belted, respectively, to the two generators. The switchboard, consisting of five blue Vermont marble panels, is 17 ft. long and 9 ft. high and is so located that it may be easily seen from any part of the engine room. One of the end panels is used as the exciter panel and is equipped with two ammeters and one voltmeter, of the Stanley type and exciter switches. Adjoining this panel are two generator panels with the usual equipment, the next is the light and heat panel and finally the power panel. In a separate building adjoining the power plant a 100,000-gallon pump is housed which furnishes the water supply for the extensive

FIG. 4.—FLANGING ROOM, SHOWING FLANGING BAGS AND ELECTRIC HAND IRONS.

sprinkler system installed throughout the buildings, there being a total of 1,200 sprinkler heads. The average load on the system is 900 amp. at 220 volts, which is the pressure employed for the operation of the motors, of which there are 30, ranging in capacity from 3 to 30 hp; 800 lights are scattered throughout the buildings and they, as well as the heating appliances, are operated on 110-volt circuits. That these devices are important factors in the operation of a modern hat factory may be gathered from the fact that one-half of the entire average output of the plant described above is consumed by electrically-heated devices, approximating 100 kw.

The designers and owners of this establishment, where steam and gas have been so largely supplanted by electricity, must certainly have been convinced of the truth of the statement, made recently by a well-known engineer, that "An electrically-driven, electrically-heated and electrically-lighted tool is as perfect a combination for good work as it is possible to make." The entire plant was designed and erected under the personal supervision of Mr. Luther D. Martin, of the Taylor-Martin Engineering Co., Newark, N. J., who was retained as consulting engineer by F. Berg & Co., in view of his experience in the design of hat factories. The electric heating equipment was supplied by the Prometheus Electric Company, of New York.

Heavy Traction in England.

A contract for the equipment of a large three-phase electrical generating station to be erected by the Great Western Railway Company at Park Royal, near London, has been secured by the Electric Construction Co., of London and Wolverhampton. The station will require about 10,000 hp of plant, available for either lighting or traction. The North Eastern Railway Company has recently carried out extended and satisfactory trials of the newly electrified branch of their line between Newcastle and Monk Seaton Station, on the other side of Tynemouth. The distance is about 10 miles, with a double track, making the length of rails traversed rather over 20 miles. Mr. Philip Dawson is understood to have been at work for some time on electric traction projects for the London, Brighton & South Coast system.

Central Station Feeder Regulators.

The accompanying illustrations show a type of central station feeder regulator made by the General Electric Company for alternating-current circuits, which is free from the objection of introducing lagging currents. The regulator is of the transformer type, having its primary connected across the bus-bar and its secondary wound in several sections controlled by a dial switch. The amount by which

FIG. I.—REGULATOR

the generator voltage is raised or depressed on the feeder is determined by the amount of secondary winding included in the feeder circuit. The windings of the regulator, being arranged similarly to those of the usual transformer, are free from all appreciable reactance, and the regulator does not, therefore, introduce a lagging current into the system, as is the case with apparatus which contain a large amount of reactance, the presence of which is a necessary consequence of the principle of regulation.

The control of the feeder by means of this regulator is of the simplest nature. Starting with the regulator in position of maximum boost, that is, with the dial switch turned to the extreme left as far as it will go, a continuous right-handed movement of the dial switch

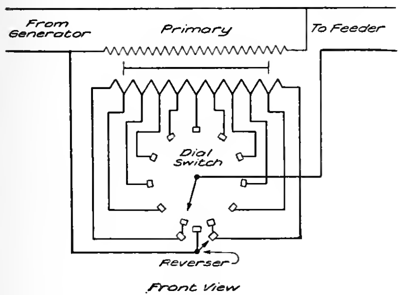

FIG. 2.—DIAGRAM OF SWITCH CONNECTIONS.

for two complete revolutions is obtained. During the first revolution the switch cuts out, step by step, the ten sections of secondary winding. When the first revolution has been completed, the voltage on the feeder is the same as that of the generator, no secondary winding being included. A further movement of the switch in the same direction automatically throws a reversing switch on the back of the panel, and continuing the movement of the dial switch, still in the same direction, the secondary windings are again switched in, step by step, this time with reversed polarity; so that when the second revolution is complete the whole secondary winding is again included in the feeder, but now opposing the voltage of the generator.

Thus by one continuous movement of the switch, covering two revolutions in one direction, the complete range between maximum boost and maximum depression of the feeder voltage is covered. At either end of this range the switch is automatically arrested, so that it is impossible to turn it too far.

The dial switch embodies a number of improvements, designed to overcome objections in other forms of apparatus intended for a similar purpose. In the dial switch, the awkward combination of split contact fingers and reactive shunt is avoided and the switch operates with a positive "snap" movement from step to step, regardless of the manner in which the operating handle is manipulated. This is accomplished by means of compression springs interposed between operating handle and the traveling blade.

An automatic bolt holds the switch on its contact point until the bolt is withdrawn by a self-acting cam, when the spring has received

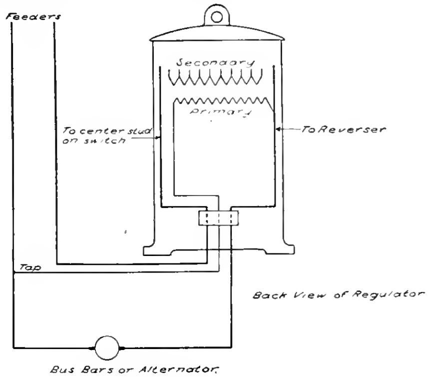

FIG. 3.—REGULATOR CONNECTIONS.

sufficient compression to carry the blade with a quick movement onto the next contact, on which it is instantly locked again by the bolt. Owing to the quickness of movement obtained, together with the special shaping of the contact blades, no flicker on the lamps is observed when the switch is moved from step to step.

The contact blades are of heavy copper with turned edges arranged to chill, by their mass, the momentary arc which occurs when passing from point to point; thus avoiding damage from arcing. If after prolonged service it should become desirable to renew these contact blades, they can be readily removed and replaced.

Fig. 1 shows the appearance of the standard regulator as usually installed at the station and in some special cases at the center of distribution. The core is of the cylindrical type and with its winding stands vertically within a well ventilated frame with sheet iron panels.

Fig. 2 shows the general arrangement for connecting the various sections of the secondary winding to the dial switch; also the electrical connection of the reversing switch. This latter is operated by an arm attached to the main shaft.

Fig. 3 shows the connection of the regulator to the generator and feeders. It will be seen that three leads only have to be connected in order to place the regulator in service.

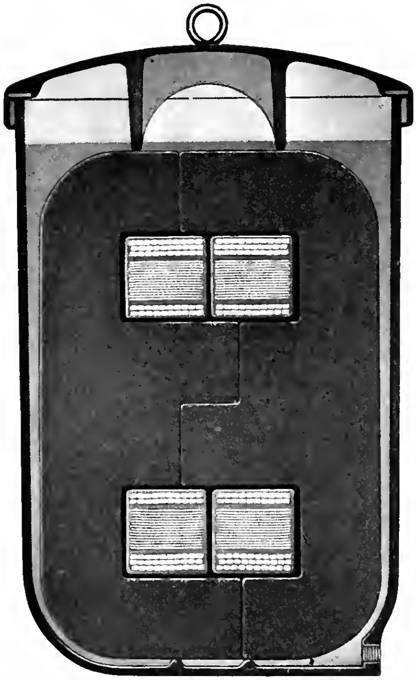
Fire Losses.

It is of much interest to electrical people to note that the property losses in the United States and Canada through fires the past year are estimated to have reached an aggregate of about $152,000,000, allowing for a probable loss of $13,000,000 in the month of December, whose figures are yet to be tabulated. On this showing there was a decline of fully $9,000,000 in the total fire waste as compared with 1902, which showed losses of $161,000,000. The real extent of the gain to underwriters becomes more evident when 1901, with its aggregate of $169,500,000 in losses, and 1900, with its loss record of about $178,000,000, are recalled. Thus 1903 has yielded a fire waste of about $26,000,000 less than that of 1900. There does not appear, however, to be any abatement in the demands of Fire Underwriters for increased precaution at the expense of the insured, nor any sign of reduction of rates.

Practical Study of Transformer Design.

The fact that technical literature used in our colleges can be effectively supplemented by the assistance of manufacturing concerns was strikingly illustrated recently in a transaction between the University of Iowa and the Fort Wayne Electric Works, Fort Wayne, Ind. In class room work an instructor is often handicapped in lecturing on electrical design by lack of suitable illustrating matter on the subject under discussion. This applies particularly to modern standard practice, which is often lacking in up-to-date technical text-books. To supply this omission at the University of Iowa, correspondence was opened by Prof. Spinney with the Fort Wayne Electric Works, regarding the possibility of effectively illustrating transformer construction. The type A oil-insulated Wood transformer was selected as a suitable preferred design for illustrating shell type construction as applied to lighting transformers.

In order to obtain the most satisfactory results in class room work, a full-sized model of the cross-section of the transformer was constructed and mounted in a suitable glass-covered case for suspending on the class room walls. An illustration of this cross-section model is shown herewith. It will be noticed that nearly all of the points of construction which would be considered in economical commercial design are effectively shown in this illustration.



CROSS-SECTION OF MODEL TRANSFORMER.

The cross-section was taken across the coils through the center of the core. In constructing this model a thin section of coils and core was mounted on a board cut to conform with the outlines of such transformers. Around the edge of this board was built up a reproduction of the section of the transformer case the same thickness as the section of core and coils. Felt gaskets under the cover, oil within the case and other features hard to reproduce were represented by the proper color paint. The dimensions of all parts and proportion of different parts were made exactly the same as in a transformer of this size, to show the high insulation between primary and secondary coils and core. In this way also was shown the close proximity of the core to the case and the short conducting path through oil, which is interposed between the core and case on all sides.

Another feature shown is the method adopted in the design of the transformer to make it suitable for operation on three-wire circuits, by dividing the primary and secondary coils into several sections separated from each other by insulating materials and oil space and occupying different positions with respect to the magnetic circuit. The protection to the primary from both moisture and injury is also illustrated, the coarse wire of the secondary surrounding the fine primary conductors on the two sides most liable to injury. The core construction is also plainly seen to consist of a single punching, which is used in pairs to make a single complete lamination in the core.

The magnetic circuits are short and of low reluctance, because of the large area of contact between the two sides of the gaps in the magnetic path. The transformer requires a minimum amount of oil for insulation and conduction, because of the close conformity of the shape of the case to that of the assembled core and coils and the most efficient use made of the relatively small amount. Mechanical construction of the case furnishes means for holding the core rigidly in the proper position in the case without the use of angle irons or bracket construction of frame.

The use of the vacuum drying and substitution process employed in the construction of the coils is shown by the uniform spacing and straight regular arrangement of the conductors in different layers of the primary and secondary.

Telephone Card Index Bracket.

Mr. M. Holtz, the secretary of the *Dry Goods Economist,* a well-known trade paper, has recently, by reason of the constant annoyance and delay incurred in looking up names and numbers in the New York telephone directory, invented a very practical attachment for the purpose of giving the subscriber means of instant reference to a name and number. It consists of a nickel bracket attached to the post of the portable telephone above the receiver hook with a slotted bracket containing cards arranged as in a card index permitting any classification by business, alphabetically or any other way that suits the convenience of the user. A card may be withdrawn and any number of names of the same general classification up to the capacity of the card may be seen at a glance and the card will drop back in its place by its own weight. The projecting tabs on the top of the cards give an instant guide to the contents and permit of ready withdrawal of any card or cards.

TELEPHONE CARD INDEX BRACKET.

One great advantage of this attachment is in its permanent attachment to a portable desk telephone which is being constantly shifted around from one place to another, where wall card index books or other separate devices lose their value by reason of not being handy when wanted. This is entirely obviated in the case of this attachment. This invention should also make possible a great saving on the part of telephone companies. The cost of revising and publishing directories is a very large item. With the general use of this attachment by a local company the average subscriber would have little occasion to look in the telephone book.

It will be readily seen that the first card is instantly visible to the user of the telephone—this card being reserved for most frequent calls. Furthermore, its use will permit an exchange operator to repeat back a wrong or changed number call and requesting it be changed on the card, avoiding a recurrence of the same error.

Electricity in Typesetting and Printing.

A considerable amount of space has been given lately to illustrating and describing in the pages of Electrical World and Engineer the various processes dependent upon electricity in some form and employed in the Government Printing Office at Washington. The multiplicity of such processes was bewildering and many readers in commenting upon them have expressed the belief that the list was exhausted. This, however, is not likely to be the

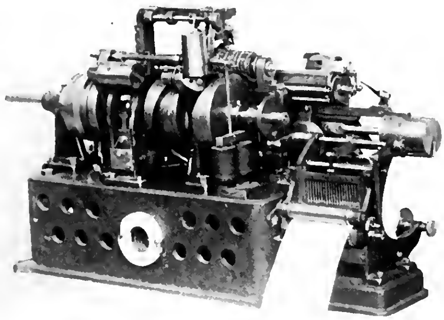


FIG. 1.—PART OF TRANSFER PRINTING MECHANISM.

case for a long time to come; and we are now able to signalize a further departure, to which we have in fact already directed attention. The device is known as the "lithotype" and provides not only for typesetting electrically, but for printing with smooth aluminum plates on rotary presses; so that, in a broad sense the principles of lithography may be said to be applied. The invention is striking also for what it eliminates from the ordinary printing office mechanism and equipment, since it proposes not only to do away with the setting and distribution of type, whether by hand or machine, but does away also at one sweep with matrix making, stereotyping or electrotyping. The inventor is Mr. Walter S. Timmis, consulting engineer of the Sackett & Wilhelms Company, to whom several

Fig. 2.—General View of the "Lithotype" Punching Mechanism.

patents are issuing; while the introduction of the aluminum plate is to the credit of Mr. John Mullaly, president of the United States Aluminum Printing Plate Company.

The apparatus was seen in full operation in New York last week by a member of the staff of this journal. As then studied, the lithotype consists of two parts or devices operating separately. Arrangements, however, have been made to co-ordinate these parts. The first, shown in Fig. 2, and seen operated by a young woman, consists of a small machine comprising an electrical keyboard similar to that of the ordinary typewriter, a perforating device to perforate a stout manila paper ribbon or strip of any required length, and a counting device. The perforating device is operated electrically by electromagnets grouped back and under the mechanism so as to give control by armature pull of the punches making the perforations, and controlled by the depression of the keys through the circuit-closing devices associated therewith. The machine automatically takes care of the spaces between the words. The holes in the strip when it is put on the next machine in the process are translated duly into the letters actuated originally on the typewriter keyboard. The magnets can be run on an ordinary light or power circuit, preferably with a condenser in circuit to avoid "arcing."

The perforated strip goes directly into the second part of the combination, shown in Fig. 1, which operates to bring the printing member into position, so that the selected character is directly opposite the printing point. The character is then inked, the paper is moved up to the character and the impression is taken therefrom. This action is repeated for each character until the line is completed, when the paper-carrying device returns and moves for the new line. Power is furnished conveniently to keep the machine running by a small electric motor. The transfer thus obtained is now ready to be impressed on the surface of the prepared aluminum plate.

The plate, with the imposed transfer, is put under pressure, the paper is washed off, the impression thus made is "rolled up," and then, with a few finishing touches, is ready for the press.

High Pressure Gas Distribution by Gas Power.

A gas-power installation of exceptional interest is now under construction by the Laclede Gas Light Company, of St. Louis, Mo. The system has for its object more efficient distribution of gas over larger areas than may be economically covered by the simple method of running large low-pressure mains from a centrally-located gas-generating plant to supply all parts of the city. The system under construction is intended to supply the entire city of St. Louis, embracing an area of approximately 65 square miles. In order to serve the outlying districts of such an area, one of three methods must be employed: First, large low-pressure feeder from central holder to center of district to be covered; second, medium-sized feeders from main holder to auxiliary holder in center of district, and third, high-pressure feeder to distributing center, using pressure-reducing valves at this point for obtaining proper pressure upon the service lines. The enormous expense for construction entailed by the first two methods has practically prohibited their use in St. Louis, and the high-pressure system is being installed. With this system, the size of feeder pipes is greatly reduced, and the necessity of auxiliary district holders is entirely done away with.

For serving suburban communities, lying far beyond the city limits, this method may be extended and the pressure of the gas raised to any desirable extent for transmission through small pipes, this pressure being reduced at the suburban distributing center by pressure regulators, as in the medium-pressure system above mentioned. This gas-distribution system as a whole presents a striking similarity to the ordinary alternating-current distribution system with primary high-pressure feeders, reducing transformers and secondary low-pressure distributing lines, the theory of high-pressure transmission being in both cases identical.

The pressures to be employed in the system under construction at St. Louis are approximately 5 lbs. per square inch for the medium-pressure feeders and from 20 to 80 lbs. per square inch for the high-pressure suburban feeders. On account of the use of cast-iron mains, the 5-lb. limit was chosen for the medium-pressure system, but for the high-pressure system iron pipe with screwed fittings will be used. With this construction any desirable pressure may be carried with entire safety, and the radius of distribution extended to 100 miles, if necessary.

The gas pressure will be supplied by a blowing unit, consisting of a standard Connersville blower direct-driven by a 300-hp Westinghouse horizontal gas engine of the type recently brought out for high-power work. The engine has two double-acting cylinders, 16½ in. in diameter and 24 in. stroke, arranged in tandem with a single crank, and uses for fuel the ordinary illuminating gas drawn directly from the gas mains. The engine operates upon the four-stroke cycle, and the method of governing secures a constant quality of explosive mixture at all loads, the quantity of the mixture being proportioned by the governor to the load of the engine. Electric ignition is employed. In this particular installation the engine is controlled by an automatic pressure-governor which adjusts the speed of the unit in direct proportion to the demand for gas, the speed thus being in inverse proportion to the pressure in the distribution main. So sensitive is this control that the variation in pressure will not exceed 8 oz. for a 50 per cent. range in gas output. The regular centrifugal speed-governor is, however, also used in order to prevent, under any conditions, the engine running at excessive speed.

The St. Louis installation is one of the first of its kind in the illuminating-gas field and presents many interesting features which will be subsequently brought out in special articles at the completion of the work. The system has, however, long been in successful use in the distribution of natural gas over large districts adjacent to natural gas fields. The St. Louis system is in charge of Mr. W. A. Baehr, engineer of the Laclede Gas Light Company.

Northwestern Electrical Convention Notes.

The exhibits at the Northwestern Electrical Association's winter convention at Milwaukee this year, although not extensive, included some apparatus of much interest to central station men. Nearly all the parlors on the second floor of Hotel Pfister were occupied by the supply men as exhibition and reception rooms.

THE GENERAL ELECTRIC COMPANY made no attempt at a display, but had headquarters in one of the parlors. Its interests were well looked after by Mr. F. N. Boyer, manager of the supply department; Mr. J. Scribner, manager of the lighting department; Thomas Ferris, Wisconsin representative; S. F. Dibble, manager small motor department; W. J. Ferris, of the Chicago office, and James Lyman, engineer Chicago office, who read a most interesting paper on steam turbines before the convention.

THE HOLOPHANE GLASS COMPANY was well represented by its Western distributors, the V. R. Lansingh Co., of Chicago. With its well-known generosity the company presented to its visitors two samples of its Holophane globes and Pagoda reflectors, which retail for $1.15. The news of this, the most expensive souvenirs presented at the convention, soon spread and the already crowded rooms of the company were soon filled to overflowing. The crowd, however, was well handled by V. R. Lansingh and H. M. Lauritzen and each man, after seeing the dark room tests, was presented with the globes. One of the most interesting of the tests in the dark room was that of a 50-cp power lamp on one side and a 6-cp lamp covered with a reflector on the other, the latter showing at least double downward illumination. Another of this company's exhibits was a large board over the doorway fitted with colored lamps with Holophanes and Pagodas, which was connected with a Reynolds flasher. This gave beautiful and startling effects, as the colors were rapidly shifted. The room was beautifully lighted by a new six-light cluster, using a special Benjamin body and six pagodas. Every corner of the room was so evenly lighted that the management of the hotel at once placed an order for 60 of the clusters to light its sample rooms. The best display of this company, however, was the Pfister Hotel itself. The entire lobby, first floor and banquet hall, were equipped with Holophanes over a year ago, every 16-cp lamp being replaced by 10-cp lamps, giving at the same time a marked increase in illumination with the well-known softening and diffusing effect of the Holophane system. So satisfactory has this proved that the management placed their order during the convention for equipping the dining-rooms, corridors, etc.

JULIUS ANDRAE & SONS CO., of Milwaukee, had an extensive display of the various electrical supplies for which it is agent, looked after by J. C. Schmidtbauer, sales manager; F. T. Andrae, vice-president and A. E. Stadlbauer, salesman.

THE CROUSE-HINDS ELECTRIC COMPANY, represented by F. F. Skeel, Western sales manager, of Chicago, exhibited a line of its switches, tablet boards and Norbitt specialties. Their new Imperial car headlight attracted especial attention.

THE DUNCAN ELECTRIC MANUFACTURING COMPANY, of Lafayette, Ind., exhibited a number of its latest type of direct-current meters. Particular attention was drawn to the new method of compensating for friction which consists of a very neat and small multipoint switch placed within the meter and having its contacts connected with various turns of the compensating coil. By the mere movement of the switch lever any desired compensation for friction or vibration can be obtained in an instant. This new feature eliminates entirely the old and clumsy method of moving the compensating coil bodily to effect the compensation. It is also free from the objection of having the compensating coil disturbed or changed by the action of the series coils on short circuit. Another commendable feature is the new visual bearing, which permits of an inspection of the bearings while the meter is in operation, besides allowing the spindle point to be removed for renewals or examination with a special tool. A marked improvement is noticeable in the threadless jewel post by virtue of its simplicity and the quickness with which it can be taken out and replaced again. The binding posts are made both dust and fire-proof, and the spindle is constructed from nickel-steel tubing. The company was represented by Mr. Thomas Duncan and William Cothrell, of the engineering staff.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY received visitors and distributed bulletins in one of the parlors. A number of its well-known meters were arranged for the inspection of the members attending the convention. Messrs. A. L. Millard, W. E. McDonald and Norman Stewart were in attendance and extolled the virtues of the Westinghouse apparatus.

THE SAWYER-MAN ELECTRIC COMPANY did not make any exhibit, but was represented in the person of Mr. C. A. Ross, of its sales staff.

THE NATIONAL ELECTRIC COMPANY sent a cordial invitation to all the members of the Northwestern Electrical Association to visit its plant at Park Place and the river and inspect the manufacture of National Electric machinery and Christensen air brakes. A trip to the factory disclosed the various types of direct and alternating-current machines of the most modern type, in course of construction. A guide accompanied the visitors throughout the shops and explained the various processes of manufacture. The invitation also contained several car tickets of the Milwaukee Electric Railway & Light Company, and directions for readily reaching the plant. At the Pfister Hotel the company occupied a parlor in which several small motors, armatures, coils and apparatus were shown. Several large photographs served to show the larger apparatus which the company has turned out in the past. The interests of the company were taken care of by H. M. Klingenfeld, advertising agent; C. G. Burton, Chicago manager electrical sales; A. P. Peck, salesman; C. P. Tolman, A. E. Knight, engineers, and W. L. Waters, chief engineer, who read a paper before the convention on "Double-Current Generators."

THE BRYAN-MARSH COMPANY had George C. Keech, general manager of Chicago; L. P. Sawyer, manager the Minneapolis branch; J. L. Barnard, Wisconsin representative, and J. S. Corby, Illinois representative, receiving delegates at its headquarters.

THE PHELPS COMPANY had its interests in charge of W. E. Phelps, who exhibited a line of the Phelps specialties.

THE PARDRIDGE REFLECTOR was very much in evidence in the Convention Hall and in the corridors of the hotel. Cards about the hotels called attention to the fact that they increase the light 500 per cent. in a given direction and fit in places where others will not get. They need no shade holder and fit on any lamp from 2 to 50 cp in sizes. Mr. A. J. Pardridge did not fail to acquaint the various delegates with the merits of his invention.

THE WAGNER ELECTRIC MANUFACTURING COMPANY and the BULLOCK ELECTRIC MANUFACTURING COMPANY showed a line of their alternating and direct-current motors in one of the parlors. Mr. E. S. Bissell, assistant manager of sales at St. Louis, represented the former, while L. G. Bassett and H. J. Meyer represented the latter.

THE STANDARD UNDERGROUND CABLE COMPANY, although not represented, as usual, by Mr. Wiley, nevertheless was well taken care of by Mr. E. J. Pietzcker.

THE KUHLMAN ELECTRIC COMPANY, of Elkhardt, Ind., although not making an exhibit, nevertheless was very much in evidence in the person of Mr. E. Kuhlman.

MR. F. L. MERRILL, of the Standard Railway Materials Company, of Chicago, renewed old acquaintances at the convention.

THE BROWNING COMPANY, of Milwaukee, made an exhibit of its new line of motors, which range in size from 3 to 30 hp. They were represented by Mr. William Stark Smith, sales manager; Franklin Sweet, mechanical engineer, and F. W. Ells, electrical engineer.

THE CENTRAL ELECTRIC COMPANY, of Chicago, although occupying one of the larger parlors, contented itself with renewing acquaintances and keeping in evidence in the persons of J. W. Mason, sales manager, and W. W. Geisse, their Wisconsin salesman.

MR. WILLIAM M. PORTER, as Western sales manager, represented the Alphaduct Manufacturing Company. Pipe souvenirs, made of alphaduct, were distributed to the visitors.

THE KESTER ELECTRIC MANUFACTURING COMPANY showed a line of their self-fluxing solder. Mr. F. G. Dickerson, secretary; A. J. Witherall, president, and J. E. Goodwin, salesman, extolled the merits of the company's products.

MR. W. H. SCHOTT, the well-known heating engineer of Chicago, received his many friends in one of the parlors.

THE FORT WAYNE ELECTRIC WORKS made an exhibit of its direct and alternating-current arc lamps and the type "K" meters. Their standard bulletins and literature were distributed among visitors at their parlors. The latter were received by W. S. Goll, the Chicago manager; C. E. Sedgwick and J. S. Raymond, of the Chicago office.

THE NERNST LAMP and its excellent qualities, although not requiring specially to be brought to the attention of the delegates, nevertheless were explained in an interesting manner by Mr. G. E. Bennett, the assistant manager of the Chicago office. A new throw-away holder, which is practically fool-proof, was brought to the attention of the visitors at the parlors. This overcomes any objections which may have been raised in the past against the former method of renewing both the glowers and heaters.

THE WALKER ELECTRIC COMPANY, of Philadelphia, showed a line of its well-known type of switches. The exhibit was in charge of Mr. J. R. Kimball.

THE MILWAUKEE ELECTRIC COMPANY had an exhibit of its well-known line of motors in one of the parlors. Mr. W. Cary, the vice-president of the company and manager of sales, was ably assisted by Mr. I. B. Cary, of the sales department, and T. G. Whaling, the secretary and assistant treasurer.

THE TRIUMPH ELECTRIC COMPANY was represented at the convention by Mr. Jacobs.

THE AMERICAN CIRCULAR LOOM COMPANY exhibited its well-known product and was represented by Mr. Thomas G. Grier, its Western manager.

THE THOMAS G. GRIER COMPANY, of Chicago, made an extensive display of the various specialties which it sells. These included the Kinsman reflectors, Wotton gongs, Hubbell specialties and Wirt rheostats and theatre dimmers. Mr. Thomas Grier, the president of the company, and George A. Gray, sales manager, were in charge of the company's interests.

THE HALLER MACHINE COMPANY, of Chicago, displayed a new line of metal electric signs and dimmers for flashing signs. Mr. William Goltz, the secretary and treasurer, and W. E. St. Clair, superintendent of shops, explained the good points of their apparatus.

THE ELECTRIC STORAGE BATTERY COMPANY was represented by Mr. G. H. Atkin, manager of the Chicago office, and J. M. S. Waring, engineer of the Chicago office, who read a paper on "The Storage Battery in Small Central Stations."

THE ELIOT ADDRESSING MACHINE COMPANY, of Boston, exhibited its machines for printing addresses on bills, papers, etc. The advantages of such a method and of the machines were presented to the delegates in an able manner by R. St. John and A. R. Baker.

Other companies represented at the convention, but not making exhibits were the George Cutter Company, George Cutter, president; the Simplex Electrical Company, W. F. Hruby; the Cutler-Hammer Company, H. H. Cutler, vice-president, and A. Beresford; General Incandescent Arc Light Company, Francis Raymond; American Electrical Works, F. E. Donohoe; Viscosity Oil Company, J. S. Blackford.

Stilwell-Bierce and Smith-Vaile Company's Affairs.

The bankruptcy proceedings instituted against the Stilwell-Bierce & Smith-Vaile Company, of Dayton, Ohio, one of the largest builders of water turbines, pumps, etc., in this country, will not interfere with the operation of the plant, whose capacity is now taxed to the utmost. The petitioners are Frank J. McCormick, of the Dayton (Ohio) Supply Company, who has claims for $4,379.53, with interest; John W. Johnson, of Dayton, who files a bill of $1,963.82, with interest, and Alexander Gebhart & Co., also of Dayton, who put in an account for $10,994, with part interest. The petition has been lodged in the District Court of the United States, South Division of Ohio, West Division. Receivers have been appointed in the persons of H. E. Talbott, president of the Stilwell-Bierce & Smith-Vaile Company, and William B. Earnshaw, an attorney of Dayton. The company is incorporated under the laws of the State of New Jersey, with a capital of $1,100,000, practically all of which has been issued. The assets of the company are put at $2,000,000, while the liabilities foot up a total of $1,250,000. The contracts in hand are understood to represent at least $500,000. It is confidently expected that matters will be adjusted satisfactorily within the next month or so. The company is taking orders right along and is figuring on some substantial contracts, especially for export to South America and England, in which countries it has been doing quite an extensive business for some years past.

Distribution of Shawinigan Power.

The Shawinigan Water & Power Co., which recently closed a contract with the Sorel Electric Co. for the delivery of power at Sorel, Quebec, has completed the transmission line to deliver the current from Shawinigan Falls. To meet the requirements, a transformer station was built at Joliette, Que., where the 50,000-volt current from the main line is stepped down to a voltage of 12,500. A line was then built from Joliette to the banks of the St. Lawrence River near Lanorale, following the right of way of the Canadian Pacific Railway. Across the St. Lawrence the current is carried by a submarine copper cable, heavily insulated and armored with lead and steel wire. On the south side of the river the line follows the public road until it reaches Sorel. Necessary steps have been taken to obviate danger from the river current or pressure of ice in the spring. Aluminum cable has been used throughout, this cable being manufactured by the Northern Aluminum Company, at Shawinigan Falls, the whole line being of much lighter construction than that employed in the main transmission line. The construction work was carried out by Messrs. Johnson & Saunders, contractors, of Buffalo, N. Y., the submarine cable having been supplied by the American Steel & Wire Company, of Worcester, Mass. A second line to Montreal, with a capacity of 10,000 hp, will be built, and this Sorel line is only the beginning of a series of short lines which will tap the main lines and carry power to points between Shawinigan Falls and Montreal.

Automobile Manufacturers.

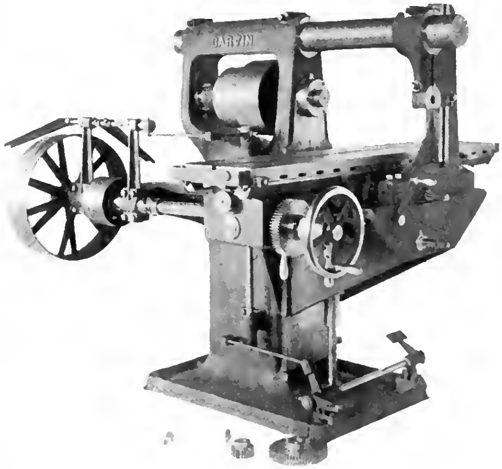
At a well-attended meeting of the executive Committee of the National Association of Automobile Manufacturers, which was held in New York last week, M. J. Budlong was re-elected president, while nearly all the other officers of the association were also retained. All the members of the executive committee were present except R. E. Olds. Windsor T. White was re-elected first vice-president; Charles Clifton, second vice-president, and R. E. Olds, third vice-president. W. R. Innis was elected treasurer in place of Percy Owen, who declined another term of office owing to increased business interests. The next meeting of the executive committee will be held on February 10, during the Chicago show. A special committee was empowered to enter into contracts for the automobile exhibits to be held at the St. Louis Exposition. It was reported that 40,150 square feet had been given to American manufacturers out of a total automobile space of 50,000 square feet. Mr. Budlong made an admirable report, with bright outlook, on the state of the industry.

Milling Machine for Brass Trolley Wire Hangers.

The accompanying illustration shows a milling machine made by the Garvin Machine Company for the rapid milling of brass trolley-wire hangers. It is fitted with power quick-return and automatic stop-motion. The machine is driven by a 5-in. belt, and the feed driven from the countershaft by a 24-in. pulley. The feed is direct through bevel and spur gears to a large steel screw or worm running in oil and meshing into a spiral rack or section of nut cut out of the solid on the under side of the table.

The hand-feed of the table is by hand wheel shown on front of saddle. This wheel is clutched so that it is not affected by the rapid rotation of the quick-return. Changes of feed are provided by change gears seen on front of saddle.

The feed stops at the end of the cut by automatic shifting of feed belt, and the work is taken out and quick-return thrown in by



MILLING MACHINE.

treadle action. The machine is controlled from either side. Special provision is made to check all over-run.

A long saddle is provided and supported by a very wide flat-top knee. The saddle is adjusted in and out by stop-nuts and bolted down on the knee by four bolts with swing handles, as shown. The vertical adjusting screw does not pass through the floor. The reverse is operated both by automatic trips and by hand or foot from either side of the machine. The cutter used is about 5 in. in diameter. In operation, the trolley hangers are held in a special fixture, and the chips flying up from the cutter are caught by an exhaust pipe and thrown into a barrel. Two flour barrels of chips per day gives a fair idea of the chip-removing capacity of the machine. A still further benefit of the exhaust, in addition to the removal of chips, is that it circulates air to the cutters and keeps them cool.

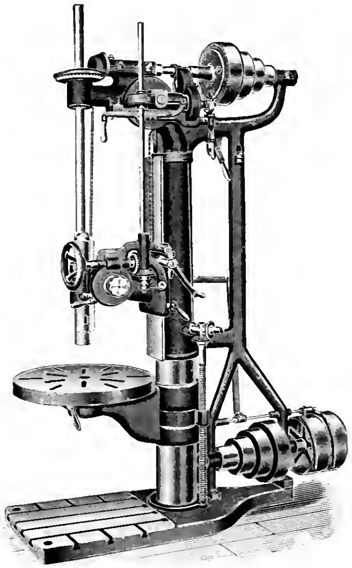
The length of the automatic feed is 30 in., and the in-and-out adjustment is 2 in The feed is 48 in. per minute, the speed of the spindle being 550 r.p.m. The weight is 4,900 pounds and the floor space 5 ft. 6 in. x 9 ft. 6 in. The table is 62 x 13 in.

Positive Self-Feed Upright Drill.

A positive self-feed drill embodying many notable improvements, has been brought out by W. F. & John Barnes Co., Rockford, Ill. The illustration herewith shows plainly the construction. On the larger tools there are eight changes of feed, and on the smaller sizes four changes of feed. All these different feeds vary from one adapted for reamer work, or one for drilling in steel, to one of suitable coarseness for boring in cast iron.

A feed index plate is provided on each machine so that the operator may tell at a glance the feed being used. It is claimed that this positive feed will increase from 15 to 25 per cent. the output of a drill press; firstly, because the action is absolutely positive and does away with any slipping belts; secondly, the feed can be changed by a simple movement of the lever while the drill is running.

There is another point that the drill covers, in that it offers a variety of feeds adapted to the high-speed cutting steels that are

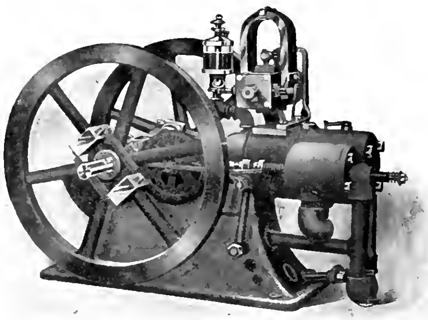


UPRIGHT LATHE.

on the market to-day. With the positive feed the operator is in position to use either slow-speed steel or high-speed steel. The question of high-speed steel is something to be considered, and machines must be adapted for their use.

Small Gas Engines.

The gas engine illustrated below is made up from castings furnished by the Carlisle & Finch Co., Cincinnati, Ohio. This engine will develop ½ hp at a speed of 375 r.p.m. The castings are furnished in the rough; the cylinder, however, is bored out and faced off, but no other work is done on any of the castings. A complete



SMALL GAS ENGINE.

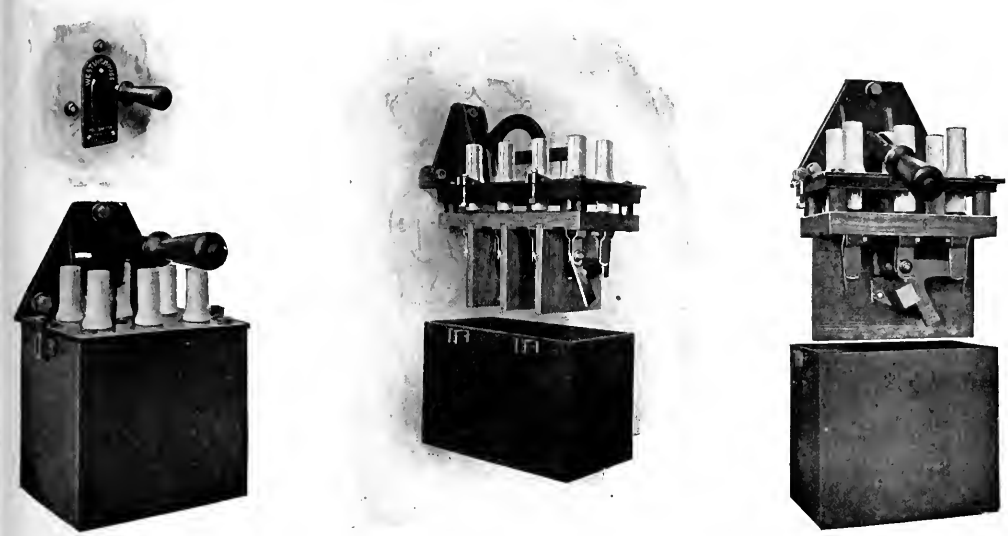
book of instructions telling how to perform every operation is furnished with the castings, and the manufacturer also furnishes all bolts, nuts, springs, screws, forgings, etc., so that nothing has to be purchased elsewhere in making up the finished engine.

The Carlisle & Finch Co. also makes a specialty of furnishing castings and dynamos, motors, electric miniature railways and a complete line of goods for amateur electricians.

New Westinghouse Oil Switch.

The value of oil as an insulating and arc suppressing medium in high-tension current-interrupting devices used where space is a factor is universally known, and the equipment of the modern central station usually contains evidence of the general approval of apparatus of this kind. Its reliability, small amount of attention required to keep it in order, compactness and consequent ease of installation give such apparatus an especial adaptability for use in many locations.

A new addition to the line of oil-immersed circuit-breaking apparatus manufactured by the Westinghouse Electric & Manufacturing Company, and designated as "Type D," is shown in the accompanying illustration. In a number of particulars it has no counterpart in other oil switches now on the market. It is made with two, three and four poles, single and double-throw, in all capacities up to and including 1,000 amp. and voltages up to 3,300. The ultimate breaking capacity is given at 600 kw for single-phase, 1,200 kw for two-phase, and 1,000 kw for three-phase.



Figs. 1, 2, 3 and 4.—Oil Switch.

Styles are made for wall mounting and for switchboard use, as illustrated. When used upon a switchboard, the switch is mounted upon the back of the panel, the handle projecting through to the front. The visible portions are finished in copper and dull black, in pleasing harmony, and forming an effective contrast with the marble panel. As regularly made, the switch is designed for use upon marble two inches thick, but by substituting shorter bolts it can be as easily mounted upon panels of lesser thickness. The handle of the double-throw switch is locked when the switch is open. Pressing upon a button in the end of the handle releases it and the circuit is closed by a pressure either up or down, the directions in which it is the easiest to apply force, and which cause the least strain upon the panel.

This type of oil switch is very generally used with motors, mounted upon an adjacent wall or post. It is one of the smallest oil switches made, and its size, compact form, ease of making connections, thorough insulation of connections when made, and facility with which the interior can be inspected give it a superior adaptability for use under the various conditions applying to such installations.

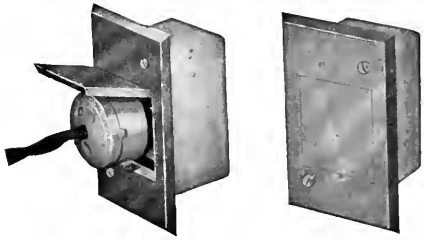
The mechanism is notable for its simplicity and efficiency. The design provides for the fewest possible number of links in the operating device. The switch is of the knife blade or jaw type, and gives a maximum amount of contact with a low temperature rise, which will not exceed 20° with a normal current. The final arc is taken upon an arcing tip, which is renewable. By this provision, no damage is done to the main contacts, and the life of the switch is prolonged indefinitely.

Surface and leakage distances have been carefully studied out and ample provision made. Contacts are thoroughly insulated. They are mounted on a wooden base suspended from the iron supporting frame, and at all times immersed in the oil. Each pole is isolated by a barrier of wood, which has been subjected to a treatment to give it high insulating qualities, and any possibility of communication of an arc between poles is thus avoided. The leads are brought out at the top, connections to the circuit being made inside the switch, and a porcelain insulator slipped over the joint. By this means all conductors are kept outside the oil tank.

The tank is of sheet metal, having a suitable insulating lining and is attached to the case by bolts. The lugs through which the bolts pass are slotted, and when the nuts are loosened the bolts can be lifted out sidewise, thus facilitating removal of the tank. The form of the tank, and the interposition of the wooden barriers between the poles, appreciably reduce the amount of oil required, and the danger of ignition during a fire. "Kilarc" oil is used, which is especially compounded for insulating purposes, and has a fire test of over 400° F. Its freedom from acidity and volatile matter give it high insulating properties, and make the evaporation low, while its viscosity renders it effective for extinguishing the arc.

Flush Wall Receptacle.

A flush pocket wall receptacle manufactured by the General Electric Company, of Schenectady, N. Y., and one offering many advantages, is shown in the accompanying illustration. It presents an attractive



FLUSH POCKET RECEPTACLES, OPEN AND CLOSED.

appearance, whether in use or not, and does not require a special attaching plug which could not be used in other sockets or receptacles in the same installation. It is a very handy device in connection with fan motors, desk lights, etc. The face-plate is of heavy brass having a polished nickel finish, other finishes being furnished when called for.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—The market was strong and prices showed an advancing tendency. Standard stocks, like Pennsylvania, Union Pacific and issues of that character, together with the better class of industrials, were strong and active. The United States Steel stocks advanced under the influence of better reports regarding steel trade conditions, the preferred being particularly well bought, rising to 59; while the new 5 per cent. bonds went up to 75½. While sharing in the improvement, nothing of particular importance developed in the traction group apart from the decided strength of Interborough Rapid Transit, or Subway stock, in the curb market. Amalgamated Copper was quieter than usual, improving, however, on the announcement made on Thursday that the regular quarterly dividend of ½ per cent. had been declared. There was considerable selling activity in Brooklyn Rapid Transit, the total number of shares changing hands being 110,260. This stock closed at 50¼, thus gaining 1¾ points net. Metropolitan Street Railway made a net gain of 2 points, closing at 123; and Manhattan Elevated 2¾ points, the closing price being 145. The electrics showed strength under the influence of the improvement in the general market and General Electric made a net gain of 8¾ points, closing at 177¾. Westinghouse common was active, 7,900 shares being sold at prices ranging from 173⅞ to 167, the lowest, the closing figure being 172, which is a net gain of 4½ points. Westinghouse first preferred closed at the highest figure of the week—194—and gained 2⅞ points. Western Union remained about steady, closing at 88, and American Telegraph & Telephone closed at the highest figure of the week—128⅛—being a net gain of 2⅛ points. Following are the closing quotations of January 26:

KEYSTONE TELEPHONE.—President John M. Mack, of the Keystone Telephone Company of New Jersey, makes the following annual report for the fiscal year ended December 31, 1903:

Assets:	
50,000 shares, being all of the common stock of Keystone Tel. Co. of Phila.	$4,433,712
2,500 first mortgage of the Keystone Tel. Co. of Phila.	2,500,000
Current assets	439,982
Taxes (prepaid)	2,408
Total	$7,376,102
Liabilities:	
100,000 shs. pfd. stk. (6% cumulative) @ $50 each (less unsubscribed)	$1,936,800
100,000 shs. com. @ $50 each, fully paid	5,000,000
Current liabilities	312,636
Accrued liabilities (interest)	8,150
Int. rec. in excess of int. pay. from Jan. 16, 1903, to Dec. 31, 1903	118,516
Total	$7,376,102

NEW YORK CONSOLIDATED GAS.—The surplus earnings of Consolidated Gas Company for the fiscal year ending December 31, 1903, after the payment of dividends, amounted to more than $2,500,000, as compared with $2,100,000 in 1902 and $1,500,000 in 1901. In the absence of President Gawtry, who was prevented from attending the annual meeting by illness, Vice-President Addicks made a statement regarding the operations during the past year. He pointed out that the company had difficulty in obtaining fuel early in the year, the scarcity caused by the anthracite strike in 1902 extending over to the early part of 1903. The output of gas and electricity, the surplus earnings, together with other operating statistics, compare with the preceding year as follows:

	1903.	1902.
Surplus earnings	$2,500,000	$2,100,000
Sales of gas (cubic feet)	20,227,832,000	18,358,478,000
Average candle power	23.97	24.27
Miles of mains	1,762	1,753
Services	188,973	198,637
Meters	580,287	556,063
Stoves, ranges sold and rented	36,208	42,632
Electric current sold, kilowatts	107,256,189	88,500,040
Electric customers gained	6,325	4,700
Expenditures in construction	$7,035,796	$5,022,987
Charged off for repairs	1,799,015	1,335,428
Charged off for depreciation	1,023,934	744,400
Charged off for taxes	1,727,372	1,755,685
Employes benefit societies	21,753	18,916
Coal and coke used, tons	1,029,433	947,053

CROCKER-WHEELER COMPANY.—The annual report of the Crocker-Wheeler Company, Ampere, N. J., for the year ending December 31, 1903, shows a decided gain over the preceding year. The results of the year's operation must be highly gratifying to the officers and stockholders, and it is certainly an encouraging showing for all interested in electrical development. While this company is widely known as one of the leading manufacturers of large generators and power motors, we think it will come as a surprise to those who have not followed closely the course of electrical development, to learn that last year its gross business amounted to more than two millions of dollars; in other words, it turned its capital over twice in twelve months. The gross profit for the year's operations was $519,781, and after paying fixed charges, dividends, reserves, etc., a balance was carried to surplus of $167,994, making the total surplus to date $408,868. At the time of the report orders amounting to more than a half million dollars were passing through the works, which, though recently enlarged, are now crowded to their capacity. President Wheeler, under whose able management this institution has grown up, is to be congratulated on this evidence of stability and prosperity.

ELECTRIC STORAGE BATTERY.—A director of the Electric Storage Battery Company is quoted as saying: "The Storage Battery Company made net earnings of more than 10 per cent. on its stock during 1903. The surplus will be substantially greater than that of the previous year, which was about $300,000. The company has all the work it can do. There is nothing to prevent our continuing to pay dividends as in the past. The Edison battery has not yet proved itself a factor in the market. The Electric Storage Battery Company has practically all the business in the United States. We are also getting our English company into good shape."

THE FALL RIVER AUTOMATIC TELEPHONE COMPANY has paid its fourth quarterly dividend at the rate of 5 per cent. per annum. It now has 1,160 stations, an increase of about 100 for the quarter. Although its toll rate to the New Bedford Automatic exchange is 10 cents, and the New England Telephone & Telegraph Company has reduced its rate from 15 cents to 5 cents between these points, the earnings of the Automatic Company's toll lines show a steady increase.

ILLINOIS TELEPHONE COMPANY SELLS OUT.—The Illinois Telephone and Telegraph Company, according to advices from Chicago, on January 18 filed a bill of sale of all its property, including tunnels, tracks, automatic switchboard appliances, telephone system, etc., to the Illinois Tunnel Company, which was recently chartered with a capital stock of $3,000,000.

AMERICAN TELEPHONE & TELEGRAPH.—The recent advance in American Telegraph & Cable stock to 86¼ on sales of 1,050 shares drew from President Clowry, of the Western Union, the following remark: "It is a 5 per cent. guaranteed stock, and I have wondered why it has not been quoted higher. The Western Union owns most of the stock."

STOREY RECEIVER DIVIDEND.—George R. Beach, of Jersey City, receiver for the Storey Motor and Electric Company of Harrison, N. J., has announced that he is ready to pay to his creditors a first dividend of 25 per cent. The proved claims against the company amount to $33,500.

NORTHERN OHIO TRACTION shows $882,276 gross for the year, net $399,701 and charges $268,132, leaving a surplus of $131,569.

CENTRAL UNION TELEPHONE.—The Central Union Telephone Company reports for the year ended December 31, 1903, an increase in surplus of $140,000. H. F. Hill has been added to the board. The following comment from Boston as to the outlook in the Central States will be of interest: "The reorganized Bell Telephone properties should do well upon their present basis of capitalization, which is far below the cost of duplication with all the water squeezed out. The Western Telephone Company properties allowing $8 for the common stock, $80 for the preferred and $100 for the bonds, sells at $24,080,000, or not much over $120 per subscriber, against $240 per subscriber for many of the Bell companies that have not been scaled down. The Michigan Telephone property, valued at $13,000,000 in the hands of its bondholders at about $5,500,000, $110 per subscriber, with constantly increasing earnings, will take care of itself in good shape. The Central Union Company capital was cut in two—that is, reduced from $6,000,000 to $3,000,000, increased again to $6,000,000 the Bell and a few stockholders putting in $3,000,000. It has already spent this new money and is a small borrower, and it has out $6,000,000 bonds. The company has not done as well as was expected on account of being in the hot-bed of competition, the Middle West." The Central Union Telephone Company reports as follows for the year ended December 31:

	1903.	1902.	1901.	1900.
Gross	$3,181,120	$3,003,717	$2,584,789	$2,309,471
Expenses	2,426,172	2,341,989	1,973,501	1,674,395
Net	$754,948	$661,728	$611,288	$635,076
Charges	438,796	481,383	386,762	317,567
Surplus	$316,152	$180,345	$224,526	$317,509

MARCONI WIRELESS REVENUES.—It is stated that at a recent meeting of the directors of the Marconi Wireless Telegraph Company of America, there was a lively discussion of questions involving the future policy of the company in its dealings with the English company. The traffic of the Marconi system has increased so rapidly, especially in the matter of dispatches originating abroad for delivery in the United States, that the existing conditions with respect to a distribution of the revenues are considered by the American interests to be inequitable. The English company insists that the basis of the original provision was upon a world-wide foundation, being of universal application to all Marconi companies wherever organized, and that though it appears inequitable at this time, owing to the fact that the foreign business has not yet developed equally with the American business, it will, in the end, prove to be as profitable an arrangement to the American company as to any other. The American company contends that the proportion is not as great as the superior progressiveness of the American people entitles it to receive, and it believes that in the end the arguments of the American interests will prevail and that a new arrangement will be perfected whereby a larger proportion of the earnings of the Marconi system will find its way into its coffers. This question has been under discussion for some time between the officers of the respective companies concerned, but was only recently brought to the attention of the directors.

TORONTO TROLLEYS ANNUAL REPORT.—The Toronto Street Railway reports as follows for the year ended December 31, 1903:

	1903.	1902.		Changes.
Gross	$2,172,087	$1,834,908	Inc.	$337,179
Expenses	1,200,823	1,015,361	Inc.	185,462
Net	$971,264	$819,547	Inc.	$151,717
Passengers carried	53,055,322	44,437,678	Inc.	8,613,644
Transfers	18,654,344	15,979,220	Inc.	2,680,124

After paying all charges and transferring $50,000 to the contingent account there remained a surplus of $180,638. Mr. J. C. Grace was added to the board of directors to take the place of Mr. James Ross, of Montreal, who resigned.

LIGHTING DEAL IN BALTIMORE.—A special telegram of January 18 from Baltimore, Md., says: "New York lighting interests, headed by Anthony N. Brady, were to-day given representation in the directory of the United Electric Light & Power Company. This is the company back of the scheme for utilizing the rapids of the Susquehanna River in the vicinity of Conewago for electric development. The four new members of the board, representing the New York interests, are Anthony N. Brady, his son, Nicholas F. Brady, Samuel A. Beardsley and Thomas E. Murray, all of New York. Mr. Murray is the general manager of the New York Lighting Companies controlled by the Brady syndicate. A. N. Brady is also made a member of the executive committee."

DIVIDENDS.—The American District Telegraph Company, of New Jersey, will pay a quarterly dividend of 1 per cent. on its capital stock January 22. This is a reduction of ¼ of 1 per cent. from the previous payment. The Western Telegraph & Telephone Company has declared a regular semi-annual dividend of $2 per share on the preferred stock, payable February 1, to stockholders of record January 22. National Carbon directors have declared the regular quarterly dividend of 1¾ per cent. on the preferred stock, payable February 15. American Graphophone directors have declared the regular quarterly dividend of 1¾ per cent. on the preferred stock, payable February 15.

Commercial Intelligence.

THE WEEK IN TRADE.—The conditions everywhere are extremely favorable, and optimism prevails in regard to the outlook for spring business. There is an enlarging volume of business at Southern and Southwestern markets and an awakening of interest at some Northwestern centres and growth at Central Western and Eastern markets. At the South there is confidence, based on the high price for cotton. Preparations for an enormous acreage are going forward. Chicago reports spring trade not yet opened, but signs of life are apparent. The iron trade is irregular as a whole, and variously regarded, according as the point of view shifts from crude to finished products, or the observer is located East or West. The lighter finished products of iron and steel are, however, in pretty good shape, and demand is higher. There is a better feeling in hardware, and in heavy structural steel and rails more talk of business is heard, although it is said that the railroads are rather backward in placing orders. Lumber and building materials are quiet and there is a promising outlook for spring business. In the metals, copper and tin are lower, while lead is higher. Copper was very quiet, and the demand was light. Exports continue on a large scale, at the present time amounting to 15,500 tons for the month, and it is estimated that the total of the entire month will foot up about 20,000 tons. Closing quotations were 12¾c. for Lake, 12⅝c. for electrolytic and 12¼c. for casting stock. It is said that a large German house made an offer to the United Metals Selling Company for 50,000,000 lbs., which was readily accepted, and shipments on this order are being made with equal promptness. *Bradstreet's* reports 266 business failures during the week ended January 21, as against 315 the week previous and 253 the corresponding week last year. About 87 per cent. of the failures had capital of $5,000 or less, and 9 per cent. at from $9,000 to $20,000 capital.

ELECTRICAL PARTS IMPORTED.—United States General Appraiser Israel F. Fischer has handed down a decision on the classification of so-called stamped steel shapes, which are used in the construction of electrical machines. Some of them are plain and others coated on one side with a preparation of flour paste and talcum, which serves to insulate them. Both were assessed at 45 per cent. as manufactures of metal, and the importers, Thomas Meadows & Co., of New York, claimed that they should be classified as "steel not specially provided for" at 1 3/10 cent a pound. This claim was allowed on the uncoated plates, but on the others Mr. Fischer ruled that the coating had so changed their character as to make the claim untenable.

FIVE THOUSAND H.P. EQUIPMENT FOR SYDNEY.—Contracts have at last been awarded for some of the further equipment to be installed in the power station of the Sydney City and Suburban Tramways. This system is being considerably extended by the New South Wales Government. About 70 miles are already in operation. The existing equipment of the power house includes General Electric generators, Allis engines and Babcock & Wilcox boilers. The boilers for the additional installation of 5,000 hp. will also be of Babcock & Wilcox build. The heaters have been ordered from the Joubert Manufacturing Company. The electrical machinery is expected to be contracted for very shortly.

FIRE IN E. W. BLISS COMPANY'S FACTORY.—On Friday afternoon, January 22, fire at the main works of the E. W. Bliss Company, in Brooklyn, destroyed property valued at $250,000. The fire was confined to the new section of the plant, which was six stories in height. The officers of the Bliss Company state that the loss is fully covered by insurance. There were 1,500 employees in the factory at the time, but they all escaped unhurt. A sad feature of the fire was the killing of Lieut. Gibson, of one of the fire companies, who fell from a ladder, 60 feet, and was impaled on a hook on the fire truck. The hook penetrated Gibson's heart, causing death in a few minutes.

MEXICAN HYDRAULIC PROJECT.—The construction of a hydraulic plant is contemplated on the River Grande de Santiago, in the municipality of Hostotipaquillo, Canton of Ahualulco, State of Jalisco, Mexico. The necessary concession has been secured from the Mexican Government by F. Brennan, of Mexico City. The franchise permits of the utilization of 15,000 liters of water per second.

SHIPMENTS OF FRANCKE ENGINES.—The Maxfield-Francke Company, of 120 Liberty Street, New York, reports the following shipments of the Francke Four-Ported engine: Under-Feed Stoker Company of America, Chicago, Ill., first order 7 x 6 engine, direct-connected to steel plate forced-draft blower. Struthers-Wells Company, Warren, Pa., 7 x 6 engine, for operating mechanical stoker. James Beggs & Co., New York, 4 x 3½ engine for operating mechanical stoker. Mershon Patent Shaking Grate Works, Philadelphia, Pa., 5 x 4 engine for operating disc ventilating fan. M. A. Hicks, Springfield, Vt., 4 x 3½ engine for driving dynamo. Under-Feed Stoker Company of America, Chicago, Ill., second order 5 x 4 engine, direct-connected to steel plate forced-draft blower. Iowa Heat, Light & Power Company, Des Moines, Iowa, 7 x 6 engine direct-connected to centrifugal pump. Linn Woolen Mills, Hartland, Me., 5 x 4 engine, direct-connected to steel plate blower. Lever Bros.' Soap Works, Cambridge, Mass., 7 x 6 engine for operating mechanical stoker. Robert Dobson Co., Pittsfield, Me., 7 x 6 engine, direct-connected to steel plate blower. McClave-Brooks Co., Scranton, Pa., 4 x 3½ engine for operating mechanical stoker. George Bowen, South Charleston, N. H., 4 x 3½ engine for driving dynamo. McMurtrie-Guiler Co., New York, 5 x 4 engine, direct-connected to centrifugal pump for export to Porto Rico. Iowa Heat, Light & Power Company, Des Moines, Iowa, second order 5 x 4 engine, direct-connected to centrifugal pump. Northern Engineering Company, New York, 4 x 3½ engine for driving dynamo. J. Heidingsfeld, New Brunswick, N. J., 5 x 4 engine for running printing plant. In addition to the above list, they have several different makes of generators at the works, for which engines are almost ready for direct-connecting, and which will be shipped to various points in the United States at an early date. Some of these engines are operating as low as 100 r.p.m., while others operate at all intermediate speeds up to as high as 800 r.p.m.

BARB WIRE TELEPHONE DEAL.—It is stated that a merger of two telephone lines owned and operated by farmers in Washington State has been made, and that there are prospects that all rural lines centering in or around Pullman in Eastern Washington will be consolidated. There are fully three hundred miles of rural telephone lines constructed and operated on the coöperative plan by farmers in the vicinity of Pullman. The central station is maintained there, with Lewis L. Wright as manager. Wright owns the central station and several rural lines, and all lines are connected with his station, where an operator connects each line with any other line over which it is desired to converse. For this service, "central" charges 35 cents per telephone per month. The merger price will be 40 cents. Fully two hundred families living on farms have telephone connections in this way, and the system has proven a great luxury to the wives of the farmers, as well as a convenience to the farmers themselves. These telephone systems are the outgrowth of the barbed-wire telephone system built by J. S. and J. M. Klemgard and J. L. Metsker, four years ago.

THE HOLTON POWER COMPANY, Holton, Cal., is developing water power on the large Imperial irrigating canal, and will sell electricity for light, heat and power. An electric railway to Imperial, 12 miles distant, is also being built. About 650 hp. will be developed at first, and the station will have an ultimate capacity of 1,500 to 2,000 hp. When it is considered that this canal and the power development are about 200 ft. below sea level, considerable interest attaches to the project. Another interesting feature is that quite a market is anticipated for electric heat for cooking and household purposes. Coal sells as high as $18 a ton at Holton. Wood is correspondingly high, and it is said that electricity can be sold for heating and cooking at a cost not to exceed 1¼ times the cost of gasoline, with, of course, greater convenience and cleanliness. Samuel Starrow, of Los Angeles, is consulting as well as constructing engineer for the Holton Power Company.

BELL TELEPHONE OUTPUT.—The American Telephone & Telegraph Company instrument statement for the month ended December 20 and since December 20 compares with the month ended December 20 and the period from December 20 in previous years as follows:

	1903.	1902.	1901.
Gross output	88,947	92,732	63,196
Returned	39,678	34,688	23,593
Net output	49,269	58,044	39,603
Since Dec. 20:			
Gross output	1,109,888	960,055	683,955
Returned	480,691	386,861	311,645
Net output	629,197	573,194	372,311
Total outstanding	3,779,517	2,526,010	1,952,816

MORE EQUIPMENT FOR MANILA.—The Manila Electric Railroad & Light Company has just placed some further contracts through J. G. White & Co., 40 Exchange Place, New York, for equipment to be installed in the power house, to be erected in Manila, Philippine Islands, for electric traction and lighting. The Alberger Condenser Company, 95 Liberty Street, New York, has taken the contract for the condensers, which will consist of a high vacuum surface condensing equipment to take care of each of the three 700-kw Westinghouse turbine units. The condensers will operate on the counter current dry system. The United States Steel Products Export Company, which concern was recently formed to handle the foreign trade of the United States Steel Corporation, has been awarded the contract for the steel.

THE BROWNLOW BILL.—There is a strong sentiment apparently throughout the country in favor of the new Brownlow Bill now pending in Congress, which appropriates $24,000,000 as national aid for the building of wagon roads. This money is to be distributed according to the population of each of the States, except that the States having less than 700,000 people are to receive a minimum amount of $250,000. Each State, county or town receiving national aid must add a like amount. This bill will result in the spending of $48,000,000 for the building of wagon roads and will build from 100 to 500 miles of good road in every State of the Union. Such roads would be a universal boon.

ALUMINUM CIRCUITS.—It is stated that within a year the Boston Edison Electric Illuminating Co. has purchased 298,245 pounds of aluminum wire, which represent a total of 246 miles. The Massachusetts Electric Company has purchased about 500,000 pounds as a substitute for copper. The Boston & Maine Railroad, the Tucker, Anthony & Company properties, Hartford Electric Light and the New Milford (Conn.) Power Company have all placed large orders for aluminum wire. The Lewiston & Auburn Electric Light Company also has equipped its lines with aluminum.

IMPORTED ELECTRICAL SCARF PINS.—United States General Appraiser Thaddeus S. Sharretts has overruled a protest by the American Electrical Novelty Company of New York against the assessment of 60 per cent. duty on jewelry on parts of electrical scarf pins. The articles consisted of eight imitation diamonds set in base metal. The importers claimed that they were dutiable at 45 per cent. as manufactures of metal, glass, or paste. Gen. Sharretts overruled these claims on the ground that they were components of articles generally known as jewelry.

NORTHERN CALIFORNIA POWER.—In 1901 the Northern California Power Company contracted for three Pelton water wheel units, each 1,600-hp capacity, operating under a head of 1,150 ft., for its electric transmission plant on Battle Creek, a few miles from Anderson, Cal. In 1902 the Pelton Company received an additional order for two 3,000-hp units, operating under the same head. The Northern California Power Company furnishes electricity for power and lights for all the important mining and farming towns within a distance of 80 miles of its plant.

WILLARD STORAGE BATTERIES.—The Willard Storage Battery Company, Cleveland, Ohio, the well-known manufacturer of storage batteries, has moved into larger quarters at Twenty-seventh and Clair Streets. It will install 200 hp of boilers and engines and two 75-kw generators for lighting and power. It will buy considerable new machine tool equipment and will install a complete wood-working equipment for manufacturing its own battery cases. Mr. T. A. Willard is general manager of the concern.

CALIFORNIA POWER TRANSMISSION.—A very important installation of Pelton water wheels was recently completed near Placerville, Cal., for the American River Electric Company, consisting of two double Pelton units of a capacity of 2,500 hp, operating under a head of 575 ft. This concern is situated on the American River, within a few miles of the state capital, Sacramento, and will generate electricity for near-by towns.

POWER TRANSMISSION IN CALIFORNIA.—Poles and wire have been bought for the Temescal Water Company's 30-mile transmission line in California from its electric power plant at Ethanac to the wells in the Temescal basin. At a regular meeting of the company's board of directors, President F. F. Chase was authorized to select a superintendent to succeed A. C. Miller, resigned.

EQUIPMENT FOR RUSSIA.—M. Gradstone & Company, 2 and 4 Stone Street, New York, who conduct an extensive export trade with Russia exclusively, have received some large inquiries for various electric traction and lighting equipment.

OMAHA POWER HOUSE.—General Manager Smith, of the Omaha-Council Bluffs Street Railway Company, has announced that the new power house capable of generating 6,000 hp., will be completed at a cost of $500,000.

BAKER PLATINUM.—Since January 1, the well-known platinum house of Baker & Company has become Baker & Company, Incorporated, with C. O. Baker as president, and C. W. Baker as vice-president and treasurer.

BALL ENGINE ORDERS.—The South Dakota Agricultural College, of Brookings, S. D., has recently purchased an automatic engine from the Ball Engine Company, Erie, Pa.

General News.

THE TELEPHONE.

DENVER, COL.—The Washington County Telephone Company, with a capital stock of $5000, has been incorporated by H. W. Twombly, C. D. Pickett and M. H. Spere, Akron, Col.

CENTER POINT, IND.—The Center Point Telephone Company has been incorporated with a capital stock of $5000. The directors are H. F. Weber, L. Lansit and others.

INDIANAPOLIS, IND.—The New Long-Distance Telephone Company has paid its regular quarterly dividend of 1 per cent. The company is planning numerous extensions to be made during the summer.

DUNKIRK, IND.—Ed. V. Fitzpatrick, a resident of Portland, has secured a controlling interest in the Citizens Telephone Company, of this city, and has succeeded in electing a board of directors of his choice. The action has displeased the stockholders.

INDIANAPOLIS, IND.—The West Fork & Sulphur Home Telephone Company has filed articles of incorporation with the Secretary of State. The company has a capital of $4000. The principal exchange will be in West Fork. George F. Dewett is president.

SILVER LAKE, IND.—The stockholders of the People's Mutual Telephone Company have elected H. L. Oldfather, Arthur Smith and Amar N. Igo, directors. The company now has 525 telephones and 90 miles of toll lines. Last year 184 telephones were installed.

CRAIGSVILLE, IND.—The people of Craigsville are clamoring for a better telephone service from that which is now furnished them by the Bell Company, which they say is not sufficient to satisfy their needs. The Bell is not an all night service. A movement is on foot to get the United Telephone Company to run a line to Craigsville.

MUNCIE, IND.—The Central Union Telephone Company has decided to expend $50,000 in improving and extending its service in Muncie and Delaware Counties. This is made necessary, it is said, by the competition of the Delaware & Madison Counties' Telephone Company which recently expended a large sum in completing a new plant here and which is giving excellent service over a wide territory.

INDIANAPOLIS, IND.—The ten-party lines of the Central Union Telephone Company in this city, are to be replaced as rapidly as possible by a four-party line system. The ten-party line subscribers paid $1 a month. The four-party line service will cost $1.25. More than $30,000 will be spent by the company during January in new switchboards and dynamos for the central plant. A new switchboard will also be placed in the exchange at Irvington.

GENESEE, IDA.—At a meeting of citizens held here recently, it was decided to organize and operate a local and rural telephone system.

ESTHERVILLE, IA.—The citizens of this place have asked the council for a telephone franchise.

HUDSON, IA.—The Hudson Mutual Telephone Company is the name of a new company just organized here with H. B. Eighmey as president.

HAMILTON, MONT.—The Bitter Root Telephone Company will extend its system as far as Darby. The line will also connect with the logging camps of the Anaconda Copper Mining Company.

ST. JOSEPH, MO.—The Board of Public Works proposes to have all telephone and telegraph wires within the business district of this city placed in underground conduits. The cost of the work will be about $500,000. The matter is in the hands of City Electrician Floyd and an ordinance will soon be drawn up.

SEDALIA, MO.—The strike of the Missouri & Kansas Telephone Company linemen has been settled. A nine-hour day instead of ten hours, and an increase in pay from $2.25 to $2.40 a day were granted. The men asked for $2.50 per day; one and one-half pay for overtime and double pay for Sundays and legal holidays.

RENO, NEV.—A representative of the Automatic Telephone Company has been here looking into the feasibility of establishing a system here and at adjacent points.

LANCASTER, N. Y.—The Bell Telephone Company has applied to the village authorities for a franchise.

RIVERHEAD, L. I., N. Y.—Th Baiting Hollow & Roanoke Telephone Company of this town has increased its capital stock from $5000 to $20,000.

ROME, N. Y.—At the annual meeting of the Rome Home Telephone Company Mr. Fred M. Shelley was re-elected president; John S. Wardwell, vice-president, and D. Odell, secretary, treasurer and manager. The business of the company has increased rapidly and now over 1000 telephones are in service. When the business was first started provision was made for an exchange for 500 telephones.

SALISBURY, N. C.—The Southern Bell Telephone Company has bought the local exchanges at Salisbury and at Spencer, N. C., and it is said that improvements will be made. The transfer of the franchises seems to meet with public favor.

RANDLEMAN, N. C.—The Randleman Telephone Company has been chartered by the Secretary of State with $5000 authorized capital stock and $3000 paid in. S. Bryant, T. E. Marshall, Jr., and H. O. Barber, all of Randleman, are the incorporators.

PAINESVILLE, OHIO.—The Bell Telephone Company is planning to spend $15,000 in improving its plant here.

FINDLAY, OHIO.—The Central Union Telephone Company is preparing to make important improvements at its Findlay exchange.

GARRETTSVILLE, OHIO.—The Portage County Telephone Company has erected a new line from Garrettsville to Parkman and is projecting other extensions.

TOLEDO, OHIO.—The Central Union Telephone Company states that it has added 1200 new subscribers to its service since the issue of its last telephone list.

WEST UNION, OHIO.—The Central Union Telephone Company has just completed a line from North Liberty to West Union and will build a new line to Eckmansville.

BRUNSWICK, OHIO.—The Brunswick Independent Telephone Company has been incorporated with a capital stock of $5000. The directors are M. J. Hawkins, A. D. Alyard and others.

BUCYRUS, OHIO.—The Bucyrus Telephone Company has recently erected a number of farmers' lines and the service is proving so popular that other farmers' lines are to be built throughout the entire district.

IRONTON, OHIO.—The Ohio Valley Telephone Company, capital stock $2000, has been organized by H. P. Gerlach and others of Ironton. The company will build an exchange at Proctorville, Ohio.

BEALLSVILLE, OHIO.—The White Telephone Company is preparing to extend its lines to Woodsfield and Cameron. Connection with the long-distance system of the United States Telephone Company will be made at Bellaire.

AKRON, OHIO.—James B. Douglas, manager of the Alliance exchange of the Central Union Telephone Company has been made manager of the Akron exchange of the company. Extensive improvements are to be made at Akron.

KIRTLAND, OHIO.—The Kirtland Telephone Company has been organized by A. G. Tyron, Henry Hooper, W. R. Creary, W. A. Criswell and I. A. Harris. Capital $2,500. The company will build a local system in Kirtland and vicinity.

AKRON, OHIO.—The Summit Rural Telephone Company has organized with W. F. Laubach, president and general manager; E. A. Hawkins, secretary, and H. C. Spicer, treasurer. The company recently built lines to Ghent, Wordon, Montrose and Hammond.

LORAIN, OHIO.—The mayor has vetoed a franchise application made by the Bell Telephone Company and the latter will appeal to the Probate Court. The Black River Telephone Company, the independent company, is endeavoring to block the entrance of the Bell Company.

MANSFIELD, OHIO.—The Mansfield Telephone Company has elected the following-named officers: S. N. Ford, president; J. L. Baxter, vice-president; M. D. Ward, secretary-treasurer. The company enjoyed much prosperity last year and is planning to make improvements this spring.

WADSWORTH, OHIO.—The Wadsworth General Electric Company contemplates building a six-mile party line. It has 200 subscribers, 40 of which were added last year. The company uses North Electric apparatus and charges $10 a year for residence service and $15 for business.

MARTINS FERRY, OHIO.—The Bell Telephone Company has perfected an arrangement with farmers in this vicinity whereby if they secure a certain number of subscribers and erect their own pole lines the company will supply telephone service at a low price. Connection is made with the Martins Ferry exchange.

BRILLIANT, OHIO.—The Ohio Valley Telephone Company, of Brilliant, has organized with Robert Carpenter, president, and J. G. Gilchrist, secretary. The company will build lines along the river front in Jefferson County and will connect up all the independent companies in that vicinity. A large number of lines will be built at once.

SHEAKLEYVILLE, PA.—The Sheakleyville Telephone Company has been organized with H. Orr as president.

YORK, PA.—The stockholders of the York Telephone Company held their annual meeting recently and elected directors, who elected officers as follows: President, D. F. Lafean; vice-president, John McCoy; secretary, H. H. Weber; treasurer, C. C. Frick. The board of directors recently declared a dividend of 2 per cent on the stock.

CUMBERLAND GAP, TENN.—The Cumberland Gap Telephone Company has been incorporated with a capital stock of $10,000. The directors are G. W. Fortune, J. H. Quillen and others.

EL PASO, TEX.—The Southwestern Telegraph & Telephone Company has purchased a site here for its proposed telephone exchange building and the contract will soon be let for its construction.

SALT LAKE CITY, UTAH.—The Utah Independent Telephone Company has been granted a franchise by the county commissioners to extend its lines through the county.

PULLMAN, WASH.—A consolidation of all the rural telephone lines owned by farmers in the vicinity of this city has been effected. These lines are about 300 miles in extent.

ADAMS, WIS.—The Adams Telephone Company has been incorporated with a capital of $2000. The directors are Christ Reuben Garrison and others.

NEW LONDON, WIS.—The Wisconsin Telephone Company is making arrangements to build an exchange here.

WASHBURN, WIS.—The Bayfield County Telephone Company has been engaged in extending its lines to Bayfield and Houghton, and expects to complete the new line this month. This will give the company toll line facilities to all points on Chequamegon Bay to points along the Wisconsin Central Railroad and to Superior and Duluth.

MILWAUKEE, WIS.—The Wisconsin Telephone Company has just inaugurated service on a new toll line between Abbottsford and Ashland, a distance of 120 miles. During the past year the company has strung 16000 miles of copper wire. Seven telephone exchanges were built and in a number of other exchanges new equipment was installed. The company gained 9500 new subscribers, of which 2500 are in Milwaukee.

Electric Light and Power.

SAN PEDRO, CAL.—The City Trustees have instructed the City Attorney to prepare an ordinance calling for a special bond election for the construction of a municipal lighting plant.

LOS ANGELES, CAL.—J. L. Campbell, of San Bernardino, has submitted a proposition for furnishing this city with electricity. The cost to the city of putting in the plant is placed at $63,000.

CRIPPLE CREEK, COL.—Mayor Schockey advises that arrangements be made at once for the construction of an electric light plant, to cost about $50,000. A committee has been appointed to investigate the matter.

GLASTONBURY, CONN.—L. W. Ripley, of Hartford, is contemplating the erection of a hydro-electric plant at Glastonbury. It is proposed to install four alternating-current generators varying from 50 to 300-kw. These will be driven by probably three wheels, either turbines or of the impulse type, with an auxiliary engine of about 250-hp. It is proposed to build one dam probably of concrete about 115 feet high and 230 feet long, and another dam for storage purposes probably of earth and masonry combined, about 35 feet high and 400 feet long. The power will be used for lighting, for manufacturing purposes and for street railway work. No contracts have been placed as yet.

TAMPA, FLA.—The Tampa Electric Company has decided to proceed at once with the construction of a power house at the mouth of Hillsborough River, to cost about $100,000. Mr. Wells is manager.

CONYERS, GA.—The citizens have voted to issue $10,000 bonds for the construction of an electric light plant.

SAVANNAH, GA.—The Savannah Electric Company has under consideration the extension of its system to Tybee, Ga.

SAVANNAH, GA.—The Director of Public Works, in his annual report, recommends the municipal ownership of an electric lighting plant.

ATLANTA, GA.—The Board of Electrical Control has granted the Georgia Railway & Electric Company permission to lay conduits for the purpose of bringing current from the Bull Sluice plant into the city.

KANKAKEE, ILL.—The Kankakee Electric Light & Power Company will construct a concrete dam here this year to cost about $15,000.

BELLEVILLE, ILL.—The stockholders of the Belleville Gas & Electric Company have elected L. D. Turner, Edward Abend, Henry A. Kircher, George Gauss, M. M. Stephens, R. D. W. Holder and Charles Becker directors for the ensuing year.

ROCK ISLAND, ILL.—There is reported to be a movement on foot here to harness the Mississippi Rapids and use the water power. It is proposed to build a dike 500 feet from the north shore 20 miles up the river and get a 15-foot fall which will develop 20,000 horse-power. Congressman Lorimer is reported to have been here in the interest of the matter.

AURORA, IND.—The city of Aurora wants bids for lighting the city with 75 arcs, as well as incandescent lamps for private consumers. Mr. Eugene Severin is the city clerk.

COLUMBUS, IND.—The General Electric Company is stated to have secured the contract for the electric light plant for $7,033. An engine will now be purchased in open market.

INDIANAPOLIS, IND.—David Wallace, of the Board of Public Works, is interested in a plan to furnish Indianapolis with electric power by building a dam across Eel River in Owen County.

CHICKASHA, IND. TER.—Jas. W. Hockaday, manager of the Chickasha electric light plant, states that from $10,000 to $12,500 will be expended by the company for new machinery.

DAVENPORT, IA.—The Davenport Water Power Company has been formed by F. H. Griggs, Charles Ainley and others to build a canal and develop water power from the Mississippi River.

IOWA CITY, IA.—The Board of Regents of the State University will ask the Legislature for an appropriation of $25,000 to construct a dam below the University grounds to furnish power for the heating and electric plants.

WINFIELD, KAN.—The citizens have voted to issue $134,000 water and lighting bonds.

TOPEKA, KAN.—The City Council is considering the question of making improvements to the electric light plant. E. B. Snyder is chairman of the electric light committee.

LEXINGTON, KY.—W. H. McCorkle is seeking a franchise for an electric light plant.

NEWPORT, KY.—Mayor Helmbold in his message to Council advises a municipal electric light plant.

NEW ORLEANS, LA.—It is reoprted to be the intention of the Consumers' Electric Company to construct an extensive electric plant. Jules Dreyfous is President.

BATON ROUGE, LA.—The Baton Rouge Electric & Gas Company during the next three months will place contracts for a 150-kw, 550-650-volt generator, and a 400-hp steam or gas engine; if the latter, a producer plant also.

BAY CITY, MICH.—The Council has adopted an ordinance providing for the establishment of a municipal light plant.

MARQUETTE, MICH.—The Electric Light and Power Commission has decided to employ a hydraulic engineer with regard to the enlargement of the electric light plant.

AGRICULTURAL COLLEGE, MICH.—Bids are wanted Feb. 3 for constructing a central power house and coal shed at the Agricultural College. Address A. M. Brown, Secretary State Board of Agriculture.

MONTEVIDEO, MINN.—The Montevideo Electric Light & Power Company has secured water rights at Minnesota Falls, and proposes to construct a dam and develop power.

MINNEAPOLIS, MINN.—F. W. Cappelen, City Engineer, has submitted a report to the special council committee on the General Electric Company's franchise. He estimates that the cost of a plant with 1000 arc lights, with a relay capacity of 33 per cent., the lamps to be lighted 3500 hours, or according to the all-night system, at $512,646, provided the plant is located on property already belonging to city; of this the conduit system would require $266,774, the overhead system $105,477, the electrical equipment $37,475; steam equipment, $58,200, and building, $32,000. The cost of operation would be about $87,379 per year.

CANTON, MO.—Bids are wanted Feb. 3 for constructing an electric light plant.

HANNIBAL, MO.—The proposition to issue bonds in the sum of $100,000 to rebuild the municipal electric light plant at this place was carried at the special election held January 11.

GALLUP, N. M.—The Gallup Electric Light Company has been incorporated by Maynard Gunsul and Herbert F. Raynolds, of Albuquerque, and Kenneth K. Scott, of Gallup, with a capital of $50,000.

ITHACA, N. Y.—The matter of placing the electric wires underground is under consideration.

GLENS FALLS, N. Y.—The Village Trustees are considering the application of Frank H. Deal, of Troy, for an exclusive franchise to maintain an underground conduit system.

SCOTTSVILLE, N. Y.—The Wheatland Power Company, of Scottsville, has been incorporated with a capital of $20,000. Directors: I. W. Salverds, of Scottsville; M. E. Lewis and H. C. Brewster, of Rochester.

GRANVILLE, N. Y.—The Granville Electric Light & Gas Co. is reported to have acquired water rights at outlet of Lake Saint Catherine near Granville. It is the purpose to dam the lake and use the fall to generate electricity for lighting and power. F. D. Pember is president.

POMEROY, OHIO.—Bids are wanted Feb. 2 for $18,929 bonds, $4466 to be used for lighting purposes. Abe A. Massar is village clerk.

WILLIAMSBURG, OHIO.—This town will sell at private sale $12,000 electric light and town hall bonds. Chas. Hoffman is village clerk.

WILMINGTON, OHIO.—The Wilmington, Water & Light Company has been organized under the laws of New Jersey to establish a lighting plant in Wilmington.

MONROEVILLE, OHIO.—The financial condition of the municipal lighting plant is in bad shape and in consequence the arc lighting department of the plant has been closed down, leaving the town in darkness.

CINCINNATI, OHIO.—The Hamilton-Otto Company will spend $200,000 in improvements to its electric lighting plant. It is the intention to install sufficient equipment to provide for handling both the lighing and street railway systems in Hamilton if necessary.

COLUMBUS, OHIO.—An ordinance is to be introduced in the council to regulate the price of electricity for lighting furnished by all the companies operating in the city. It is proposed to make the limit 7 cents per kilowatt. At present some of the companies are charging 12½ cents.

XENIA, OHIO.—D. M. Stewart and Charles Darlington, of Xenia, have had estimates prepared on the cost of a lighting plant of sufficient size to illuminate the city and furnish power for general lighting and manufacturing purposes. They are organizing a company for the purpose of erecting a plant.

WILKESBARRE, PA.—The Council has granted the Ashley Electric Company a franchise to furnish light in this city.

BRADDOCK, PA.—The Council has provided for the appointment of a committee to inquire into the cost of an electric light plant.

MAHANOY CITY, PA.—The People's Light, Heat & Power Company, of Mahanoy Township, has been organized with D. M. Graham, president, and A. B. Carney, secretary.

SELINSGROVE, PA.—The Borough Council has decided to accept a proposition from Mr. Callahan, of Sunbury, to light the town with electricity. The plant will be installed here at once.

ELLWOOD CITY, PA.—It is stated that the Manufacturers' Light & Heat Company, of Pittsburg, will, during the year, make extensive improvements on the lines of its Ellwood City division.

PHILADELPHIA, PA.—The Department of Health has approved plans for a light, heat and power plant for the Municipal Hospital, to cost about $125,000. Geo. W. Sunderland is assistant director.

NEW CASTLE, PA.—Wylie McCaslin, chairman of the Police Committee, has been instructed to procure the services of an electrical engineer to give estimates as to the cost of construction and operation of a municipal electric light plant.

ALLENTOWN, PA.—In his annual message to City Councils, Mayor Lewis advocates the installation of municipal electric light plant. The city is now paying to the Allentown Electric Light & Power Company over $20,000 a year for street lighting, and it is claimed that a municipal plant could be installed by the city at a cost much less than that. The Mayor's idea is to operate the lighting plant in conjunction with the pumping station.

SCRANTON, PA.—The Delaware, Lackawanna & Western Railroad Company has just completed a big power plant at the Hampton mine in the Keyser Valley. The plant is equipped with 15 Babcock & Wilcox water-tube boilers of 325 hp each, which evaporate 400,000 gallons of water per day on a consumption of 175 tons of coal. The electrical equipment will include five 500-kw Curtis turbo-generators, two of which are now in operation. Electrical energy will be transmitted at 2300 volts (alternating current) to various mines owned by the company, where it will be transformed into direct current at a lower voltage by means of rotary converters. The power is used for lighting and power purposes at the mines.

AIKEN, S. C.—The Board of Directors of the Carolina Light & Power Company has authorized W. E. Moore, of McConnellsville, Pa., to negotiate for a $20,000 turbine plant for the local electric light system. Mr. Moore is now in New York for the purpose.

WATERTOWN, TENN.—Prominent business men here are reported to be discussing the construction of an electric light plant.

McGREGOR, TEX.—The power house of the McGregor water and electric light plant has been destroyed by fire.

WACO, TEX.—The City Council is considering the employing of an expert to make an estimate of cost of a municipal electric light plant.

DALLAS, TEX.—A resolution has been passed in Council and referred to Committee with instructions to investigate the advisability of constructing a municipal electric light plant.

SALT LAKE CITY, UTAH.—Among the improvements contemplated by the new Utah Light & Railway Company is the construction of a reserve steam plant, which will cost about $250,000.

DAYTON, WASH.—Jas. A. Ralph and Nicholas Codd have purchased the electric light plant here for $40,000.

EVERETT, WASH.—The Everett Development Company has begun work on a water and electric plant on May Creek. There is a head of 2000 feet, and about 10,000 horse-power will be developed.

OLYMPIA, WASH.—The Olympia Light & Power Company has executed a mortgage for $100,000 in favor of the American Loan & Trust Company, of Boston. The money is to be used in the enlargement and improvement of its works and equipment.

SHINNSTON, W. VA.—The Shinnston Light & Water Co., has been incorporated with a capital of $10,000. L. J. Howard is one of the incorporators.

RICHWOOD, W. VA.—The Richwood Light & Power Company, of Richwood, has been formed with $25,000 capital, by Richard M. Dyer, M. E. Dyer, of Cumberland, Md.; P. J. Dyer, of Weston, W. Va., and others, to construct an electric light and ice plant.

SHELL LAKE, WIS.—This city is considering the construction of water works and an electric light plant.

EAU CLAIRE, WIS.—It is reported that the Council will consider the feasibility of a municipal lighting plant.

ELKHART LAKE, WIS.—The electric light plant which has been idle for the last three months has been purchased and put in operation by Dr. Brickhauer.

PORTAGE, WIS.—It is stated that the Chicago, Milwaukee & St. Paul road will put in an electric light plant and pumping station of its own in this city. The road objects to the price it is paying for light and water.

FT. D. A. RUSSELL, WYO.—Bids are wanted Feb. 13 for lighting the Post here by electricity, including wiring of buildings and grounds, furnishing and installing fixtures, arc lights, etc., and necessary electrical current. Address Capt. W. S. Scott, Q. M., U. S. A., Cheyenne.

CATORCE, MEX.—An electric light plant is to be installed at the Dolores Trompeta mine, situated in this district.

CITY OF MEXICO, MEX.—The city council has appropriated $348,000 for providing the city with electric lights during the year 1904.

LA PIEDAD, MEX.—Jesus Avalos will soon commence the construction of a large electric power plant on the Lorma River, near here. He proposes to provide electric lights and power for several towns in this section and to furnish power for the operation of manufacturing concerns.

WOODSTOCK, ONT.—The citizens have voted to issue $25,000 bonds for improvements to the lighting plant.

OTTAWA, ONT.—A deputation representing the large electrical interests of Niagara Falls has interviewed the Ontario Government with a view of obtaining permission to export electrical energy from Canada to the United States. The International Railway Company, which includes the Gorge line and the Niagara Falls Park & River line, has not sufficient power, and its representatives desire that the Canadian power companies shall have the right to export power. It was, however, thought doubtful whether the government, under the Constitution, could allow the exportation of power and the matter has been taken under advisement.

OTTAWA, ONT.—The Ontario government has obtained information from provincial cities, towns and villages regarding municipalities conducting reproductive undertakings, covering a period of 1898 to 1902. The electrical statistics compiled from the returns sent in, show that electric lighting was a losing business in cities, but successful in towns and villages. The following figures, in regard to electric undertakings, are for the average of the years 1898 to 1902: There were 3 cities, 23 towns and 8 villages owning and operating electric light plants in the province. The capital provided for electric lighting by cities amounted to $81,573, by towns $537,355 and by villages $121,565. The average annual income from electric lighting plants in cities was $7,613, with working expenses at $18,418; the average income for towns was $134,803, and working expenses $107,581, and in villages the average income was $11,247 and working expenses $7,893.

OTTAWA, ONT.—According to the report of the officers carrying out the electric light inspection act, there were, last year, 324 plants in the Dominion, with 14,780 arc lights and 1,212,861 incandescent lights. Taking the arc light as equal to 10 incandescent lights, the country had on the 30th of June last, 1,360,661 lights in use. This is an increase of 236,865 lights in the twelve months, or over 21 per cent. The increase since 1898 in arc lights has been 42 per cent and 161 per cent in the number of incandescents. The province of Ontario has 203 of the 324 plants in use. It has considerably more than one-half the total number of arc lights and 47 in each hundred on the incandescents. The province of Quebec has 53 plants, 3,853 arc lights and 409,503 incandescents. The plants in Quebec, however, are much larger than those of Ontario, the average of Quebec's 53 plants being 15,000 arcs and incandescents, and that of Ontario's 203 plants being 3,215 arcs and incandescents. The largest single plant in the Dominion is that of Toronto with its 170,000 lamps, arcs being reckoned at 10 incandescents. The next largest is that of the Lachine Rapids Company, Montreal, with 158,503, and the third in size is that of the Ottawa Electric Company, Ottawa, with 111,927 lights. All the other provinces have made considerable progress, but British Columbia shows the largest proportional increase of any of the divisions of Canada.

THE ELECTRIC RAILWAY.

LOS ANGELES, CAL.—Articles of incorporation have been filed in San Bernardino County for the Holton Interurban Railroad Company, with its principal place of business in Redlands. Its capital stock is $200,000, of which amount $12,500 has been subscribed. The directors are W. F. Holt, C. S. Lombard, C. A. Barker, A. G. Hubbard and M. M. Phiney.

CHICAGO, ILL.—Judge Grosscup has ordered an examination into the financial status between the Chicago Union Traction Company and its underlying companies. Henry W. Bishop, master in chancery, was selected by the court to conduct the examination.

SHELBYVILLE, IND.—Motormen and conductors on the Indianapolis, Shelbyville & Southeastern Traction Company were given an increase in wages from 18 cents to 20 cents an hour beginning with the new year. The working hours were shortened from eleven to nine and one-half.

LEBANON, IND.—Wallace B. Campbell, promoter of the Anderson-Lebanon Traction Railway has been granted a fifty-year franchise to build into this city. Mr. Campbell has secured franchises in all the cities along the proposed line, and will now turn his attention to securing the right of way. He will soon organize the company, and says the money to build the road is ready.

GLOUCESTER, MASS.—The Massachusetts Electric Companies are installing a new high-tension system for supplying current to all the lines included in their properties. There will be three steam turbine alternating-current central stations, which will supersede about 13 engine-driven direct-current stations scattered over the territory served. The lines north of Boston, including those of the Gloucester division, now receive power from 10 separate stations, 5 of which will be replaced by one steam turbine station, aggregating 9000 hp, and located at Danvers. The southern division is now operated from 11 direct-current stations, which will be superseded by 2 steam turbine stations, one of 1200 hp at Fall River, and one of 15,000 hp at Quincy Point.

WOODSTOCK, N. B.—An electric railway between Fredericton and Woodstock, New Brunswick, is projected. American capitalists will be interested in the enterprise. The new line will be used for carrying freight and passengers.

PRINCETON, N. J.—Surveys have been completed for the proposed electric railway between Princeton and Somerville, or Bound Brook, and the business arrangements are being taken up. It is understood that allied interests have a traction charter under which the road can be built, but T. G. Kitchin, of Trenton, N. J., who has represented the promoters in several business transactions, says that a steam railroad charter will be used. The road will be about 17.8 miles long, and will connect at its northerly terminus with a line to be built between Somerville and Morristown, if the present plans are carried out.

MINEOLA, N. Y.—The Cleveland Construction Company, of Cleveland, Ohio, is placing many of the contracts for the equipment of the new power station of the New York & Long Island Traction Company, which is to be erected at Rockville Center, on the line of the road. The company is now extending its South Shore division from Rockville Center through Linbrook, Valley Stream, Rosedale and Springfield to the terminal of the Kings County Elevated Railroad in New York City.

TOLEDO, OHIO.—The Toledo & Fort Wayne Railway Company has been incorporated at Columbus with a capital stock of $100,000.

NORTH AMHERST, OHIO.—The Lorain & Southern Electric Railway Company has been organized here to build an electric railway from Lorain to Oberlin through this place. The distance is 15 miles. The road will be used for hauling freight and stone trains, as well as for passengers, electric locomotives supplying the motive power. It is stated that the Westinghouse Company will furnish the electric locomotives and entire electrical equipment.

OGDEN, UTAH.—It is stated that a deal is pending for the acquisition of the Ogden street railway system by the Consolidated Light & Railway Company, of Salt Lake City. This would give the latter company control of every foot of electric railway in the state. The local management has decided upon numerous improvements if the Salt Lake Company does not secure control of the system.

MONTREAL, QUE.—The Montreal Street Railway Company, in strengthening its operating staff is recalling former employes that have been serving with other companies. Mr. Ludger Trudeau, who has been acting as manager of the Street Railway Company of Alexandria, Egypt, has arrived in Montreal to again assume a position with the company he formerly served there. Three years ago Mr. Trudeau became manager of the street railway in Bordeaux, France, and while in that employ he received his appointment to the Egyptian concern.

OTTAWA, ONT.—Canadians are reaching out for electrical enterprises in many foreign fields. A number of Nova Scotia capitalists recently visited the Island of Trinidad and the opportunity there offering proved so tempting that it was decided to take over the tramways in the town of Port of Spain, and operate them upon modern lines. The tramway in question is 12½ miles in length. The company, which has been formed under the name of the Trinidad Electric Company, secured the plant at the figure of $1,200,000. It has already instituted a new plant and has put a Canadian at the head in the person of Mr. F. W. Teale, who was formerly with the Boston Tramway Company.

New Industrial Companies.

THE ELECTRIC TYPEWRITER COMPANY, of Norfolk, Va., has been incorporated. Mr. H. H. Little is president. The capital stock is $50,000.

THE STANDARD LIGHT & HEAT COMPANY, of Jersey City, N. J., has been incorporated with a capital stock of $100,000 by James T. Morgan, Le Roy S. Lewis and Louis G. Morton.

THE ESSINGTON ROTARY STEAM ENGINE COMPANY has been incorporated at Camden, N. J., with a capital of $300,000. The names of the incorporators are Henry C. Essington, James W. Irwin and Almon P. Wint.

THE CIRCUIT-PROTECTING RELAY COMPANY, of Kendall, Orleans County, N. Y., has been incorporated to manufacture telegraph instruments. The capital stock is $3000, and the directors are S. R. Wright, M. J. Storer and John Elliott Morton.

W. H. COVERDALE & COMPANY, of New York City, have been organized to carry on the business of civil, electrical and mechanical engineering, the capital stock being $25,000. The directors are W. H. Coverdale, C. F. Keene and G. C. Atkins, of New York City.

THE ELECTRIC CYCLONE AMUSEMENT COMPANY, of St. Louis, Mo., has been incorporated to operate electrical mechanical devices for amusement. It has a capital stock of $100,000, one-half paid. The incorporators are Edgar P. Voll, J. J. Wehrle, A. E. Hoffman, Myer Morris and John H. Goodfellow.

THE HUTCHISON ACOUSTIC COMPANY, of New York City, was incorporated this week with a capital of $500,000, to manufacture special telephonic mechanisms. The directors are M. R. Hutchison, of New Rochelle; H. B. Babbitt, of Washington, D. C.; and K. M. Turner, J. H. Devlin and J. Shirley Eaton, of New York City.

Obituary.

MR. ERNEST THOMPSON.—We regret to announce that Mr. Thompson, partner in the firm of Nalder Bros. & Thompson, manufacturers of ammeters, voltmeters and various instruments, London, England, died recently, after a long and painful illness. Mr. Thompson had been quite unable to attend to business for about a year, since which time, however, he had undertaken a voyage around the world in the hopes of restoring his health. He was in New York about a year ago. On his return to London, however, and on attempting to take up business, it was found that he was quite unequal to the task, and rapidly got worse. Mr. F. H. Nalder, who is well known in America, as well as in England, will continue the business, and we are sure that many readers of our papers will extend their sympathy to the family and to Mr. Nalder.

MR. W. O. GARRISON.—We noted briefly last week on telegraphic advices the death of Mr. W. O. Garrison, president of the Columbia Incandescent Lamp Company, of St. Louis, and a member of the well-known Missouri family of that name. It is with deep regret that we have thus seen pass away a young man of such ability and sterling worth. He was the eldest son of Daniel E. Garrison and a grandson of the late Oliver Garrison, famous as one of the leaders in building the Missouri Pacific Railroad. He was born in St. Louis 42 years ago, and after graduation went into business there, marrying about 13 years ago Miss Edith Hendel, a granddaughter of the late Jesse Arnott. For several years past he had been prominent in the electrical field, and most highly esteemed by all who met him or knew him intimately. He had been in poor health for a number of months, being confined to his bed since early in September on account of trouble with his leg and hip. The complaint appeared at first to be sciatic rheumatism, but afterwards developed into inflammation, as a result of grippe. The family did not, however, until very recently, take a serious view of the case, as he had been able to conduct the business of the Columbia Company in his wonted vigorous way, while in bed. Just lately, however, he showed a grave weakness of the heart, and this on Sunday evening, January 17, was the direct cause of his death. He was active as well in social as in business affairs, being a member of the Country Club, the Mercantile Club, and other leading social and commercial organizations. His wife survives him. His brother, Mr. A. C. Garrison, formerly connected with the Columbia Company, will again give it his attention and has succeeded to the presidency, to which he will now devote his entire time and attention.

Educational.

A VALUABLE GIFT TO LAFAYETTE COLLEGE.—The Henry W. Oliver chemical and metallurgical library of Lafayette College, Easton, Pa., has received as a gift from a generous friend all the pamphlets, about 3000 in number, belonging to the library of the late Professor Johannes Wislicenus, of the University of Leipsic, Germany. Prof. Wislicenus was a famous chemist. He was a pioneer in the study of lactic acid and led in the work which gave to us our present knowledge of stereoisomerism. This library represents the collection of fifty years of great activity and will be a valuable addition to the Oliver library.

COLUMBIA UNIVERSITY, NEW YORK.—At a recent meeting of the trustees of Columbia University, it was voted to fix the annual fee for tuition in the Schools of Applied Science and in the College of Physicians and Surgeons at $250 from and after July 1, 1904. The annual tuition fee in these schools is at present $200. Since the present fee was fixed the equipment of Columbia University in these departments has been greatly increased, and the number of instructors multiplied. The cost of giving the instruction in applied science and in medicine has steadily grown year by year and is now not less than twice the amount received from fees for tuition. The tuition fee at the Massachusetts Institute of Technology is already $250, and the fee for New York students who attend the Stevens Institute of Technology at Hoboken is $225. The per capita cost of instruction at Columbia is believed to be greater than that at either of the institutions mentioned.

THE AMERICAN SCHOOL OF CORRESPONDENCE has adopted a method of advertising which, even if it is profitable to them, is a very good thing for students of electricity. As readers of the technical periodicals have doubtless noted, that institution has arranged under one cover four of the forty-five text books which it uses in teaching its course in Electrical Engineering, and is selling the whole for seventy cents. The four chosen are: "Elements of Electricity," and "The Electric Current," both by L. K. Sager, S. B., LL. B.; "Electric Wiring," by H. C. Cushing, Jr.; and "Storage Batteries," by F. B. Crocker, E. M., Ph. D., Professor of Electrical Engineering at Columbia University. They are all crisply and concisely written and well condensed. There are incorporated in the volume several tables and a whole lot of reference data, which would be of considerable value to one engaged in any electrical line. The section on Storage Batteries, by Prof. Crocker, gives just the sort of storage battery information and tells it in just the sort of way that will reach the practical telephone man, who should at least have a good idea of this appliance which is now so common in these days of central energy. There are 256 pages in the volume.

Personal.

MR. A. G. BRIGGS, of Alameda, Cal., has now been appointed superintendent of the Merced Falls, Cal., Gas & Electric Company.

MR. J. H. ROSENTHAL, managing director of Babcock & Wilcox, Limited, of London, has sailed for home after a brief sojourn in the States.

MR. GEORGE WESTINGHOUSE is a passenger on the North German Lloyd liner *Kaiser Wilhelm II*, which left New York for Europe Jan. 26.

MR. H. HINE, president of the Guanajuato Electric Light & Power Company, Mexico, is expected back in New York next week from Colorado Springs.

GEORGE A. FERNALD & COMPANY, of Boston, Mass., has bought a controlling interest in the Stoughton, Mass., Gas & Electric Light Company.

MR. ROBERT W. BLACKWELL, of the British electrical engineering and contracting firm of Blackwell & Company, Limited, has sailed for Europe after a short visit to the States.

MR. ALBERT E. DOE, JR., formerly with Norcross Bros. Company, of Boston, has been appointed New England representative by the Thomas H. Dallett Company, of Philadelphia.

MR. H. F. PARSHALL, the well-known American electrical expert, who has been located in London for some years past left New York Jan. 26 for Europe on the *Kaiser Wilhelm II* after a brief stay on this side.

MR. E. A. CAROLAN, manager of the London offices of the General Electric Company, and a director of the British Thomson-Houston Company, Limited, has sailed for Europe after several weeks' visit to this side.

MR. W. S. CHASE, sales manager of the National Acme Manufacturing Company, of Cleveland, Ohio, has taken passage from New York for England and the continent on a business trip which will last about two months.

REAR ADMIRAL CAPPS, Chief of the Navy Bureau of Construction and Repairs, was given a reception at the Engineers' Club last week, when there was a large attendance in spite of the wretched weather. Many electrical men were present.

MR. H. W. SPANG, the veteran electrician and lightning-rod expert has contributed to the *American Gas Light Journal* an interesting article on the unscientific electrical engineering that results in the electrolytic destruction of underground pipes.

MR. CHAS. E. COLLINS, the hydraulic engineer, the Drexel Building, Philadelphia, is preparing plans for the Hoosick River power plant of the Schaghticoke Electric Power Company, of Schaghticoke, N. Y., which proposes to develop about 3500 hp.

MR. JOHN C. McDONALD, wire chief of the New York Telephone Company at the Tremont exchange, has worked out a "safe" third rail method or attachment which he is now having patented. He has rigged up a 30-foot track at his home and may presently experiment on the Interborough tracks.

PROF. A. G. BELL has arrived from Italy with the body of James Smithson from Genoa, where it has lain many years. It was taken on the U. S. S. *Dolphin* to Washington, where it has been interred at the Smithsonian Institution, which Mr. Smithson gave to this country. Mr. Smithson died in 1829.

MR. JOHN E. STARR, for some time past connected with Arthur Koppel, 66 and 68 Broad Street, New York, is about to leave for Russia. He will establish himself at Revel, on the Baltic Sea, where he will conduct an agency for the handling of American electrical equipment and supplies, also machine tools.

PROF. J. BLONDIN has resigned as editor of *Eclairage Electrique* to become editor of a journal shortly to be issued, to be named *Revue Electrique*, and to be published by Gauthier-Villars. The journal will resemble the Digest in plan, its purpose being to review foreign current electrical periodical literature.

MR. ROBERT H. HASSLER, formerly with the Westinghouse Electric & Mfg. Company and more latterly electrical engineer with the Waverly electric automobile interests, etc., has now become connected with the Marion Motor Car Company, of Indianapolis, which is going into the gasoline automobile field.

MR. FRANCIS F. COLEMAN contributes to the *Manufacturers' Record*, of Baltimore, Md., a very interesting article on the recent electrical development of the South, citing a great many instances of new plants, new work, etc. The prosperity of that large and important region has stimulated electrical enterprises of all kinds.

MR. F. A. LA ROCHE, the well-known electrical manufacturer and engineer, has of late found himself overwhelmed with the new business work due to his connection as manager with the American Darracq Automobile Company. He is, however, still deeply interested in electrics when not winning races or challenging competitors to produce as good machines.

MR. JAMES F. CUMMINGS, who recently secured the contract for the laying of the conduit for the St. Petersburg municipal telephone and telegraph lines, is now in Cincinnati, Ohio. He is expected in New York early next week at the Hotel Imperial. The conduit is being manufactured at the Raritan, N. J., plants of the National Fireproofing Company. Further Russian contracts are pending.

PROF. CURIE and his wife deny the statement that they intend to visit America. It is a pity they cannot come over. They would receive a royal welcome from admiring and appreciative citizens of this country in general, and from the scientific world in particular. There is no jealousy here in regard to their splendid work, which has added so greatly to the scientific glory of France.

MR. A. N. BRADY, the electric lighting magnate is largely interested in a theatre at Albany, N. Y. When he heard of the Iroquois Theatre fire in Chicago, he went to the Commissioner of Public Safety and insisted that it should be closed until brought thoroughly up to the best insurance standards of the time. It is a pity there are not more theatre owners as public spirited and prompt to act.

MR. RALPH D. MERSHON, the consulting electrical engineer, is at an early date to give the New York Electrical Society an address on the subject of the gas engine for central station work. This will be a very interesting topic for a great many of the members. Mr. Mershon has made an intimate study of the gas engine and takes an opportune time to give publicity to his views and ideas.

MR. JAMES ROSS, of Montreal, president of the Mexican Light & Power Company, Limited, which is building a huge plant at Necaxa to generate power for transmission to Mexico City and the El Oro mining district, has left for the southern republic in order to inspect the progress made in the work. He is accompanied by Mr. F. L. Wanklyn, formerly vice-president and general manager of the Montreal Street Railway.

MR. RUDOLF WIESER has been commissioned by the Mexican-American Company, 49 Wall Street, New York, to look over the ground with a view to constructing an electric railway between Guadalajara and Lake Chapala—the Saratoga of Mexico. The distance is about 40 miles. The Mexican-American Company also proposes to install some lighting plants in the State of Jalisco. E. H. Talbot is president of the company.

MR. HERBERT LAWS WEBB, who has been away from this country for several months, is again in New York for a time. He has been doing considerable work in England as a telephone expert and consulting engineer. It will be remembered that he was connected for some years with the New York Telephone Company. Mr. Webb is however well known in England, the family being an old one in electrical affairs. He is a nephew of Sir W. H. Preece, F.R.S.

MR. A. M. MATTICE, who is prominently connected with Westinghouse interests and is the chief engineer of the Westinghouse Machine Company, received a high compliment from President Kafer, of the Engineers' Club, last week, in a speech before that body. Mr. Kafer, who was at one time professor of mathematics at the Naval Academy, spoke of Mr. Mattice as by far the most brilliant student there in many years, if not indeed during the whole existence of the Academy. Mr. Mattice for some time was an assistant to Admiral Melville.

MR. CHARLES T. YERKES has sailed for England on the *Kaiser Wilhelm II*, after an extended visit to this side. Shortly after his arrival in London it is expected that the contract will be awarded for the motor equipments to be used in the extensive underground and surface electric traction system which the Underground Electric Railways Company of London, Limited, of which Mr. Yerkes is chairman, and in which the Speyers, the New York Life and Mutual Assurance and other prominent American interests are largely concerned. The motor equipment contract will represent an expenditure of some $3,000,000.

MR. W. C. GOTSHALL.—At the annual dinner of the Lehigh University Club, of New York, at the New York Athletic Club, last week, W. C. Gotshall, president of the Port Chester Street Railway Company, told the guests that Lehigh should establish a chair of railroad engineering or transportation because of the great demand for men schooled in the intricate knowledge of railroad building and operation that has grown up in the past decade. The universities to-day, said Mr. Gotshall, do not appreciate the necessities of every day commercial life. Mr. C. O. Mailloux, who spoke eloquently on the same general topic, has been one of the lecturers lately at Lehigh, with much acceptability.

PROF. A. H. PHILLIPS.—In recognition of the service of Prof. Alexander H. Phillips, of the chemistry department of Princeton University, "the first American mineralogist to extract radium from an American ore," a gift of twelve and a half grains of radio-active barium chloride will be presented to the university this spring. Following the recent extraction of radium from carnolite by Prof. Phillips, a company has been formed in Buffalo, N. Y., for the purpose of producing it at a reasonable price. The first product turned out will be donated to the university by Stephen J. Lockwood, a Princeton graduate and organizer of the Buffalo Company.

MR. T. H. BAILEY WHIPPLE has reurned to the Sawyer-Man Company, and the position which he left last summer in order to take a part in the reorganization of the sales department of the Nernst Lamp Company of Pittsburg. Mr. Whipple is an old hand in the commercial end of the electric lighting field. He was general sales agent with the Buckeye Electric Company of Cleveland, Ohio, and held a similar position with the Jandus Electric Company which was an off-shoot of the Buckeye Electric Company. During his connection with these two companies he established most of their agencies throughout the United States. Early in 1903 Mr. Whipple went to the Sawyer-Man Electric Company, with which he remained until he was called as above noted to the Nernst Lamp Company.

Trade Notes.

THE JEFFREY MANUFACTURING COMPANY, of Columbus, Ohio, through its connection with the Ohio Malleable Iron Company, of the same place, is now in the field soliciting orders for high grade malleable castings.

LAMP TESTING BUREAU.- It is proposed by the Lamp Testing Bureau, of New York City, to change its name, and Mr. John W. Lieb, Jr., its president, has given legal notice of the intended plan to call it the Electrical Testing Laboratories.

ASBESTOS THEATRE CURTAINS.—We have received from the H. W. Johns-Manville Company samples of the cloth used by it in its excellent asbestos theatre curtains, accompanied by a leaflet on the subject, which shows actual tests being made in a New York theatre, and gives some most interesting data on this important subject.

THE INTERNATIONAL BRASS & ELECTRIC COMPANY, 76 Beekman Street, New York, has issued its 1904 catalogue of the line of goods manufactured by it. The catalogue contains illustrations and price lists of induction coils, automobile coils, sparkers, switches, connectors, etc. The company manufactures these articles and many others, and carries goodly sized stocks.

THE AMERICAN WATER SOFTENER COMPANY, of Philadelphia, has opened a branch office in the Outlook Building, Columbus, Ohio, in the immediate charge of Mr. W. H. P. Fisher, general sales agent for the company, and Mr. A. C. Tomlinson, manager of the Columbus office, who for some time has been the assistant manager of the Philadelphia office.

THE CENTRAL ELECTRIC COMPANY, Chicago, is starting in 1904 with renewed enthusiasm to push the sale of D. & W. enclosed fuses and safety devices. The company makes the statement that the popularity of D. & W. material has been steadily growing and with a constantly widening field ahead there is every reason to believe that the coming year will witness very largely increased sales.

INDICATOR WORK TAUGHT BY MAIL.—The Indicator Instruction Company, of Scranton, has been formed to give indicator instruction by mail under Mr. A. C. Lippincott, well known as an indicator expert and the inventor of the Lippincott planimeter for measuring indicator cards. Everything relating to indicator work will be taught, including the subjects of the planimeter, reducing motions, care and repair and testing of indicators. Indicators will be loaned to the students of the course.

THE BEARDSWORTH ENGINEERING & MACHINERY COMPANY, Cleveland, Ohio, has been formed to act as electrical engineer and selling agent for electrical equipment. The company will make a specialty of selling and re-installing complete second-hand power plants that are fully guaranteed by those who wish to dispose of the same. It has a number of complete plants for sale in various parts of the country. Parties having steam and electrical equipment too small for their present requirements can make advantageous exchanges through this company.

PELTON WHEELS.—A large order for Pelton water wheels is being completed for the Columbia Improvement Company, near Tacoma, Wash. The installation consists of four Pelton units, aggregating 31,000 hp operating under an 850-foot head. These are the largest water wheel units in the world, with the exception of those at Niagara Falls, and demonstrate the abilities for handling especially large orders. An 88-page illustrated catalogue containing complete data in reference to hydraulic power is sent free on application to the Pelton Water Wheel Company, 130 Main Street, San Francisco, or 141 Liberty Street, New York.

NEW STURTEVANT PLANT.—One of the features of the new plant of the B. F. Sturtevant Company, at Hyde Park, Mass., peculiarly indicative of the permanent character of the new works now under construction, is the steam tunnel 4½ feet in width and 6½ feet high, extending from the power plant to the most remote part of the manufacturing buildings, a total distance of about 800 feet. This tunnel, which is of concrete construction, will not only accommodate all of the steam piping, but also the electric wires for power, light, telephone, standard time clock, and other service, together with oil, hot water and other pipes for general distribution to the various buildings of the plant. None of these features of the equipment will be carried above ground at any outdoor point. While the expense of such an installation is necessarily large, the convenience of access for changes and repairs will in the future much more than offset any fixed charges thereon.

THE SPRAGUE ELECTRIC COMPANY'S New York office and Watsessing factory forces held their annual bowling tournament and banquet at Smith's Hotel, Roseville, N. J., on Jan. 16, 1904. That it was a grand success goes without saying. Besides the "boys" several of the officers of the company and many heads of the departments were present. Four bowling matches arranged on a "sliding scale basis" were rolled. The representatives of the office force came out victorious in all of the matches after hard-fought battles with their opponents, the representatives of the factory, who acted as hosts on this occasion. It may be noted that although they were beaten in the matches, it was the consensus of opinion of all present that as hosts, Mr. Charles Noll and his confreres were without equals. After the matches everybody sat down to a banquet and tackled the uniquely gotten up bill of fare in such a manner as if a thing as indigestion had not been heard of by any of the party. After the coffee had been served and the last "fuse" had been "blown," the toasts were "thrown into circuit." The voltage of the themes of these toasts was very high and the "circuit breakers" of laughter were continually being "tripped." Mr. Issertel, of the New York office, acted as toastmaster. He is the walking delegate of the Toastmasters' Union, and holds his job on merit.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED JANUARY 19, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., N. Y.]

749,716. RAIL CONTACT SHOE; George W. Brady and Lawrence R. Jones, Wheaton, Ill. App. filed Jan. 26, 1903. The shoe has two diverging sides adapted to engage the corners of the rail where least ice is supposed to form.

749,775. ELECTROSTATIC RELAY; Dan. La Cour, Copenhagen, Denmark. App. filed Feb. 7, 1903. An electroscope charged from a local source of electricity effects by its movements the closing or interruption of an electric circuit.

749,785. BATTERY-PLATE; Oskar Frank, Detroit, Mich. App. filed May 2, 1903. (See page 225.)

749,795. TROLLEY STAND; James Kermath, Detroit, Mich. App. filed Oct. 9, 1903. Details of the stand whereby it is supported close to the top of the car and offers no hindrance in passing under viaducts.

749,798. CENTRAL-ENERGY TELEPHONE SYSTEM; Kempster B. Miller, Chicago, Ill. App. filed Dec. 19, 1900. (See page 226.)

749,813. PORTABLE X-RAY APPARATUS; Eugene W. Caldwell, New York, N. Y. App. filed Jan. 16, 1903. An organization of the complete outfit with parts arranged for quick adjustment.

749,814. RELAY DEVICE; John P. Downs, Cleveland, Ohio. App. filed May 7, 1902. Details.

749,824. TELEPHONE-EXCHANGE; Nils Emel Norstrom, Chicago, Ill. App. filed Nov. 23, 1900. (See page 226.)

749,835. ELECTROMECHANICAL SWITCHING MECHANISM; Walter J. Bell, Los Angeles, Cal. App. filed May 29, 1903. A motor to move a switch point is connected and disconnected by a clutch controlled by an electro-magnet.

749,842. BURGLAR ALARM FOR SAFES; Henry R. Cassel, London, Eng. App. filed May 3, 1902. A pressure of air is maintained in the safe and a circuit closer therein is actuated when the pressure is altered.

749,843. PROCESS OF EXTRACTING PRECIOUS METALS BY ELECTROLYSIS; Henry R. Cassel, New York, N. Y. App. filed Oct. 25, 1902. (See page 225.)

749,844. APPARATUS FOR EXTRACTING PRECIOUS METALS BY ELECTROLYSIS; Henry R. Cassel, New York, N. Y. App. filed Oct. 25, 1902. (See page 225.)

749,855. PROCESS OF PRODUCING ELECTRODES FOR STORAGE BATTERIES AND ELECTRODE; Frederick A. Feldkamp, Newark, N. J. App. filed May 19, 1903. (See page 225.)

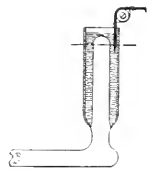
749,867. METHOD OF SECURING ELECTRIC WIRES; Alexander Kline, Jersey City, N. J. App. filed March 31, 1902. The tie-wire used to fasten a conductor in the groove of an insulator is a flat strip which can be wound around the conductor without the use of tools and thus prevents the liability of damaging the conductor by the plier.

749,916. TROLLEY FOR OVERHEAD ELECTRICAL CONDUCTOR SYSTEMS; Eugenio Cantono, Rome, Italy. App. filed Aug. 3, 1903. Details.

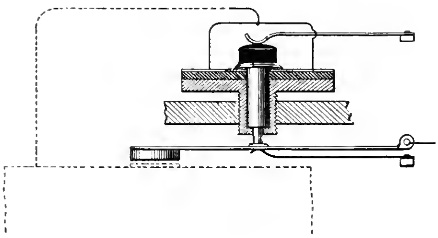
749,919. HANDLE FOR SNAP SWITCHES; Charles A. Clark, Hartford, Conn. App. filed Jan. 3, 1903. The handle contains an internally threaded movable bushing held telescopically by a spring; when it is screwed upon the spindle of the switch, the tension of the spring holds the cap, if it is a surface-switch, or the plate, if it is a flush switch, tightly in position.

749,939. RAILWAY SIGNALING APPARATUS; John F. Mickey, Frank T. Bailey, and Joseph J. Noppenberger, Baltimore, Md. App. filed Aug. 1, 1903. Details.

749,949. INDICATING DIAL FOR SNAP ELECTRIC SWITCHES;



749,999.—Electrode for Electric Tube Lamps.



750,041.—Vibratory Circuit Controller.

Charles G. Perkins, Hartford, Conn. App. filed Oct. 29, 1903. The dial is secured to the spindle sleeve by means of lugs engaging notches in the dial, the engagement being accomplished by an edgewise movement of the dial.

749,952. LAMP SOCKET; Duny A. Schutt, Peru, Ind. App. filed Jan. 28, 1902. Details.

749,977. TELEPHONE-HOOK SWITCH; Ernest E. Yaxley, Chicago, Ill. App. filed June 12, 1901. (See page 226.)

749,982. ELECTRICAL SIGNALING SYSTEM; Henry P. Clausen, Chicago, Ill. App. filed Dec. 19, 1901. A circuit arrangement whereby a telephone signaling lamp will always light up and respond to a signal regardless of whether the circuit of the lamp is closed for some time or only for an instant.

749,988. CABLE CLIP; Otto C. Hoffman, Chicago, Ill. App. filed July 31, 1902. A strap with a novel form of clamping buckle on the end.

749,989. CABLE CLIP; Otto C. Hoffman, Chicago, Ill. App. filed Dec. 8, 1902. A modification of the preceding device.

749,998. ELECTRIC TUBE LAMP; Daniel McF. Moore, Newark, N. J. App. filed Jan. 22, 1903. An electrode for a tube-lamp consisting of a coating of conducting material spread upon the inner surface of the tube and in intimate connection with a leading-in wire.

749,999. ELECTRODE FOR ELECTRIC TUBE LAMPS; Daniel McF. Moore, Newark, N. J. App. filed Feb. 26, 1903. The end of the tube where the connection is made is placed in a holder containing mercury which operates as the conducting cap and avoids using an adherent coating of graphite.

750,012. FIRE ALARM MECHANISM; Leonidas G. Woolley, Kenton, Ohio. App. filed April 27, 1903. Various details.

750,013. FIRE ALARM SYSTEM; Leonidas G. Woolley, Kenton, Ohio. App. filed July 6, 1903. Relating to the preceding patent.

750,038. ATTEMPERATING DEVICE; Milton H. Shoenberg, San Francisco, Cal. App. filed March 16, 1903. A coupling for controlling the admission of air under the pressure to a dental tool and at the same time for regulating the heating of the air.

750,039. RUHMKORFF COIL; Richard Varley, Providence, R. I. App. filed Aug. 21, 1903. The circuit is broken at the vibrator by the joint action of the core of the coil and an auxiliary magnet, the entire vibrator is also bodily removable, being held in place by spring-clamps.

750,040. VIBRATORY CIRCUIT CONTROLLER; Richard Varley, Providence, R. I. App. filed Oct. 19, 1903. The vibrator makes contact with three different points on the back stroke, thus ensuring a low resistance connection.

750,041. VIBRATORY CIRCUIT CONTROLLER; Richard Varley, Providence, R. I. App. filed Oct. 19, 1903. A construction whereby the primary circuit is opened and closed more than once during each to and fro excursion of the vibrator.

750,093. ELECTRIC-RESISTANCE FURNACE; Alfred H. Cowles, Cleveland, Ohio. App. filed Nov. 20, 1902. (See page 225.)

750,094. PROCESS OF SMELTING MATERIALS AND PRODUCING CARBID; Alfred H. Cowles, Cleveland, Ohio. App. filed Oct. 20, 1903. (See page 225.)

750,098. MOTOR; Bertram J. Delzeit, Philadelphia, Pa. App. filed Oct. 31, 1903. A motor is supplied with current from a number of batteries, successively, the motor itself operating the switching device.

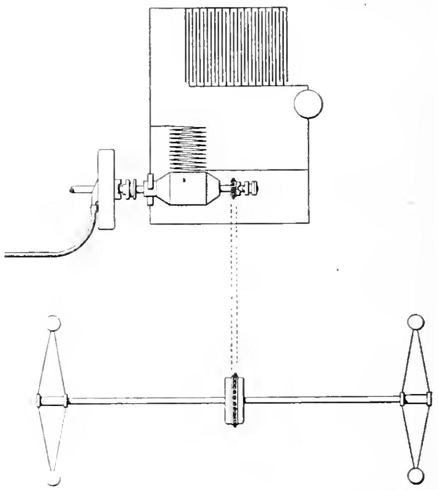
750,102. ELECTRICAL AUTOMOBILE; Thomas A. Edison, Orange, N. J. App. filed Jan. 9, 1903. A turbine steam engine is connected through a clutch with the motor armature shaft, so that by a proper adjustment of the motor circuits, it can be driven as a generator, part of the time, to charge a battery.

750,115. AUTOMATIC ELECTRIC PUMP; Francis L. Orr, Thurman, Iowa. App. filed Sept. 9, 1903. Details.

750,117. ELECTRICAL OPERATED AND CONTROLLED RAILWAY SIGNAL; Robert D. Peters, Knox, Ind. App. filed Nov. 21, 1902. Details.

750,132. ELECTROMAGNET; Illius A. Timmis and Edgar W. Timmis, London, England. App. filed June 19, 1903. A helix having a tapering central cavity and a tapering external surface, the armature having a tapering core and a tapering cylinder or rim.

750,139. ELECTRICAL CONTROLLER FOR RAILWAY CARS; Harlan P. Wellman, Ashland, Ky. App filed Nov. 19, 1903. The exhaust from the



750,102.—Electrical Automobile.

air brake system leads into the controller box to clear the latter of dust and to obtain a muffler effect.

750,150. ELECTRIC FIRE ALARM; Joseph A. Barten and Samuel R. Sneeringer, Philadelphia, Pa. App. filed April 30, 1903. Details.

750,170. METHOD OF ELECTRIC HEATING; Alfred H. Cowles, Cleveland, Ohio. App. filed Nov. 5, 1902. (See page 225.)

750,179. ELECTRIC BLANKET; Charles Foglesong, St. Paul, Minn. App. filed Sept. 14, 1903. A blanket consisting of an asbestos layer and a woolen layer with heating resistance interposed between them.

750,180. METHOD OF CONTROLLING SPARK PRODUCTION; Lee De Forest, New York, N. Y. App. filed June 17, 1903. The method of creating sparks between normally inoperative sparking terminals which consists in increasing at will the condition of ionization of the medium between the sparking terminals.

750,181. DEVICE FOR CLEARING ICE FROM ANTENNAE; Lee De Forest, New York, N. Y., and Walter G. Clark, Seattle, Wash. App. filed June 17, 1903. Apparatus for sending a heating current through the antennae.

750,198. SOCKET FOR INCANDESCENT LAMPS; Owen E. Kenney, Toledo, Ohio. App. filed June 16, 1902. Details.

750,207. ELECTROMAGNETIC BRAKE; John S. Lockwood, Kansas City, Mo. App. filed June 23, 1902. A removable piece acting as a part of the magnet pole and the brake shoe is attached to the core of the magnet.

750,223. ELECTRIC BLOCK SYSTEM; Frederick C. Robinson, Farmington, Me., App. filed Aug. 22, 1903.

750,239. ELECTRICALLY HEATER SOLDERING IRON; William J. Bowen, Cleveland, Ohio. App. filed Aug. 17, 1903. Details.

750,244. FUSE FOR ELECTRIC CIRCUITS; Elwood C. Philips, Chicago, Ill. App. filed Jan. 9, 1903. A fuse plug in which the fusible strip extends around three-quarters of an annular groove, its ends being fixed to proper metallic connections.

THE DINNER AND THE LAMP.

It has been a felicitous idea to associate this year the annual dinner of the American Institute of Electrical Engineers with the twenty-fifth anniversary of the practical perfection and successful introduction of the incandescent lamp, and it was also a happy thought to associate the event next week with the birthday of Mr. Edison, who more than any other man is to be credited with that great accomplishment. The association of the annual dinner with some particular event in electrical history and achievement is, after all, an excellent plan, and we should be glad to see it realized from year to year. This has been a great electrical age and it will be a long time before the Institute runs out of worthy men and events to celebrate.

It seems but yesterday—especially to those of us who have been connected with this utilization of the incandescent lamp—that it was placed in the hands of the public, yet so swift has been its advance and its universal acceptance that already to-day, as compared with electricity, we find gas in the second place in this country as an illuminant. That alone tells the story of the need that existed for such a light and the fitness of the time at which it arrived. Yet twenty-five years ago it was not by any means sure that the incandescent lamp would not itself be worsted by its great rival, the arc lamp; in fact, a great many men of leadership and of force both as inventors and as capitalists, persisted in working at the development of the arc to the neglect of the incandescent. Times have changed and now virtually every central station in the country, besides almost every isolated plant, is on an incandescent lighting basis, while the triumph of the incandescent lamp is most emphatically demonstrated in the fact that in the central station companies of the country the percentage of their income derived from incandescent lighting is 52.4, while arc lighting is only 28.1 per cent. Moreover, all other electric service consisting chiefly of electric motors is 17.7 per cent., and as the success of the motor has been associated also with the incandescent lamp it would appear that to-day the central stations of the country owe 70 per cent. of their income to the little lamp and less than 30 per cent. to the arc. Herein is justification and glory enough for Mr. Edison and for the other great workers in the field of incandescent lighting, and even they, as they look back across the brief space of twenty-five years, must wonder at the wonderful advances of that short quarter century.

DISTRIBUTED LEAKAGE ON TRANSMISSION LINES.

The article by Mr. F. F. Fowle on page 262 of this number relates particularly to the measurement of the insulation of long lines with distributed leakage, by the use of a voltmeter. This problem involves hyperbolic trigonometry for its simplest exposition and computation. The treatment in the article is partly hyperbolic.

There can be no doubt that the direct-reading voltmeter employed as an ammeter is far superior in practical use to a Wheatstone bridge for the measurement of line insulation in telegraphy or telephony. The time has not so long gone by when insulations of telegraph lines used to be measured at regular intervals with a battery and tangent-galvanometer. In these days of dynamos and motors it would be hard to find a place where a tangent-galvanometer would be capable of giving interpretable results; besides which the instrument is relatively slow and insensitive. Nowadays, a common method of measuring insulation of telegraph lines is with a direct-reading voltmeter. By the use of a table, the readings of the voltmeter, when connected between line and a standard voltage, are immediately interpreted into apparent insulation resistances; and multiplying this tabular reading by the length of the line in miles, gives the insulation in megohm-miles. A tabular correction for each line can also be prepared for the effect of distributed leakage, which tends to make the apparent insulation of the line greater than the actual insulation, since the more distant parts of the line are virtually tested for leakage at a reduced pressure, owing to the loss of pressure in the nearer parts.

The formulæ suggested in the article are very unwieldly, and take long computation. Equally correct results may be obtained by shorter methods. The geometric mean of the apparent insulation and conductor resistance of the line gives the surge-resistance, and from this the true insulation of the line follows immediately. Or, when the conductor resistance of the line per mile may be regarded as known, this resistance divided into the product of the apparent conductor and insulation resistances of the line, gives as a quotient the insulation per mile corrected for distributed leakage. As pointed out, however, in the article, the correction for leakage is usually small when the line is short and in good electrical condition. It is only in the cases of relatively long lines of relatively large conductor resistance and poor insulation that the correction for distributed leakage upon the apparent insulation assumes large proportions.

On the Wave Length of Free Vibrations in Wireless Telegraph Antennae.

The conditions and rules affecting electric oscillations in a simple circuit, such as the circuit of a condenser connected to a reactance coil, are fairly well understood. Observations with spark discharges, with oscillographs, and with stationary waves, seem fairly to corroborate the theory. So also in the case of single long wires, or pairs of wires, the waves that run to and fro over their surfaces are fairly well within our mental grasp; but the more complex cases that present themselves when vertical antennæ are linked with local oscillation circuits, are not so thoroughly understood, and experimental evidence in such cases is valuable as a check upon theory. The article by Dr. J. E. Ives appearing on page 260 throws experimental light upon the oscillations of a vertical antenna when connected with a localized oscillation system at its base. It has been known for some time, both from theory and from observation, that although the linear capacity and the linear inductance vary from point to point along a vertical antenna, yet the two quantities always vary reciprocally, and in such a manner that the waves of free disturbance run up and down the antenna with the velocity of light in air. Or, possibly, the reverse mode of thought may be the more logical, and we may say that since unobstructed waves must have the velocity of light in air, the linear inductance and capacity of the antenna at every point are such as will permit of this state of affairs.

Consequently, if we take a 30-meter antenna, a wave will, in a single complete period, run up and down positively and then up and down negatively, making four trips to the complete oscillation, which will last one-tenth of a microsecond in all. It follows from this that four times the antenna height, or 120 meters in the case considered, will be the length of the free emitted wave as it runs off over the earth's surface, provided that there is practically a perfect ground connection at the base of the antenna. When, however, the antenna is loaded by the insertion of an inductance coil at the base, it is known that two things happen: First, there will be an oscillation set up in the complete system of antenna plus load; and, second, there will be oscillations set up in the antenna on its own account, and also in the load on its own account. In other words, the surge-resistance of the antenna being different, in general, from the surge-resistance of the inductance coil, there will be a partial discontinuity, or partial barrier, at their junction, whereby waves passing from one to the other are partially reflected back, instead of going on. The effect is similar to hanging a pendulum of, say, two feet in length, to the bob of a six-foot pendulum. Such a compound pendulum will not only be capable of performing swings as a single system of, say, seven feet in length, but will also vibrate as two independent although mechanically-connected systems, each for itself.

If, however, the surge-resistance of the localized oscillation system be made the same as that of the antenna, then there will be no intermediate discontinuity or reflecting barrier, and the loaded system will oscillate singly, emitting a single series of waves, or waves and harmonics, instead of three associated series of waves, or waves and harmonics. This adjustment of the surge-resistance of the localized system, into equality with the surge-resistance of the antenna, is called tuning the system to the antenna. When the generating system is so tuned there is naturally a marked increase in the power of the waves and frequency of the loaded or compound systems so unified. The illustrations in Dr. Ives' article clearly indicate the effect of loading the antenna on the length of its compound emitted waves. With ten and a half turns of his drum inductance coil, the wave length of the loaded system was double that of the unloaded antenna. With twenty-one turns of the drum the wave length was three times that of the unloaded antenna. When the local oscillation system was tuned to the antenna, the waves in the antenna had an amplitude many times greater than when the antenna and the local system were markedly discordant. It is evident that co-operation between the parts of a wireless generating system is as important as in human affairs; or, that the importance of pulling together, upon the success of a result, is as manifest in the inorganic as in the organic world.

Power Plants as Investments.

The question is often asked by business men as to whether the power transmission plants, now often installed on a very large scale, pay as business propositions. Every one is willing to admit that as engineering feats they are highly successful—but how about the result when the dollar and cent test is vigorously applied? The ultra-conservative are grimly reminiscent of the early days of electric lighting and the doleful tales of failure that are still current. It is a question of very wide scope, this of financial returns, so wide as to be indefinite as would be an inquiry regarding the paying properties of a hardware store, or a saw mill, or a tannery, or a drug store. There is nothing about the electrical business that separates it, as regards its financial features, from any other investment. Its product—power—is always in demand in proper markets, and its manufacturing plant can be erected and operated at an easily ascertainable cost. Building an elaborate plant for a small, uncertain and oversupplied market is simply a piece of financial foolishness like starting an artificial ice factory in Vladivostock or a central heating plant in Aden. The fortune that befell the immortal venture of Lord Timothy Dexter in shipping a cargo of warming pans to Havana cannot be counted upon with regularity in any business—electrical or other. On the other hand, the careful choice of location with reference to raw material and the sale of product, and sound management, will reap their reward as surely in the power business as anywhere else, and very many power transmission plants have given regular and generous returns upon the investment made.

But the strongest claim of electrical power transmission as a practical conservative field of investment lies in the increasing demand for its product on a wholesale scale. The country is rapidly being covered by a network of electric roads, many of them long, and using large amounts of power; the use of electric light is increasing with enormous rapidity; and now electrochemical processes are constantly arising to demand cheap power in very large quantities. Meanwhile, the tendency of fuel prices is steadily upwards, and while in any given year they may seem reasonable, one never knows when they may rise to almost prohibitive figures. With power-using processes steadily on the increase and the cost of fuel very unlikely even to stay down upon its present plane, the utilization of material sources of energy takes on a new importance. A wise manufacturer will to-day adopt electric power even if it shows no present saving over the cost of power from coal, since a great hydraulic plant is a permanent institution with which a long-time contract can be made, looking forward to the average scale of fuel prices for twenty years to come. By making such a contract the interests of both parties are advanced by insuring stability on the one hand, of costs; on the other, of income. Every year the supply of electrical power takes on more and more the character and solidity of a wholesale business. The great plant of the future will not bother itself much about the minute details of distribution, leaving that to be taken care of by local interests, but will devote its energies to cheapening production and to distributing the product over long distances, making long time contracts with its customers, and deriving its revenue from large and reliable sources. So organized, it must rank as an investment of the "gilt-edged" order.

THE REPULSION MOTOR FOR TRACTION.

The papers read at the Institute meeting by Dr. Steinmetz and Mr. Slichter may be taken to represent the line of action of the General Electric Company in the development of alternating-current motors for traction purposes. It has for some time been an open secret that a General Electric single-phase alternating-current motor was under way, and, in fact, perhaps as far along toward commercial application as the alternating motors which have been already announced. The Thomson repulsion motor is one of the most individual and striking of the alternating type and would long ago have been heard from in general power work had it not been possessed of the very characteristics of a series motor which now make it especially useful. Its principle is very simple. Any electric motor must have a magnetic field, wires movable relatively to the field and carrying current, and some means for organizing the resulting torque into continuous rotary motion. In direct-current motors the commutators serve the end last named by systematically reversing the current in the armature coils at the proper times. In the ordinary polyphase induction motor, the workng current being induced in the armature by the field windings is clear out of phase with the magnetization, and is swung into place by the device of providing two or more field windings fed by currents of different phase which serve in cyclic order as transformer and as field coils. In the single-phase induction motor of the ordinary kind there is a compensating phase shift from armature reactance, but a rather unstable one. The Thomson repulsion motor has a simple alternating field, which induces the armature currents, but the latter are organized by short-circuited brushes so as to give a definite polar displacement—as definite as in a continuous-current motor.

As a result of this construction the motor performs well over a wide range of speed, and the machine has, in fact, many of the properties of a series-wound, direct-current motor. Mr. Slichter's curve No. 1 gives a capital idea of the general properties of the repulsion motor as organized for traction purposes. The power factor is much like that of a well-designed polyphase induction motor, holding above 85 per cent. over a wide range of speed. The efficiency curve is likewise steady over a wide range of speed, but is nowhere very high, hardly as high as in common induction motors of similar output. This deficiency may be charged up to the rather large mass of iron which suffers hysteretic loss in a single-phase motor, and is shared by all the types of alternating traction motors on which data have thus far been made public. This deficiency is less marked in the motor compared with a direct-current railway motor in curve 2, but is still conspicuous. Nevertheless, the alternating motor makes a very creditable showing. It is a pity that the power factor curve was not given for this motor, but from the data given it appears to have been respectable. During acceleration the alternating motor has a certain advantage in net efficiency due to the fact that reduced voltage can be obtained with very slight loss of energy, while the direct-current motor suffers from its rheostat. Just how much this advantage will count for in practice it is difficult to say. The repulsion motor shares with the direct-current motor the somewhat problematical advantage of being able to return energy to the line when reversed. It is an interesting property to possess, but has never yet been put to much use in electric railroading. Mr. Slichter's final curves are the computed values for a 175-hp motor, and show properties similar to the others. We regret that all his curves were not obtained from a single machine, as it is difficult to judge results from a torque curve of one motor, an acceleration curve of another, and some other curve of a third; but the general results leave the impression of a pretty useful type of machine with some especial advantages.

In discussing the theory of the motor, Dr. Steinmetz displays his usual deft touch and follows his usual method of treatment. He gives, however, in addition, a very interesting account of the early work of the late Rudolph Eickemeyer on series-wound commutating motors for alternating current. It constituted a wonderfully clever bit of electrical engineering, but was hopelessly handicapped by the prevalent high frequency, which fact should be borne in mind in inspecting Fig. 4 of Dr. Steinmetz's paper. Under present conditions the series alternating motor, as developed, for example, by Dr. Finzi, shows as high a power factor as could reasonably be asked. We refer here to the Finzi motor merely because it is stated to be an unmitigated series machine without any unusual features in the winding. The vital question with respect to all these new alternating motors is the sparking. It is uniformly reported to be small, or negligible, or absent under working conditions. Unhappily, there is no exact method of defining the amount of sparking, and individual judgment in spite of the best intentions is liable to bias. Even the renowned Liebig, who firmly disbelieved in bacterial action, when shown a vigorous colony under the microscope, is said to have closed the eye over the tube, asseverating that he saw no bacteria at all. There seems to be little doubt that the new alternating railway motors have good practical qualities in a general way; that they give ample torque; have very respectable power factors, and efficiency enough to make the distribution via rotary converters look like wilful waste. But there is as yet no good way of settling the sparking question. A few months of actual service in charge of hardened old railway men will bring out the facts with a thoroughness not to be reached in shop tests. And we hope that ere long enough of the new motors will be in service to secure just this sort of trial. If from it they emerge triumphant, it is safe to say that for the future the direct-current railway motor will have to assume the defensive and show cause why it should not be replaced.

The Annual Dinner of the American Institute of Electrical Engineers.

The annual dinner of the American Institute of Electrical Engineers will be held in the main ball room of the Waldorf-Astoria, New York City, Thursday, February 11, 1904, at 7 P.M., precisely. The guest of honor will be Mr. Thomas Alva Edison, and it is expected that an opportunity will be given to meet Mr. Edison at an informal reception, at half-past 6. This dinner will commemorate the twenty-fifth anniversary of the introduction of the incandescent lamp, and will also celebrate Mr. Edison's birthday. Upon this occasion will also be presented the deed of gift of the Edison Medal Association, which has raised a fund of several thousand dollars.

The following guests have accepted invitations: Mr. Ambrose Swasey, president American Society of Mechanical Engineers; Dr. A. R. Ledoux, president American Institute of Mining Engineers; Col. Robert Clowry, president Western Union Telegraph Company; Mr. George G. Ward, vice-president and manager Commercial Cable Company; Mr. W. H. Baker, vice-president Postal Telegraph Cable Company; Mr. John Fritz, founder Bethlehem Steel & Iron Works; Mr. W. H. Fletcher, president Engineers' Club; Mr. A. B. Chandler, president Postal Telegraph-Cable Company.

Autographed souvenir menus have been prepared containing a colored photogravure of Mr. Edison and two original poems prepared by Mr. R. R. Bowker. The exercises will be as follows: Salutatory address by President B. J. Arnold; presentation of the medal fund and deed of gift by Mr. Samuel Insull, chairman of the Edison Medal Association; acceptance of same on behalf of the Institute by Dr. A. E. Kennelly, of Harvard University, past president; address on behalf of the colleges and universities by Prof. Cyrus F. Brackett, of Princeton University; address on behalf of the Association of Edison Illuminating Companies by President J. B. McCall; address on behalf of the National Electric Light Association by President Charles L. Edgar.

Mr. Edison has flatly declined to speak, but in response to the toast in his honor has agreed to send from the table a telegraphic acknowledgment. It is a great many years since he used the key. He will use one of the original quad sets built by him for, and loaned by the Western Union Telegraph Company. The message will be received in the banquet hall on a Postal quad of latest date by President A. B. Chandler, of the Postal Telegraph Cable Company, and will then be read to the audience. These arrangements are in the hands of Mr. C. P. Bruch, assistant general manager of the Postal system, and Mr. J. C. Barclay, chief engineer of the Western Union system. A number of special cable messages and telegrams will also be received at the same time.

The seating arrangements provide for the accommodation of eight persons at each table. Orders for seats should be sent in at once and should be accompanied by cash or check, payable to Mr. Ralph W. Pope, secretary. Price of tickets, without wine: Gentlemen, $7; ladies, $5; admission to galleries, $1. In order to secure accommodation, responses should reach Mr. Pope not later than February 9, 1904, 95 Liberty Street, New York. Mr. Arthur Williams, chairman of the committee on decorations, has made elaborate preparations for ornamenting and illuminating the ball room, and the effect will be very pretty and appropriate.

A Striking Tesla Manifesto.

We reproduce herewith in slightly reduced fac-simile the first page of a four-page circular which has been issued this week by Mr. Nikola Tesla in a large square envelope bearing a large red wax seal with the initials, "N. T." At the back of the page which we reproduce is given a list of 93 patents issued in this country to Mr. Tesla. The fourth page is blank. The third page has a little vignette of Niagara Falls and is devoted to quotations from various utterances of Mr. Tesla. The first of these is from his lecture delivered

New York, January 1, 1904

I wish to announce that in connection with the commercial introduction of my inventions I shall render professional services in the general capacity of consulting electrician and engineer.

The near future, I expect with confidence, will be a witness of revolutionary departures in the production, transformation and transmission of energy, transportation, lighting, manufacture of chemical compounds, telegraphy, telephony and other arts and industries.

In my opinion, these advances are certain to follow from the universal adoption of high-potential and high-frequency currents and novel regenerative processes of refrigeration to very low temperatures.

Much of the old apparatus will have to be improved, and much of the new developed, and I believe that while furthering my own inventions, I shall be more helpful in this evolution by placing at the disposal of others the knowledge and experience I have gained.

Special attention will be given by me to the solution of problems requiring both expert information and inventive resource—work coming within the sphere of my constant training and predilection.

I shall undertake the experimental investigation and perfection of ideas, methods and appliances the devising of useful expedients and, in particular, the design and construction of machinery for the attainment of desired results.

Any task submitted to and accepted by me, will be carried out thoroughly and conscientiously.

Laboratory, Long Island, N. Y.
Residence, Waldorf, New York City.

Nikola Tesla

PAGE FROM CIRCULAR SHOWING TESLA TOWER, WARDENCLIFFE, LONG ISLAND.

in 1893 before the Franklin Institute and the National Electric Light Association, as to transmission of intelligible signals and power to any distance without the use of wires. The second quotation is from his article on the problem of increasing human energy, which appeared in the *Century Magazine* in June, 1900, dealing with virtually the same subject. The third item quotes from his patents, Nos. 645,576 and 649,621, dealing with the transmission of electrical energy in any quantity to any distance, with transmitting and receiving apparatus movable as in ships or balloons. The circular is an extremely interesting one. It is most sumptuously got up on vellum paper and altogether constitutes a manifesto worthy of the original genius issuing it. It is to be gathered from the circular that Mr. Tesla proposes to enter the field of consulting engineering, in which he already has enjoyed an extensive connection here and abroad.

Three-Wire Direct-Current Railway System.

THE country in the neighborhood of Grenoble, suituated as it is in the Alpine region to the southeast of France, is justly renowned for its picturesque scenery, and this part of the Dauphiné is visited by numerous tourists every year. On the other hand, a certain number of villages, especially those lying in the picturesque valley of Gresivaudan, were lacking in a good means of communication. Owing to these reasons it was considered desirable to construct an electric railway system which should start from Grenoble and take in a number of the suurounding localities. Hydraulic power, which is already used to such a large extent for operating electric plants in the Grenoble region, was called upon here to give the necessary current for the plant.

The line which has been recently constructed starts from Grenoble and runs to the town of Chapareillan, covering a total distance of 26 miles. It gives tourists an opportunity to admire the natural beauties of the country and its advent has been warmly welcomed by the inhabitants of the different localities, as it has given a great stimulus to the commerce and industry of the region.

The Grenoble system presents a novel feature in the use of the direct-current, three-wire system for supplying the motors of the cars. The trolley line is double and constitutes the two outside wires of the system. The middle wire is connected to ground. The motors work

FIG. 1.—MAP OF LINE.

two in series upon 1,200 volts between the trolley wires. The middle connection between the motors is grounded.

Up to the present the maximum voltage which has been employed for direct current traction systems in Europe varies from 550 to 650 volts. The limit of tension, which is relatively small, kept the section of copper which is needed for the circuits at a high value. While the three-wire system now effects a considerable saving in copper for lighting and power circuits, it has not been applied to any extent upon electric traction systems, and therefore a description of the Grenoble-Chapareillan road may prove not without interest.

The tension of the overhead line at the terminals is 1,200 volts, the third or neutral wire being connected to the ground by means of a copper cable of 125 square millimeters section which is connected to the rails of the track, this forming the return circuit.

After leaving Grenoble the traction line crosses the Isère River and follows along its right hand. Besides a number of small villages, it supplies the stations of Meylan, Montbonnot-St. Martin and St. Ismier. It crosses the torrent of Manval over a metallic viaduct of 50 ft. length, and passes through Bermin, Crolles and Lounet. After crossing the torrent of Bresson by a stone-arched bridge 40 ft. long, it passes through St. Vincent de Mercuze and Barraux, and finally arrives at the terminus at Chapareillan after crossing the stream of

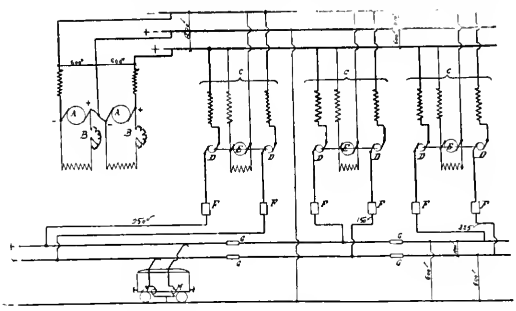

FIG. 2.—DIAGRAM OF CIRCUITS.

the Cernon over a steel bridge of 32 ft. As will be observed, the construction of the line has not required a great amount of engineering work, but steep grades have been frequently met with. The altitude of Grenoble is about 212 meters above the sea-level. The highest point of the line is at La Flachère, which is situated at 423 meters above sea-level. The difference of level between these two points is thus more than 200 meters. It is in the neighborhood of La Flachère that the heaviest grades are encountered.

The total length of the traction line is 26 miles. The overhead line consists of two hard-drawn copper wires 9 millimeters in diameter stretched at a distance of 28 inches apart. The line is supported by bracket poles or by suspension wires which are stretched across the track from poles or rosettes. At the crossing points, four overhead wires have been established, as also at the larger stations along the line, in order to allow the cars to be easily switched. The portion of the track which has been laid within the city of Grenoble is constructed of grooved rails on the Broca system weighing 80 pounds per yard. Outside the city the track is laid with rails of the railroad type which weigh 50 pounds per yard. The line is of one meter gauge throughout the entire length. Special care has been given to secure the proper bonding of the rails.

The motor cars and trailers for the Grenoble line have been constructed by the Compagnie Française du Material de Chemins de Fer, at the large establishment at Ivry, near Paris. The cars have been fitted out by Schneider & Company, of Creusot. The motor cars are of the usual tramway pattern with central passage and side seats, with sufficient motor capacity to draw two trailers of the same size or a freight car. These cars will contain 36 persons and their weight when empty is 9.2 tons. Each of the motor cars is equipped with two four-pole motors of the Thury pattern which have a capacity of 35-hp each. The motors are coupled in series and work at a tension of 1,200 volts. The starting switches and resistances are placed on the roof of the car and are operated from the motorman's platform by a hand-wheel and transmission system. The two ends of the car are symmetrical so as to avoid turning the car about at the terminal stations. When the car comes to the end of the line, the motorman detaches his hand wheel and carries it to the other platform. By putting it in place he makes an automatic connection which changes the direction of the current in the motors. The latter work on the single reduction system

The trains are made up usually of a motor car and two trailers, and are equipped with hand and electric brakes, which are applied on all the cars. The electric brakes can either receive their current from the overhead line, or the motors themselves are used as brakes, in which case the latter are operated as dynamos on short-circuit. The passenger cars are electrically lighted and heated. In this case the current is taken from only one of the overhead wires. The car carries two trolleys which use the ordinary type of pole; the trolley itself consists of a sliding cross-bar which is pressed against the overhead wires by a spring giving a pressure of 22 pounds. The present plant is laid out so as to secure the continuous operation of 9 trains of 30 tons each, comprising 8 trains for passengers and one freight train. Of the latter several different types of cars are now in use as well as a combination freight and passenger train.

The generating station which supplies the entire line is situated at Lancey, a small village about 10 miles from Grenoble and along the line of the road, but distant from it by three kilometers, lying on the other side of the Isère River. The water is taken from a hydraulic establishment which has been already installed by M. Berges. It affords a head of water of 1,470 ft. with a large available supply of power. The water arrives at the new hydraulic station of Lancey by a high-pressure penstock of riveted sheet iron, at a pressure of about 600 pounds per sq. in. It is distributed to the turbines by a large collector conduit which is placed outside of the station building. From the main conduit a separate branch runs into the building to supply each of the turbines. The latter, which are of the centrifugal type, are provided with gate-valves of special construction in order to take up the high water pressure.

The turbines, which have been built by Brenier and Neyret, of Grenoble, one of the largest French constructors, are at present three in number, of which one is used as a reserve. Each of these turbines has a capacity of 340-hp and operates at 325 revolutions per minute. These turbines are provided with speed regulators which keep the speed nearly constant at varying loads.

As the turbines use a considerable water supply, it became very difficult to measure the water which passed through them by a direct method. M. Berges adopts an indirect method by which a fractional part of the water is measured. The water coming from the turbines passes into the bottom of a large funnel-shaped recipient and mounts to the top. The upper portion of the vessel is cylindrical and is pierced with 80 rectangular openings or windows which are disposed around the periphery. These openings have been carefully calibrated to the same size and the lower edges are all on the same line. The water which arrives in the reservoir will flow out of the openings, and the height of the water in the opening gives an indication of the volume of flow. The system thus gives 80 streams of water, all alike, seeing that the size of the openings is equal.

FIG. 3.—OVERHEAD CONSTRUCTION.

One of these streams is then used to measure the volume of the total flow. The stream which is chosen for the purpose is sent through a water-meter of suitable construction and it only remains to multiply the reading by 80 in order to obtain the final result.

The station is equipped with three railway generators which deliver continuous current for the line. These generators, which have been constructed by Schneider & Company at the large Creusot works (France) are direct-coupled to the turbines which have been previously mentioned. They are of the Thury type with the hexagonal form and consequent pole disposition which is characteristic of this system. These machines have a capacity of 420 amperes and operate at 600 volts. The field, which has 6 poles, is compound wound. The fine wire winding of the field circuit has in series with it a rheostat for the field regulation. An automatic Thury electric regulator is used to operate this rheostat, and keeps the difference of potential at the bus-bars constant.

The two generators which are employed for the tramway lines are coupled in series, with a neutral wire coming from the middle connection, so as to produce a difference of potential of 1,200 volts between the end bars of the switchboard, of 600 volts between each of the outside bars and the middle. The distribution switchboard of the machines carries the apparatus which are generally employed in traction plants, together with some special devices which are needed for working the two machines in series on the three-wire system. The middle or neutral bar of the switchboard is connected directly with the tramway rails, which serve as a return conductor. The connection is made by a cable having a section of 125 square millimeters copper.

FIG. 4.—MOTOR CAR AND TRAILER.

From the bars of the switchboard start three groups of two feeders each, for supplying the traction line. In consequence, the feeding points are three in number and the cables are connected in at the points where the consumption of current and therefore the drop in the line is the highest. These points occur at Grenoble and Chapareillan, the ends of the traction line, and at Les Drogeaux, near the middle. In order to compensate automatically for this drop in the line, each of the feeders is made to pass through a booster group which is composed of a motor and two generators which give the extra voltage.

The motors of the booster groups are connected across the end bars of the switchboard, or upon 1,200 volts. Their fields are compound-wound and the motors are thus able to operate at a nearly constant speed under varying conditions of load. The motors vary in size and horse-power according to the number of volts which the generators they drive are required to furnish for the boosting action. The Grenoble feeder requires 360 volts, and the Chapareillan feeder 225 volts. The third feeder connecting in at Les Drogeaux needs but 150 volts additional. The booster set for the Grenoble feeder is composed of a motor which drives two generators having a total capacity of 80-hp. The second group uses a 56-hp set consisting of a motor which drives two four-pole generators and gives 225 volts. The group for the Les Drogeaux feeder is similar, but gives only 40-hp. In all these groups the generators which serve as boosters are direct-connected to the motors by Rafford elastic couplings and work at constant speed. The generators are series wound.

Before connecting with the traction line the feeders pass through a second switchboard where connection is made with the booster circuits. The switchboard carries the measuring and regulating apparatus which are usual in such case; among others, a set of automatic circuit-breakers placed on the feeders protects the boosters against overloads or short circuits. An automatic mechanical device is used with the boosters. Each machine carries at the end of the shaft a governor which comes into action should the boosters tend to rotate in the opposite direction. It throws the armatures of the boosters in short-circuit in the case where the motor is disabled, so as to prevent the generators from acting as motors under the current which they receive, in which case they would have a tendency to race, seeing that they would then work under no load. Improved lightning arresters of the Thury pattern give an efficient protection of the circuits. These lightning arresters are formed of a long articulated arm, which carries a set of teeth on the extremity and breaks the circuit by drawing out a long arc.

The general arrangement of circuits for the Grenoble system is shown in the diagram, Fig. 2, where *A* is the compound-wound generator; *B*, automatic rheostat for generator; *C*, booster group; *D*, series booster; *E*, compound-wound booster of motor group; *F*, automatic circuit breaker; *G*, section insulator; *M*, car motor.

The main three-wire circuit which will be noted in the upper part of the diagram, starts from the Lancey hydraulic station, crosses the railroad line on a special bridge and then traverses the isère River which is about 400 ft. wide at this point. The three-wire circuit is formed of 6 conductors of bare copper, having a section varying from 125 to 65 square millimeters and a return cable of 125

FIG. 5.—END VIEW OF A CAR.

square millimeters section. A telephone line which unites all the tramway stations and posts of the sytem follows the same traject. All the conductors are supported by double porcelain insulators which are fixed upon metallic poles of the André system.

The above description will serve to bring out the main features of this somewhat novel system of traction lines. The operation of the road from the start has proved eminently satisfactory, and does credit to the system of direct-current motors and generators which has been designed by M. René Thury and which are now in successful operation in a large number of European plants. The use of boosters in connection with a plant of this kind will also be remarked as somewhat of a novelty.

N. E. L. A. Convention Date.

The date of the twenty-seventh annual convention of the National Electric Light Association has been fixed by the executive committee. The meeting will be held in Boston May 24, 25 and 26, a very agreeable period of the year in that vicinity. The name of the hotel selected as headquarters has not yet been announced.

Legal Conditions of Co-operative Telephony.

A very interesting decision as to the rights of a member of a "co-operative" telephone company has recently been given by the Supreme Court of the State of Indiana in the appeal of Arthur B. Irvin against the Rushville, Ind., Co-operative Telephone Company. The lower decision in favor of the company was sustained. The company has been for more than eight years past engaged in carrying on a general telephone business in the city of Rushville, Ind., and had, at the time of its organization, adopted the plan of allowing patrons who desired telephone service to become stockholders in the company, to purchase and own their own telephones, and to purchase and own their own wires leading from the location of their said telephones over the pole lines of the defendant to its exchange, and to pay a rental at the end of each month of a sum sufficient to pay the operating expenses of said company. Under this arrangement the plaintiff purchased and paid for one share of stock in said company, purchased a first-class telephone, and also paid for a line of wire leading from his residence to the local switchboard. A dispute arose over the monthly payment and at last Mr. Irvin was cut off. The points are enumerated clearly below summarizing the decision, which is of more than usual interest:

"Where, in an action against a telephone company for refusing to furnish plaintiff with switchboard connections, the complaint did not allege that there had been any discrimination against plaintiff's 'business,' it did not state a cause of action within Burns' Rev. St. 1901, §5529, providing that no telephone company shall discriminate against any individual or company engaged in any lawful business.

"A rule of a co-operative telephone company that all moneys due from its patrons for toll-line connections are payable on or before the 5th day of the month succeeding the maturity of the indebtedness, and, if not paid, the service of the delinquent patron shall be disconnected until the indebtedness is paid, is a reasonable regulation, which the company is entitled to enforce.

"Where a telephone company had promulgated a rule that claims for service must be paid on a particular day on pain of having the patron's service refused, and the patron was charged with notice of the rule, and with the fact that he had violated it, the telephone company was justified in refusing service without informing him at the time of its refusal as to its reason therefor.

"Where a telephone company had established and promulgated a rule requiring payment of previous tolls on a particular day on pain of having the service discontinued, the mere fact that the company had not enforced such rule against third persons before cutting off plaintiff's service for non-compliance therewith did not, of itself deprive the company of its right to enforce the rule against plaintiff.

"Where a public telephone company had promulgated a rule requiring payment of past tolls by subscribers on a particular day on pain of discontinuance of service, it was entitled to enforce payment of such dues and tolls by denying service, regardless of the fact that the subscriber claimed that the company was indebted to him to an amount exceeding the tolls due.

"Where, in an action to recover a statutory penalty against a telephone company for cutting off plaintiff's service for its failure to comply with a rule requiring payment of past tolls on a particular day, the complaint alleged that the rule had not been enforced as against 35 other patrons of the company who 'were in like situation with the plaintiff,' but did not allege that such other patrons were in default, or had refused to pay, it was insufficient to show a discrimination against plaintiff in the enforcement of the rule prohibited by Burns' Rev. St. §5529.

"Plaintiff owned stock in a co-operative telephone company, together with his telephone instrument and his line of wire to the exchange. Plaintiff was entitled to exchange connections on payment of certain tolls, and was subject to a rule providing that the company might discontinue connections for failure to pay past tolls on a specified date. Plaintiff, claiming that the company was indebted to him in excess of tolls claimed, refused to pay the tolls, and his service was discontinued. Held, that such discontinuance did not deprive plaintiff of his property without due process of law."

A New Wireless Telegraph System.

A Washington dispatch states that the Department of Agriculture has perfected a system of wireless telegraph which differs both from the Marconi and De Forest systems. The system, it is stated, is now in successful operation between San Francisco and the Farallones Islands, a distance of about 27 miles.

On the Wave Length of Free Vibrations in Antennae and Closed Oscillating Circuits.

By Dr. James E. Ives.

CERTAIN experiments on the wave lengths of antennæ and of closed circuits, which I have recently made on behalf of the De Forest Wireless Telegraph Company, appear to me to be of sufficient general interest to warrant their publication. They deal with the change in wave length produced by inserting turns of a wire helix in the antenna, or in a closed circuit, and also with the reaction between a closed circuit and the antenna. All the experiments described were made at the De Forest station at the Hotel Castleton, Staten Island, N. Y.

The measurements of wave length were made with an instrument designed conjointly by Dr. Lee De Forest and the author. The details of its construction, the method of calibrating it and the manner of its use will be described in another article. The experiments may best be discussed by referring to the figures and diagrams.

Fig. 1 shows the effect of inserting turns of a wire helix in the antenna. A diagram of the connections is shown in the right-hand lower corner of the figure. *e* is the earth wire, going to the ground plate; *a*, the aerial wire passing through the roof of the station, and *h* is the helix. *a* consisted of two No. 14 wires about a foot apart, and 62 ft. long; *e* of a single wire about 27 ft. long. The total length of the antenna, measured to the earth plate was, therefore, about 89 ft. The helix had a diameter of one foot, and consisted of 21 turns of No. 14 wire, an inch apart.

The curve shown in the figure is very nearly a straight line, as

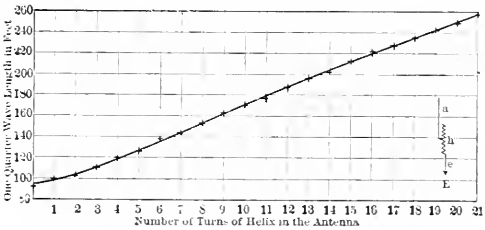

FIG. 1.—CURVE SHOWING EFFECT OF PUTTING TURNS OF HELIX IN ANTENNA.

might have been expected, since the wave length of the antenna varies as the square root of its inductance, and its inductance varies roughly as the square of the number of turns inserted. This may be stated mathematically as follows:

Let v represent the velocity of light or of electric waves in air.
n, the frequency of the electrical oscillations in the antenna.
λ, the wave length of the oscillation.
T, the period of the oscillation.
L, the inductance of the antenna.
C, its capacity.

Then since

$$v = n\lambda \tag{1}$$

$$\lambda = \frac{v}{n} \tag{2}$$

and since

$$n = \frac{1}{T} \tag{3}$$

and

$$T = 2\pi\sqrt{LC}, \tag{4}$$

$$\lambda = 2\pi v\sqrt{LC}. \tag{5}$$

But

$$L = k^2n^2, \text{ approximately,} \tag{6}$$

where k is a constant, depending upon the shape and size of the helix. Therefore,

$$\lambda = 2\pi v k n \sqrt{C} \tag{7}$$

But C, the capacity of the antenna, may be considered a constant for an antenna of a given height, since the potential loop being at its free end and the node at its base, the charge that it holds will not be much affected by putting in turns of a helix near its base. Therefore,

$$\lambda = n \times \text{constant} \tag{8}$$

Fig. 2 deals with a closed oscillating circuit made up of four Leyden jars in series, and a certain number of turns of the helix

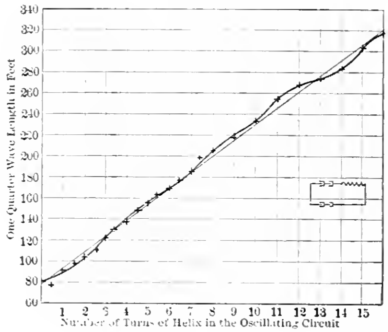

FIG. 2.—CURVE SHOWING EFFECT OF ADDING TURNS OF HELIX TO A CLOSED CIRCUIT.

already described. It shows how the wave length of the circuit is changed by adding turns of the helix. The quarter wave length is plotted as a function of the number of turns inserted. The curve varies irregularly on both sides of a straight line. For the reasons

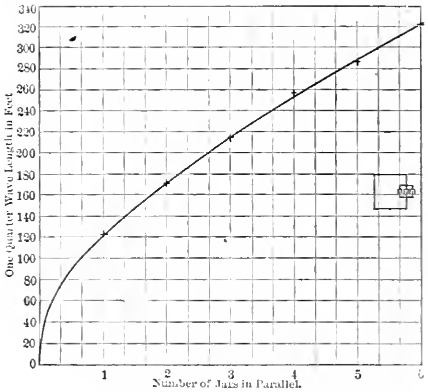

FIG. 3.—CURVE SHOWING EFFECT OF INCREASING THE CAPACITY OF A CLOSED CIRCUIT.

already given we should expect it to approximate to a straight line, since the wave length should be approximately a linear function of the number of turns inserted.

Fig. 3 also deals with a closed circuit and shows the effect upon its wave length of changing the number of Leyden jars inserted in

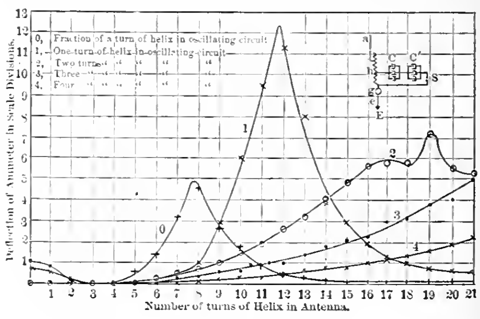

FIG. 4.—CURVE SHOWING RESONANCE OF ANTENNA WITH THE OSCILLATING CIRCUIT.

parallel. In this case the capacity of the circuit is changed, while its inductance is kept constant. The curve obtained is parabolic in form, as might be expected from equation (7), where it is seen that if the inductance remains constant the wave length of the circuit will vary as the square root of the capacity.

Fig. 4 is perhaps the most interesting curve of the series. As shown by the diagram of the circuits (in the right-hand upper corner of the figure), the antenna and the closed circuit are linked together, so that certain turns of the helix are common to both. The spark-gap is placed in the closed circuit, and the electrical disturbances set up in this circuit are, therefore, communicated to the antenna through the linked portion of the helix. The curve shows that the oscillating current in the antenna may be greatly increased by bringing the antenna into resonance with the closed circuit.

In the diagram, *a* is the antenna proper; *h* the helix already described; *e* the earth wire containing the hot-wire ammeter, *g*, on which the current readings were taken; *c* and *c'*, two sets of three Leyden jars, and *s* a spark-gap. The spark-gap was excited by an induction coil. The experiment was made by putting a certain number of turns of the helix in the closed circuit, and then varying the

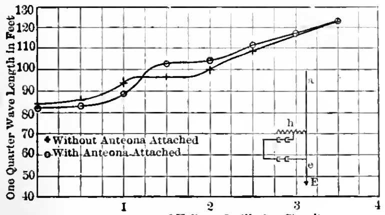

FIG. 5.—CURVE SHOWING EFFECT OF A LINKED ANTENNA ON WAVE LENGTH OF A CLOSED CIRCUIT.

number of turns in the antenna from 0 to 21. Five sets of readings were made giving the five curves shown in the figure. It is evident from the figure that for the cases of 3 and 4 turns in the closed circuit, more than 21 turns would have to be inserted in the antenna to

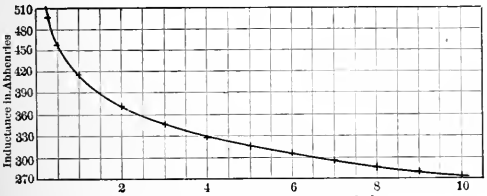

FIG. 6.—CURVE SHOWING RELATION BETWEEN THE INDUCTANCE OF A WIRE ONE FOOT LONG AND THE DIAMETER OF THE WIRE.

bring it into resonance with the closed circuit. The irregularity of the peak of curve 2 is perhaps due to the presence of an overtone.

Fig. 5 shows the results of an experiment made to determine how the wave length of a closed circuit is affected by a linked antenna.

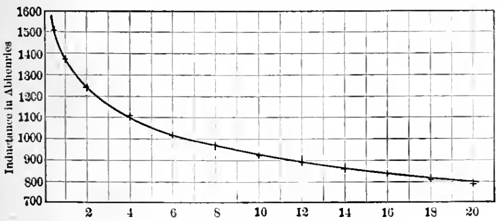

FIG. 7.—CURVE SHOWING RELATION BETWEEN THE INDUCTANCE OF A CIRCLE OF WIRE ONE FOOT IN DIAMETER AND THE DIAMETER OF THE WIRE.

The wave length of the closed circuit was first measured without the antenna attached, and then with it attached. The character of the closed circuit was varied by changing the number of turns of the helix. The connections are shown by the diagram in the lower right-hand corner of the figure. The solid and dotted curves respectively give the wave lengths for the two cases. It will be noticed that the two curves cross each other for a quarter wave length of 96 ft., which was the quarter wave length of the antenna as used in this experiment, i. e., without any turns of the helix. It will be noticed in the figure that for three and a half turns of the helix in the closed circuit, the two curves come together. For any number of turns greater than this it was found that the two curves still coincided. It therefore follows that when the wave length of the antenna is in the neighborhood of that of the closed circuit, the wave length of the closed circuit is decreased or increased by the linked antenna, according as the wave length of the oscillating circuit is less or greater than that of the antenna.

Figs. 6, 7 and 8 give theoretical and not experimental data. Fig.

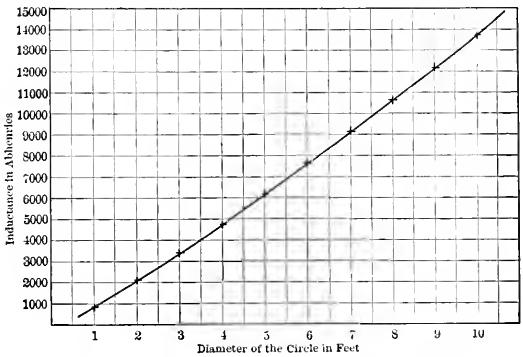

FIG. 8.—CURVE SHOWING THE RELATION BETWEEN THE INDUCTANCE OF A CIRCLE OF NO. 10 WIRE AND ITS DIAMETER.

6 is a calculated curve showing the relation between the inductance of a wire one foot long and the diameter of the wire. The diameter of the wire is given in one-hundredths of an inch, and the inductance in abhenries, or absolute units. The curve was calculated from the formula for rapid oscillations,

$$L = 2l \left[\log_e \frac{2l}{\varrho} - 1 \right]$$

where l is the length of the wire, and ϱ its radius, both in centimeters. This curve can be used to calculate the inductance of a single-wire antenna of any length and diameter.

Fig. 7 is a calculated curve, showing the relation between the inductance of a circle of wire one foot in diameter, and the diameter of the wire. The diameter of the wire is given in one-hundredths of an inch, and the inductance in abhenries. The inductance was calculated from the formula for rapid oscillations,

$$L = 4\pi R \left[\log_e \frac{R}{\varrho} + .08 \right]$$

where R is the radius of the circle, and ϱ the radius of the wire, both in centimeters.

Fig. 8 is a calculated curve showing the relation between the inductance of a circle of No. 10 wire and the diameter of the circle. (The diameter of No. 10 wire is .102 inch.) The diameter of the circle is given in feet, and the inductance in abhenries. This curve was calculated from the same formula as Fig. 7.

My thanks are due to my assistant, Mr. James B. Gottsberger, for his assistance in these experiments, and for plotting the curves.

Paris Subway Charms.

A cable dispatch to the newspaper press from Paris, dated January 23 says: "Vital statistics published lately concerning the Paris Metropolitan are not likely to encourage New Yorkers to seek jobs on Manhattan's new subway unless better conditions prevail. The figures show that since the Metropolitan was established, four years ago, no less than 50 per cent. of the employees have died, been killed or have left on account of bad health. The publication of statistics has started another spasm of reform, which may have permanent result in good." We think New York's subway will be able to do better than this.

The Measurement of Distributed Leakage on Transmission Lines.

BY FRANK F. FOWLE.

THE line insulation of circuits employed in various kinds of transmission often determines one of the limits of commercial operation. Especially is this true as regards the effect of weather on very long lines of bare wire. On short lines the requirements of insulation are usually prescribed by considerations of electrical balance, stray foreign currents, lost energy, electrolysis and fire risks. On very long lines the requirements of insulation are usually prescribed by the permissible attenuation of energy. With bare wires the limiting weather conditions will determine the maximum attenuation.

There being no sources of potential in the leakage paths, the leakage will depend on the state and the material of the insulating covering on the wire, on the size, shape and frequency of the insulating supports and on the specific resistance, and the surface conditions of the supports. On long lines insulated wire is usually employed only at places exposed to injurious gases or contact with foreign wires or objects. On long aerial lines the leakage resistance is practically concentrated in the thin films of matter on the surfaces of the insulators. Dry wood is a very fair insulator if it has not been treated by any preserving process. Under wet weather conditions the poles and cross arms become conducting, to a very considerable extent, in those portions penetrated by moisture. The practice of fastening iron wires to the poles with staples, from the top to the butt below ground, as a protection from lightning, considerably increases the leakage in wet weather, in the case of circuits having earth returns. The surfaces of the insulators, which are dry under all conditions, constitute the constant part of the insulation resistance and these surfaces should be of maximum length and minimum breadth. Direct escape into the atmosphere is probably very slight except where saturated vapors of a conducting nature are encountered.

The number of insulating supports per mile varies from twenty-five to fifty; it may be assumed without question that the leakage on long lines is uniformly distributed. The methods of measuring insulation resistance are based on the laws of distribution of current and potential, in the steady state, on a uniform line possessing resistance and leakage. Consider a line of length l, of uniform resistance r, and leakage conductance g per unit length. The leakage conductance is the reciprocal of the leakage resistance per unit length.

If r = resistance in ohms per mile,
g = leakage conductance in mhos per mile,
l = length of the line in miles,
E = the potential of the line at any point x,
I = the current at the point x, the fundamental equations are:

$$-\frac{\delta E}{\delta x} = r I \tag{1}$$

$$-\frac{\delta I}{\delta x} = g E \tag{2}$$

whose solution may be derived as follows:

$$\frac{\delta^2 E}{\delta x^2} = -r\frac{\delta I}{\delta x} = r g E \tag{3}$$

$$\frac{\delta^2 I}{\delta x^2} = -g\frac{\delta E}{\delta x} = r g I \tag{4}$$

$$\therefore \quad E = A\,\varepsilon^{\beta x} + B\varepsilon^{-\beta x} \tag{5}$$

where A and B are the arbitrary constants of integration and ε is the base of the Naperian system of logarithms.

$$\frac{\delta^2 E}{\delta x^2} = \beta^2 E \tag{6}$$

from (5).

$$\therefore \quad \beta = \sqrt{r g} \tag{7}$$

From (1)

$$I = -\frac{1}{r}\frac{\delta E}{\delta x}$$

$$= -\frac{\beta}{r}\left(A\,\varepsilon^{\beta x} - B\,\varepsilon^{-\beta x}\right)$$

$$I = \frac{-A\,\varepsilon^{\beta x} + B\,\varepsilon^{-\beta x}}{K} \tag{8}$$

where

$$K = \sqrt{\frac{r}{g}}\,. \tag{9}$$

The distribution of current and potential in the line is now determined in so far as the properties of the line determine it. The conditions at the two terminals determine the constants A and B, and completely solve the problem. At $x = 0$, the home or sending terminal, assume an e.m.f. acting on the line through a resistance. From (5) we have,

$$A + B = E_0 - I_1 r_1, \tag{10}$$

and from (8)

$$\frac{-A + B}{K} = I_1 \tag{11}$$

where I_1 is the current through the resistance r_1, due to the e.m.f. E_0.

At $x = l$, the distant or receiving terminal, assume the line to be closed through a resistance r_2.

From (5) and (8) we have,

$$A\,\varepsilon^{\beta l} + B\,\varepsilon^{-\beta l} = I_2\, r_2 \tag{12}$$

$$\frac{-A\,\varepsilon^{\beta l} + B\,\varepsilon^{-\beta l}}{K} = I_2 \tag{13}$$

$$A\left(1 - \frac{r_1}{K}\right) + B\left(1 + \frac{\;}{K}\right) = E_0$$

$$A\,\alpha_1 + B = \frac{1 + \alpha_1}{2}\,E_0,$$

$$\text{where } \alpha_1 = \frac{K - r_1}{K + r_1} \tag{14}$$

$$A\left(1 + \frac{r_2}{K}\right)\varepsilon^{\beta l} + B\left(1 - \frac{r_2}{K}\right)\varepsilon^{-\beta l} = 0,$$

$$A\,\varepsilon^{\beta l} + \alpha_2\, B\,\varepsilon^{-\beta l} = 0,$$

$$\text{where } \alpha_2 = \frac{K - r_2}{K + r_2} \tag{15}$$

$$-B\alpha_1\alpha_2\,\varepsilon^{-2\beta l} + B = \frac{1 + \alpha_1}{2}\,E_0.$$

And finally,

$$A = \frac{-\alpha_2\,\dfrac{1 + \alpha_1}{2}\,E_0\,\varepsilon^{-2\beta l}}{1 - \alpha_1\,\alpha_2\,\varepsilon^{-2\beta l}} \tag{16}$$

$$B = \frac{\dfrac{1 + \alpha_1}{2}\,E_0}{1 - \alpha_1\,\alpha_2\,\varepsilon^{-2\beta l}} \tag{17}$$

The usual methods of measuring insulation resistance employ a battery and measuring apparatus at the home end, with an insulated or open terminal at the distant end. An exact method, presented later, employs both an insulated and a short-circuited terminal at the distant end.

When $r_2 = \infty$

$$\alpha_2 = -1 \tag{18}$$

and when $r_2 = 0$,

$$\alpha_2 = 1 \tag{19}$$

Also, when $r_2 = K$,

$$\alpha_2 = 0 \tag{20}$$

and

$$\left.\begin{aligned} A &= 0, \\ B &= \frac{1 + \alpha_1}{2} E_0 \end{aligned}\right\} \tag{21}$$

By an inspection of (11) and (20) it will be seen that the physical interpretation of K is the outgoing resistance of an indefinitely long line, measured at the home end. Also, if the line be cut at any point and closed through a terminal resistance equal to K, the distribution of current and potential will be the same as in the indefinitely long line, and as though the terminal did not exist. The coefficients α_1 and α_2 are termed coefficients of reflection.

In the general case the outgoing resistance of a line is, from (10) and (11),

$$K_1 = K \frac{A + B}{-A + B} \tag{22}$$

$$= K \frac{1 - \alpha_2 e^{-2\beta l}}{1 + \alpha_2 e^{-2\beta l}}$$

$$= K \frac{e^{\beta l} - \alpha_2 e^{-\beta l}}{e^{\beta l} + \alpha_2 e^{-\beta l}}$$

When $r_2 =$ and $\alpha_2 = -1$,

$$K_1 = K \coth \beta l. \tag{24}$$

When $r_2 = 0$ and $\alpha_2 = 1$,

$$K_1{}^1 = K \tanh \beta l. \tag{25}$$

The exact method of measuring insulation resistance consists in measuring the current and the potential on the line at the home end,

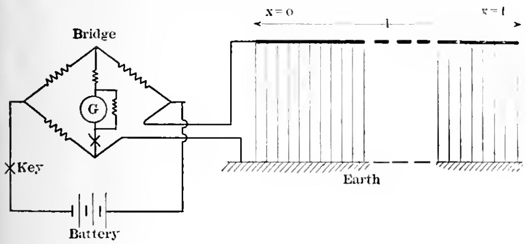

FIG. 1.

when the distant end is open or insulated and also when it is closed through zero resistance or short-circuited.

If K_1 is the measured resistance at $x = 0$, when $r_2 =$ and $K_1{}^1$ is the measured resistance when $r_2 = 0$, we have from (24) and (25):

$$\tanh \beta l = \frac{K}{K_1} = \frac{K_1{}^1}{K}, \tag{26}$$

$$K^2 = \frac{r}{g} = K_1 K_1{}^1 \tag{27}$$

and

$$g = \frac{r}{K_1 K_1{}^1}$$

or

$$R = \frac{K_1 K_1{}^1}{r} \tag{28}$$

where R is the insulation resistance in ohms per mile and r, K_1 and $K_1{}^1$ are expressed in ohms.

The bridge method consists in using the ordinary Wheatstone bridge for measuring K_1 and $K_1{}^1$, and the circuit employed is shown in Fig. 1.

When l and g are small, the approximate formula (29) may be used:

$$R = l K_1 \tag{29}$$

and only one reading is necessary. Readings should be taken with the positive and the negative poles of the battery to line. The average reading may be used in the formula. A marked discrepancy in the readings indicates a source of e.m.f. in the leakage paths. The objections to the method are the effect of earth currents or

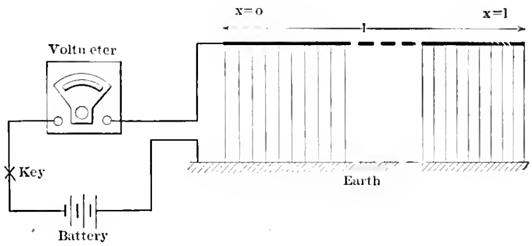

FIG. 2.

induced currents on the galvanometer and the time required to take readings.

The voltmeter method is simpler, quicker and requires less apparatus. It is necessary to know the voltage of the measuring battery and the internal resistance of the voltmeter. The procedure is the same as in the last method, readings being taken with $r_2 = \infty$ and $r_2 = 0$. The circuit is shown in Fig. 2.

Let the voltmeter reading be V_1 when $r_2 = \infty$, and $V_1{}^1$ when $r_2 = 0$. Then

$$K_1 = \frac{E_0 - V_1}{\frac{V_1}{r_1}} = \left(\frac{E_0}{V_1} - 1\right) r_1 \tag{30}$$

And

$$K_1{}^1 = \frac{E_0 - V_1{}^1}{\frac{V_1{}^1}{r_1}} = \left(\frac{E_0}{V_1{}^1} - 1\right) r_1 \tag{31}$$

where r_1 is the voltmeter resistance. Therefore, we have from (28):

$$R = \left(\frac{E_0}{V_1} - 1\right)\left(\frac{E_0}{V_1{}^1} - 1\right)\frac{r_1{}^2}{r} \tag{32}$$

It is interesting to note that the length of the line does not appear in the formula. It is necessary to know the line temperature unless r is measured on a very short section of the line at the time the readings, V_1 and $V_1{}^1$, are taken. Slight variations in temperature may be neglected; the necessary precision in the temperature, when r is computed rather than measured, may be obtained from the equation expressing resistance as a function of the temperature and the resistance at a standard temperature.

It sometimes occurs that there is additional resistance at $x = 0$, due to protective coils or lamps in the battery taps. In this case V_1 and $V_1{}^1$ must be corrected. If

$$r_1 = r_1{}^1 + r_1{}^{11} \tag{33}$$

where $r_1{}^1$ is the additional resistance and $r_1{}^{11}$ is the voltmeter resistance, we have

$$V_1 = V\left(\frac{r_1{}^1}{r_1{}^{11}} + 1\right) \tag{34}$$

where V is the actual reading and V_1 the true corrected reading.

It often occurs that there is considerable cable between the measuring apparatus and the aerial line. In this case it is safe to assume that the cable leakage may be neglected and the cable resistance be inserted as r_1^1 in equation (34). If there is leakage in the cable the case becomes that of two lines, having resistance and leakage of different magnitudes, connected in sequence. The general formulas (1) to (17) may be extended to cover this case, but the number of necessary readings would be increased.

If l and g are small the following approximation may be made, because the line drop, lr, is very small compared with the total leakage resistance, $\frac{1}{lg}$. When $r_2 = 0$, we have:

$$E_0 = V_1^1 + \frac{V_1^1}{r_1} lr = V_1^1\left(1 + \frac{lr}{r_1}\right) \qquad (35)$$

$$\frac{E_0}{V_1^1} - 1 = \frac{lr}{r_1} \qquad (36)$$

And substituting in (32) we get

$$R = lr_1\left(\frac{E_0}{V_1} - 1\right) \qquad (37)$$

where the length of the line appears, but the resistance does not. This is the well-known formula used in the method requiring only a single reading. The extreme conditions of insulation give

$$\left.\begin{array}{l} V_1 = 0 \quad \text{when } R = \infty \\ V_1 = E_0 \text{ when } R = 0 \end{array}\right\} \qquad (38)$$

In measuring metallic circuits, it should be noted that r is twice the resistance of one wire per mile. If earth potentials are troublesome, in measuring the insulation resistance to earth in the exact method, the voltmeter should be read with no battery in circuit, in order to obtain a correction for the observations.

Measurements on a metallic circuit, from each wire to earth and from one wire to the other, should show that

$$(R_1 + R_2) \geqq R_{12} \qquad (39)$$

if R_1 and R_2 are the insulation resistances to earth of the two wires, respectively, and R_{12} is the insulation resistance between them. R_{12} should always be measured with a battery to which there is no earth connection.

The number of variables in equations (32) and (37) make the work of plotting curves a laborious matter. Curves would be of little use because of the variation of r_1 in practical work. The calculation of a few actual cases will serve to illustrate the matter.

EXAMPLE I.

Take 50 miles of No. 12 (N.B.S.G.) copper wire; a voltmeter with a scale of 0 to 150 volts and a resistance of 15,000 ohms; a battery of 100 volts and negligible internal resistance compared with the voltmeter resistance.

$$\text{Then}\left.\begin{array}{l} l = 50. \\ r = 5.13 \\ r_1 = 15{,}000. \\ E_0 = 100. \end{array}\right\}$$

Assume $R = 100$ megohms per mile,
or $g = 10^{-8}$ mhos per mile.

By calculation it is found that

$\beta = 0.0002265$ from (7)
$\beta l = 0.01132$,
$K = 22{,}650$ ohms, from (9)
$K_1 = 2{,}000{,}000$ ohms, from (24)
$K_1^1 = 256.5$ ohms, from (25)
$R = 100{,}000{,}000$ ohms, from (28)
$V_1 = 0.7444$ volt,
$V_1^1 = 98.32$ volts.

The error in (37) is negligible. The precision of V_1 is very poor, but for most cases R is so great that its effect is negligible, as far as transmission is concerned.

EXAMPLE II.

Take the wire of example I and assume
$R = 10$ megohms per mile,
or $g = 10^{-7}$ mhos per mile.

By calculation,

$\beta = 0.0007162$ from (7)
$\beta l = 0.03581$,
$K = 7{,}162$ ohms, from (9)
$K_1 = 200{,}100$ ohms, from (24)
$K_1^1 = 256.4$ ohms, from (25)
$R = 10{,}000{,}000$ ohms, from (28)
$V_1 = 6.974$ volts,
$V_1^1 = 98.32$ volts.

The error in (37) is negligible in this case also.

EXAMPLE III.

Take the wire of example I and assume
$R = 1.0$ megohm per mile,
or $g = 10^{-6}$ mhos per mile.

By calculation,

$\beta = 0.002265$ from (7)
$\beta l = 0.1132$,
$K = 2{,}265$ ohms, from (9)
$K_1 = 20{,}080$ ohms, from (24)
$K_1^1 = 255.4$ ohms, from (25)
$R = 1{,}000{,}000$ ohms, from (28)
$V_1 = 42.76$ volts,
$V_1^1 = 98.33$ volts.
$R = 1{,}004{,}000$ ohms, from (37)

The error in (37) is $+ 0.4$ per cent.

EXAMPLE IV.

Take the wire of example I and assume
$R = 0.1$ megohm per mile,
or $g = 10^{-5}$ mhos per mile.

By calculation,

$\beta = 0.007162$ ohms, from (7)
$\beta l = 0.3581$,
$K = 716.2$ ohms, from (9)
$K_1 = 2{,}085$ ohms, from (24)
$K_1^1 = 246.1$ ohms, from (25)
$R = 100{,}000$ ohms, from (28)
$V_1 = 87.80$ volts,
$V_1^1 = 98.39$ volts,
$R = 104{,}300$ ohms, from (37).

The error in (37) is $+ 4.3$ per cent.

EXAMPLE V.

Take 150 miles of No. 9 (B. W. G.) iron wire, with the same voltmeter and battery.

$$\text{Then}\left.\begin{array}{l} l = 150. \\ r = 20. \\ r_1 = 15{,}000. \\ E_0 = 100. \end{array}\right\}$$

Assume $R = 1.000$ megohm per mile,
or $g = 10^{-6}$ mhos per mile.

By calculation,

$\beta = 0.004472$ ohms, from (7)
$\beta l = 0.6708$,
$K = 4{,}472$ ohms, from (9)
$K_1 = 7{,}638$ ohms, from (24)
$K_1^1 = 2{,}619$ ohms, from (25)
$R = 1{,}000{,}000$ ohms, from (28)
$V_1 = 66.25$ volts,
$V_1^1 = 85.13$ volts,
$R = 1{,}146{,}000$ ohms, from (37).

The error in (37) is $+ 14.6$ per cent.

For short lines of copper the approximate method of (37) is sufficiently precise for most purposes. If the exact method of (32) is used the precision in R is poor if R is great, owing to the great difference between K_1 and K_1^1. For iron lines of moderate length and all very long lines the exact method of (32) should be used. For a given value of g, the error in (37) increases as r and l increase.

A method for the exact measurement of R and r has been given by Heaviside[1], and is of interest in this connection. The existence of concentrated leaks or non-uniformly distributed leakage renders the above theory inapplicable and the formulæ incorrect, and the theory of such cases belongs more properly to the subject of location of faults.

Direct escape into the atmosphere or the insulating dielectric is ordinarily negligible. The resistance of such paths may be calculated when the form and the specific resistance of the conductors are known, as shown by J. J. Thomson[2]. If the static capacity per

[1] "Electrical Papers," by Oliver Heaviside, vol. I, page 41, "On a Test for Telegraph Wires."

[2] "Elements of the Mathematical Theory of Electricity and Magnetism," by J. J. Thomson, page 312, §§ 196 and 197, on "Distribution of Current Through an Infinite Conductor."

unit length is C and σ is the specific resistance of the dielectric:

$$R = \frac{\sigma}{4 \pi C} \quad (40)$$

For a grounded line,

$$C = \frac{1}{2 \log \frac{2h}{r}} \quad (41)$$

For a metallic line,

$$C = \frac{1}{4 \log \frac{d}{r}} \quad (42)$$

And for concentric conductors,

$$C = \frac{1}{2 \log \frac{r_2}{r_1}} \quad (43)$$

where r is the radius of a wire, h the height of a wire above the earth and d the distance between two wires. Therefore, we have, for a single wire with earth return,

$$R = \frac{\sigma}{2 \pi} \log \frac{2h}{r} \quad (44)$$

For a metallic circuit,

$$R = \frac{\sigma}{4 \pi} \log \frac{d}{r} \quad (45)$$

And for concentric conductors,

$$R = \frac{\sigma}{2 \pi} \log \frac{r_2}{r_1} \quad (46)$$

If σ is the resistance in ohms between parallel faces of a cubic centimeter of the insulation and the logarithms be taken to the base ten, expressions (44), (45) and (46) will be expressed in ohms per mile if multiplied by the constant,

$$1.431 \times 10^{-5} \quad (47)$$

The value of the constant is small, but σ is ordinarily very great. The data on the subject of direct escape into saturated vapors, from suspended wires, is very meagre.

Elihu Thomson on Aeroplanes.

Considerable public interest has been shown in the remarks made by Prof. Elihu Thomson at the recent Walker dinner to Prof. Langley, on the subject of aeroplanes. Those remarks have been variously twisted and misquoted. Through the kind courtesy of Prof. Thomson we are now able to gratify the interest of our readers by presenting a revised abstract. Prof. Thomson says:
